On the morning of Aug. 26 the battle opened at all points. In the centre, the Russian XV. Corps drove the 3rd Res. Div. into the woods to the W. of Hohenstein, but von Unger's Landwehr and Ersatz were hurried up from the southern frontier guard and, posted behind the barrier of the Drewenz at Mühlen, prevented a roll-up of the XX. Corps' left, while the 3rd Res. Div. rallied under cover of the woods. Thus the XX. Corps was enabled not only to hold on in front of Tannenberg against the Russian XXIII. Corps and part of the I. Corps, but to open an attack which brought its centre to Ganshorn and Thurau. Farther S. the German I. Corps, the principal element on which the projected "Cannae" depended, had not made the progress expected by Hindenburg. Its detrainment was not complete, and von François attempted to obtain a postponement of the attack; after some discussion, Ludendorff insisted that the corps should begin its attack at noon, and it did so at 1 P.M. But at that time it was too late to capture the heights of Usdau–Gross Tauersee as had been intended. Meantime Mühlmann, holding Strassburg and Lautenburg against the Russian 6th and 15th Cav. Divs.,—though he could not prevent an inroad, between these points, on the rear of von François's assembly area—pulled out his main body eastward to Heinrichsdorf, the capture of this point bringing him into line with von François.

In sum, the left of von Scholtz's forces was already bent back (though in no wise enveloped) by the Russians, and the German enveloping wing under von François was only at the beginning, instead of in the middle, of its task. From the point of view of Hindenburg's headquarters, this was not a satisfactory opening to a battle fought against time. But events on his left wing on Aug. 26 gave a new turn to affairs. The Russian XIII. Corps, approaching Allenstein, met with no opposition, and the VI. Corps, heading N. and seeking for liaison with Rennenkampf, suffered disaster. The latter had pushed its leading division as far N. as Gross Bössau, where it halted and entrenched. In this position it was found and attacked by Mackensen's XVII. Corps, while the 6th Landwehr Bde. and part of the 36th Res. Div. of Below's I. Res. Corps, N. of Lake Lautern, came in upon its rear. At nightfall it was broken by a charge of the Landwehr, and fled in disorder, seriously impairing the *moral* of the following division. Meanwhile the remainder of the German I. Res. Corps moved on Wartenburg. Thus, the Russians' extreme right was in rapid retreat, while their centre was advancing northward, and the Germans saw that the opportunity of double envelopment was not gone by, but only maturing. Accordingly, on the evening of Aug. 26, von François was ordered to attack the Usdau–Gross Tauersee position at dawn with the utmost energy, Mühlmann to push on from Heinrichsdorf on Borchersdorf. This achieved, the I. Corps was to advance as rapidly as possible on Neidenburg, flank-guarded to the S. by Mühlmann. Von Scholtz was to continue the attack of his centre eastward so as to cut off all Russian troops north of Gross Gardienen, while his right intervened in the battle at Usdau and his left held on at Mühlen and on the Drewenz. Mackensen was to pursue the beaten Russians due S. on Ortelsburg, while the movements of Below (whose 1st Res. Div. was already due E. of Wartenburg) and of von der Goltz (whose Landwehr Div. was to begin detrainment Aug. 27, E. of Osterode) were apparently left to their own discretion, since headquarters intended to trust themselves on Aug. 27 entirely to von François and von Scholtz.

On Aug. 27 was fought the battle of Usdau. Here the German I. Corps, well in hand and complete, and aided on its left by the right of the XX. (Schmettau's detachment) and on its right by Mühlmann, completely broke the Russian resistance. But whether through tactical accidents, or a misinterpretation of orders, or desire to obtain elbow-room to the southward, the I. Corps, instead of driving due eastward from the captured line, wheeled to its right, pushing the Russian I. Corps on to Soldau, and itself reaching at nightfall the E.–W. line Heinrichsdorf–Borchersdorf–Schönwiese. The XX. Corps (less Schmettau's detachment) drove on in the centre, and reached a N.–S. line from the E. end of the Mühlen See to Skottau, facing a new Russian position at Waplitz, where their XXIII. Corps, and also part of the force defeated at Usdau, rallied. Meantime there had been critical fighting farther north. West of the line Hohenstein–Paulsgut the Landwehr and Ersatz of Unger and the 3rd Res. Div. were heavily attacked by the Russian XV. Corps, and Allenstein, undefended, was occupied by the Russian XIII. Corps. At the German headquarters it was rumoured that Unger's line had been broken, and the 37th Div. was hurriedly taken from von Scholtz's advancing line and put in on the Drewenz, to prevent a break-through towards Osterode.

Such a break-through with the aid of the fresh XIII. Corps from Allenstein (which could hardly be held up for long by von

der Goltz's half-detrained division at Biesselen) was eminently possible, and could hardly fail to be disastrous to the Germans. Meantime 4½ German divs., pursuing the relics of two Russian divs. southward, had advanced to the region N. of Passenheim and of Ortelsburg, so far separated from the main body of the VIII. Army that liaison was maintained by aeroplane. It seemed that they, like von François, were missing the moment of wheeling-in for envelopment, and drawing off eccentrically. And on this day news came that Rennenkampf was at last beginning to advance from Insterburg–Angerburg. Already his cavalry was ranging the country behind Mackensen and Below; the Russian II. Corps from Angerburg was moving on Gerdanen, with a detachment in advance, threatening Lötzen from the rear; the IV. Corps on Friedland and Allenburg, and two others on Königsberg. Against such an advance as that of 4 cav. divs. and 4 inf. divs.—to consider only the troops S. of the Pregel—the two cav. bdes. of the German 1st Cav. Div. and the Lötzen Landsturm could not be expected to offer more than a trifling resistance. But if the situation of the Germans was critical, there was still the possibility, and even the necessity, of attempting the "Cannae" with the principal effort of encirclement made by the corps in the N. instead of by von François. The threatened westward movement of the Russian XIII. Corps could itself be taken in rear by bringing in the I. Res. Corps, while von Mackensen could close some, and von François, by an eastward extension of his left, others, of the routes behind Samsonov's XV. and XXIII. Corps. In any event some such movements were necessary if the two separated parts of the VIII. Army were to be got together, whether for offence or for defence. The crux of the problem lay in the direction to be given to von Mackensen—whether he was to continue southward and join hands with von François, forming the ring round the *whole* of Samsonov's army, or to bear up north-westward, behind the I. Res. Corps, and re-form N. or E. of Allenstein, ready either to coöperate in Below's envelopment of *part* of the Russians or to stave off Rennenkampf's advance on the Alle. In truth, this problem was too difficult for a definitive solution, and thus we find that Mackensen spent Aug. 28, first in marching from Passenheim to E. of Allenstein, and then in marching back, no doubt under successive instructions from headquarters.

The battle of Aug. 28, like that of Aug. 27, presented changing situations. As the Germans expected, the Russian XIII. Corps wheeled in from Allenstein, to coöperate with the XV. at Hohenstein, but, having been for days out of touch with the VI. Corps, and therefore ignorant of its rout, it assumed certain troops (Below's) seen to the N. of Wartenburg to be that corps moving on Allenstein. Thereupon, giving up the westerly direction to its supposed comrades, it turned sharp S.S.W. to assist the XIII. Corps more directly. If any particular moment can be fixed as the turning-point of the battle it is this, for it completed the confusion at Hohenstein. West of that point, on the morning of Aug. 28, Morgen's 3rd Res. Div. had advanced from the Jablonken Forest to the attack of the Russian XV. Corps without waiting for support from the 37th Div. on its left or Unger's men on the right. It had driven the defenders into the W. side of Hohenstein at the same time as von der Goltz's Landwehr Div., detrained on the previous day, entered it from the north. To right and left of Morgen, the 37th Div. and Unger were soon heavily engaged and advancing generally eastward. To the S. of the Mühlen See the German 41st Div., attacking alone on the front which had previously been that of the whole XX. Corps, was repulsed by the Russians posted at Waplitz and S. of it. The fight was already extremely involved when on the rear of von der Goltz came the leading bde. of the Russian XIII. Corps. But, while for the German command there was nothing to do but to "wait for Below as Wellington waited for Blücher at Waterloo,"—as a German staff officer has put it,—the Russian leaders were in reality in the worse position. They were out of touch with each other and with Samsonov. The commander of the XIII. Corps would not promise his companion of the [illegible] arrival of his whole corps at Hohenstein in less than [illegible] and the advanced brigade above mentioned, involved in fighting with the German 37th Div. as well as with von der Goltz, lost its way in the woods, units opening fire upon each other, and finally broke away in panic. In the evening, the perplexed commander of the XIII. Corps found Below on his flank and rear, and came to a standstill. The XV. Corps commander had already, after the ruin of the XIII. Corps, decided that he could not continue this offensive till the intervention of the rest of that corps next day, and made up his mind to retreat while his left was still protected by the Waplitz forces. And, late in the evening, both the XIII. and XV. Corps received orders from Samsonov to retreat at once. The German ring was now rapidly forming itself. Not only had Mackensen, when drawing off to the Alle as ordered, taken the precaution of leaving detachments at Passenheim and S. of Mensguth, but, above all, the German I. Corps had arrived at Neidenburg, and its advanced troops were well on the way to Willenberg.

At the outset of the battle before Soldau which von François had projected for Aug. 28, the Germans realized that little effort was necessary for the capture of that town; and Schmettau's detachment on the left of the southward-facing line was pushed westward on Neidenburg, preceded by cavalry, which, passing round Neidenburg by the S., made havoc amongst the trains and convoys of the enemy on the Willenberg–Chorzele road. Soldau was captured about 10 A.M., and leaving Mühlmann to guard it von François pushed his 1st Div. after Schmettau. Shortly afterwards he received orders to move his 2nd Div. on Rontzgen to relieve pressure on the retiring 41st Div., and this order was soon supplemented by one of general pursuit in the Lahna direction. By evening the corps was beginning to reap a great harvest of prisoners, guns and trains.

Before these events were fully known at the headquarters of the VIII. Army, the German commander seems, for a moment, to have given up hope of bringing about a great encirclement. The Supreme Command was notified that the victory was won, but that it was improbable that the "boxing-in" (*Einkesselung*) of the two northern corps of the enemy would succeed, and army orders for Aug. 29, issued at 5:30 P.M. from Tannenberg, directed a general pursuit eastward by the troops of the XX. Corps and I. Corps, while Mackensen, instead of closing the avenues of escape, was again to march off to the Alle, which he was to occupy between Guttstadt and Allenstein. The 3rd Res. Div. and the two bodies of Landwehr fighting in the Hohenstein area were to fall out of the pursuit and assemble in readiness for other employment. For Rennenkampf, heralded by his cavalry, was at last really on the move. Later in the evening, however, it became apparent that the two northerly Russian corps had not yet made off. Below's divisions, swerving S.S.W. before reaching Allenstein, came upon rear-guards of the XIII. Corps at Zaszdrocz and Thomsdorf, and enforced a stand. The opportunity of boxing-in was seen to be still open; and, taking the risk of ignoring Rennenkampf for yet another day, Hindenburg and Ludendorff issued new instructions, bringing Mackensen's corps back again to the eastern gates of the Russian lines of retreat, and stimulating von François to a farther advance. Driving inward, the I. Corps, on Jedwabno and Willenberg, and the XVII., on Malga and Kannwiesen, were to attack both flanks of whatever forces were retiring through the forests S. of Passenheim, and, if possible, to join hands and to close the ring. Meantime the I. Res. and XX. Corps, von der Goltz, Morgen and Unger were to continue the now concentric effort against the Russians between Thomsdorf, Hohenstein, and Wuttrienen, and especially to master the lake defiles E.S.E. of Hohenstein. These orders did not reach their destinations till Aug. 29; but the corps commanders were already in substance carrying them out, and, in particular, Mackensen had not begun to draw away to the Alle.

In the battle of Aug. 29 the envelopment became definitely tactical. On three sides German regiments and battalions pressed the retreating and now greatly disordered XIII., XV. and XXIII. Corps in the dense country lying between Hohenstein and Passenheim. Von François posted part of his forces at the forest outlets about Muschaken and pressed on his westernmost troops towards Jedwabno and Willenberg. Mackensen barred

the lake intervals S.W. of Passenheim and pushed his left to Malga. Meantime Ludendorff assembled all the German forces which were successively crowded out by the concentric advance, as the nucleus of a defence group to be posted along the lakes behind the Alle, at Allenstein and at Passenheim. But the next day severely tested the strength of the ring that had been formed round the Russians. Already on Aug. 29 a part of von François's Corps, which was barring the exit of the forest at Rettkowen, was hard pressed by the weight of the opposing forces that were seeking an outlet, and only the arrival of Mackensen's troops from Malga enabled the gate to be closed again. On Aug. 30, another gate, N. of Muschaken, was burst open from the inside, and the Germans holding it were made prisoners. Reënforcements, however, arrived on the German side, and the emerging columns were pushed back again into the forest. Finally, in the night of Aug. 30–1, a desperate attempt was made to break out by way of Kannwiesen and Puchalowken, but was repulsed. But it was at all times doubtful whether the gates would hold firm, for Mackensen had been ordered to keep the bulk of his forces about Passenheim ready for action toward Allenstein if required, and the southern and south-eastern parts of the ring were in some places no more than a chain of posts. Moreover, on Aug. 30, serious Russian threats were made from outside the ring. Not only did Rennenkampf advance to the line Preuss.-Eylau–Bartenstein–Bischofsburg, with cavalry raiding nearly to Allenstein, and not only did attacks develop on Lötzen, but Ortelsburg, now in rear of Mackensen's corps, was threatened from the S.E. (no doubt, by a rallied portion of the Russian VI. Corps), and, above all, the Russian 1. Corps and part of the XXIII., which had followed its retreat by Soldau, now resumed the offensive from Mlawa on Neidenburg, with the aid of parts of the newly arrived XVIII. Corps, while the Russian cavalry division farther W. again broke in behind the German dispositions. To meet this, von François had to face S. with part of his corps, while the rest, facing N., maintained the ring of investment against heavy attempts to break through from the inside; and army headquarters had to place at von François's disposal the forces that it was collecting for the defence of the lakes behind Allenstein. In the event, the crisis was mastered by energetic frontal attack on the head of the Russian I. Corps column, combined with an audacious threat to its left by Mühlmann's Landwehr and Ersatz from Soldau. In fact, the Russian counter-advances were not pressed with any vigour. Rennenkampf certainly, and the Mlawa force probably, had received instructions to withdraw after demonstrating in aid of Samsonov, for the headquarters of the Russian "N.W. Front" (General Zhilinsky) had been informed by Samsonov on Aug. 29 of his decision to retreat, and was quite unaware of the fact that he needed assistance to enable him to do so.

On Aug. 31, all crises being past, it remained only for the Germans to complete the capture of what was left of the Russian XIII., XV., and XXIII. Corps. As on the two previous days, the resistance of the Russians was stubborn, but there was no common action or higher leadership. Entangled in the woods, artillery and trains constantly blocked the way to the infantry, which, after making its way past them, had to attack forces of all arms unaided. Outside the forest, the Germans cut off at their leisure the long columns of transport vehicles which had headed the retiring movement. Hindenburg's victory, doubtful even as late as the afternoon of Aug. 30, was complete by the evening of Aug. 31. The Russian losses in killed and in evacuated wounded are unknown, but 92,000 wounded and unwounded prisoners, 300 guns and immense numbers of vehicles and stores remained in the hands of the Germans. General Samsonov, after wandering in the forest in search of a way of escape, broke up his staff, and, left alone, shot himself.

### II.—Battle of the Masurian Lakes, or Angerburg

During the battle of Tannenberg the Russian I. Army had advanced to within a menacingly close distance. On Aug. 28, and again on Aug. 29, the German VIII. Army headquarters had almost given up the effort of encirclement in order to form a northward and north-eastward front against Rennenkampf; and as soon as the victory was complete, no time was lost preparing to take the offensive, both with the strategical object of gaining a free hand for a campaign into Poland in concert with the Austrians, and with the political object of freeing East Prussia from hostile occupation. Reënforced by two corps (Guard Res. and XI.) and a cav. div. (8th Saxon) from the western theatre, Ludendorff planned to attack Rennenkampf as soon as the new corps had detrained and those engaged in the ring of Tannenberg had been sorted out. This process took some time. The defensive group that was being formed to face Rennenkampf on Aug. 29–30 had to be dissolved again so as to reënforce von François against the counter-attacks on Aug. 30 from the S., and to secure Mackensen's rear, threatened on that day at Ortelsburg. Thus, at the close of the battle of Tannenberg, the VIII. Army had to be completely regrouped before any part of it, except the I. Res. Corps, could engage Rennenkampf. But even on Aug. 31, before the end of the battle, there were indications that Rennenkampf's forward movement had been given up.

The Russian general had, in fact, advanced half his army against Königsberg and only two corps and three cav. divs. into the open country S.W. of Insterburg–Angerburg. One of these corps (the IV.) had advanced on a comparatively narrow front and reached Preuss.-Eylau and Bartenstein, while the other (the II.) from Angerburg had made a feeble attack on Lötzen with one brigade and advanced to the line Bartenstein–Bischofstein with the other three. The XX. Corps, on the Deime, N. of the Pregel, and the III. Corps on the lower Alle S. of it, had allowed themselves to be imposed on by local activity of the Königsberg Landwehr and Ersatz forces. The three cav. divs. working with the II. and IV. Corps had raided as far as Wormditt, nearly to Allenstein, and to Sensburg, but without doing serious damage to the road and railway system. Behind the front, res. divs. were coming up to set free the XX. and III. Corps, from the Königsberg front, and eventually to besiege that fortress. Other forces, both active and reserve, were assembling at Grajevo, and skirmishing was in progress between Russian light forces in this region and a detachment of East Prussian Landsturm at Ruvezanny and Johannisburg under Col. Bacmeister, which, like the Lötzen force, had remained in its own area undisturbed during the Gumbinnen and Tannenberg operations. On Aug. 27 Rennenkampf was informed that troops hitherto in front of him had been identified at Gelgenburg and Bischofsburg and Soldau, and he was instructed to help Samsonov by pushing his left wing as near to Bartenstein as possible, his cavalry towards Bischofsburg and the II. Corps towards Passenheim. On Aug. 29 he was ordered to send two corps to meet Samsonov, who was heavily engaged (in reality, practically encircled), and cavalry to Allenstein. But almost immediately this last order was cancelled, as the II. Army was understood at Zhilinsky's headquarters to be retreating. Rennenkampf thereupon drew back on Aug. 30–1 to the line Lower Alle–Allenburg–Gerdauen–Drengfurt. After some discussion between the chiefs of staff of the I. Army and of the N.W. front, Rennenkampf decided to make a stand on the line Wehlau–Deime–Ottenburg–Gerdauen–Nordenburg–Lake Mauer, so as not to enhance still further the crushing moral effect of Tannenberg. But he had no intention of allowing himself to be cut off in this position; and to secure his left flank he ordered a considerable part of the II. Corps to attack Lötzen. This order, executed in the usual tardy fashion, led to nothing, but the forces thus gathered in front of Lötzen proved, as will be seen, a fatal obstacle to the full realization of the German plan.

This plan was, in sum, a strong frontal attack by the left wing and centre of a long, deployed array, while the right wing broke out through the Masurian lakes at Lötzen, Arys and Johannisburg, against the left and rear of the Russians. The newly arrived Guard Res. and XI. Corps, and the I. Res. Corps, with the 6th Landwehr Bde., formed the left wing in the region N. of Allenstein, the XX. Corps the centre about Allenstein, the XVII. Corps and the I. Corps with the 3rd Res. Div. the right at Passenheim and Willenberg. On the extreme left, the

Königsberg mobile force was to coöperate from the Deime line. The 1st and 8th Cav. Divs. grouped themselves in front of the right centre. The Landwehr and Ersatz units which had fought at Tannenberg were formed as a corps under von der Goltz (Goltz's Division, the new 35th Res. Div. formed of Unger's and Mühlmann's troops, and the 70th Landwehr Bde.), with the mission of capturing Mlawa (which was accomplished on Sept. 4), defending the southern frontier in positions in advance of that point and of Willenberg, and prolonging the defence eastward as the battle progressed.

The German forces, inclusive of one division of von der Goltz's corps, consisted, apart from cavalry, of about 16 divs.; those of the Russians, including troops which came into action from Grajevo, 14–16 divs. (II., III., IV., XX., XXII. Corps and 4–6 res. divs.). As usual, the Russian divs. were superior in infantry; the German, in artillery strength.

The battle opened generally on Sept. 7. On that day and the two following days the frontal attack of the Germans made only slow progress, the Guard Res. Corps approaching Allenburg, the I. Res. Gerdanen, and the XX. Angerburg. One div. of the last named, originally kept back as army reserve to add weight to the decisive attack, had to be returned to the corps to enable it to progress in the Mauer See region. Farther to the S., the XVII. Corps, utilizing the gate of Lötzen, sought to debouch on Kruglanken, but the Russians, having intended to attack Lötzen, were in strength here, and the advance of this part of the German enveloping wing was arrested. Army headquarters now possessed no reserve, and to open the way for the XVII. Corps there was no alternative but to swing the greater part of the I. Corps sharply northward instead of northeastward. Thus delay was imposed on the striking wing of the attack; and when, on the night of Sept. 9–10, Rennenkampf decided to take down his line from right to left and retired eastward on Wirballen, Suwalki and Augustowo, it was already unlikely that the Germans would be able to place any important forces across the enemy's lines of retreat in time. Nevertheless, a great effort was made to achieve this result. The German I. Corps had advanced in three columns, the 2nd Div. by Nikolaiken on Arys, the 1st Div. by Johannisburg on Bialla, with the 3rd Res. Div. on its right moving in the same direction. Von der Goltz, like Mühlmann in the Tannenberg operations, drew out his troops eastward as the 3rd Res. Div. advanced, keeping a closed group on that side and thinning the cordon at Mlawa and Willenberg. On Sept. 7 the German 2nd Div., after passing the defile of Nikolaiken, had become engaged at Gurra, N.E. of Lake Spirding, with a strong force of the Russian II. Corps that was ranged in a semicircle, facing W. and S. in the Arys defile. To enable the 2nd Div. to debouch, the 1st Div., leaving the combat in the Bialla direction to the 3rd Res. Div., swung up to the N. to attack the S. face of the Russian semicircle at Arys. On Sept. 8 the Russian resistance was broken by the combined attack, and a brigade of the 1st Cav. Div. attached to the I. Corps struck out northeastward to Klaussen. Meanwhile the 3rd Res. Div. had captured Bialla on Sept. 7th and pushed on to Drygallen on the Lyck road on Sept. 8, flankguarding towards Grajevo until the arrival of troops of von der Goltz's command enabled it to concentrate again.

On Sept. 9 the reunited I. Corps, master of the Arys defile, and joined by the two cav. divs. of the army, continued its northward movement so as to take the opponents of the XVII. Corps in rear. These stood on the line Mauer See–Goldapgar See–Soltmahner See–Gablick See, blocking the defiles between lake and lake. The pressure of the I. Corps from the S. and the XVII. Corps from the front, however, forced the evacuation of this position in the evening, especially as the two German cav. divs. were working out into the more open country towards Goldap. The XVII. Corps was thus released, and the enveloping movements of the German right wing began on Sept. 10. But the frontal attacks had made little impression, and Rennenkampf's XX., III. and IV. Corps were not effectively held in the Angerburg–Gerdanen–Wehlau positions. On the night of Sept. 9–10 the order to take down the line was issued, and thereafter the German frontal attack became a general pursuit, sometimes interrupted by stubborn rearguard fighting. By Sept. 11 the Guard Res. Corps had already fallen out of the scheme and was being grouped N.E. of Wehlau in reserve. The Königsberg troops made for the E. side of Tilsit, to cut off the Russian force that had established itself there. But for the I. Res. Corps, the XI., the XX., and even for the XVII., the operation was a simple follow-up on the respective axes Insterburg–Pillkallen–Schirwindt; Nordenburg–Gumbinnen–Stallupönen; Angerburg–Darkehmen–Walterkehmen–Stallupönen; and Possessezn–Gawaiten–Wysztinice.

Ludendorff, while praising the achievement of the VIII. Army in covering 60 m. in four days against an enemy expert in rearguard tactics, criticizes the pursuit in general as over-eager and lacking in coördination of effort, especially on Sept. 11 when the situation of the XI. Corps led army headquarters to deflect the pursuit of the XVII. and I. Corps northward during some critical hours. Eventually, the XI., XX. and XVII. Corps all converged on Stallupönen and Kibarty; while farther N. the I. Res. Corps, moving in the last stages nearly E., came to a standstill about Wladyslawow. From Sept. 9 the German effort against Rennenkampf's left and rear was carried out entirely by the I. Corps and the cav. divs., while the 3rd Res. Div. and von der Goltz guarded the outer flank against intervention from Osowiec and Augustowo or Suwalki. On this wing the record of Sept. 10–3 is one of true manœuvre.

According to the army orders for Sept. 10, the rôle of the I. Corps was to flankguard the XVII. in its attempt to strike in on Rennenkampf's rear E. of Angerburg, no general retreat of the Russians from Angerburg–Wehlau having yet begun. Accordingly, the two divs. of François's corps were directed on the line Lissen–Pillacken; while the 3rd. Res. Div., which had taken the Lyck road on Sept. 9 instead of swinging up with the others, was to drive in its Lyck opponents and then take the direction Marggrabowa–Filipowo. The 1st and 8th Cav. Divs., which had reached Goldap over night, were to make for Gumbinnen. But in the evening of Sept. 10 it became clear at the German headquarters that the Russian retirement was in progress, and the positions of the German right wing just mentioned became the starting-points of an attempt to reach the enemy's lines of retreat.

On Sept. 11 the I. Corps was to advance with its right pushed forward, to Goldap, and thence S. of the Rominten Heath on Mariampol; the XVII. Corps along the N. side of Rominten Heath, on Wistyniec; the cav. divs. in advance against the Insterburg–Kovno routes. But at midday both corps were ordered to swerve inwards owing to difficulties in which the XI. Corps was supposed to have become involved near Darkehmen. As the right of the I. Corps was échelonèd forward, this move in effect crowded out the XVII. Corps, as well as diverting the I. Von François, however, was unwilling to give up the attempted encirclement, and only wheeled up one of his divs. from Goldap on Gawaiten, while the other pushed N.E. along the N. side of Rominten Heath to Tollmingkehmen—the route originally assigned to the XVII. Corps. Later in the day, the alarm at the XI. Corps' front having proved to be baseless, the I. Corps was again directed N.E. towards Pillupönen and Wilkowiszki. But the amplitude of the army wheel had been diminished by a corps front. Wilkowiszki, instead of being the objective of the XVII. Corps, had become that of the I. Only the cav. divs. were left to pursue the advance S. of Rominten Heath on Mariampol. Meantime the 3rd Res. Div. moved from Lyck on Marggrabowa, von der Goltz's Landwehr div. following on as a right échelon against interventions from the S.E. or E.

During Sept. 12 the two parts of the I. Corps had heavy fighting at Gawaiten, Tollmingkehmen and Baubeln with the advanced and flank guards of various Russian columns which were retreating through the country S. of Darkehmen and Stallupönen. All these were checked and deflected northward, but none was cut off, though by evening the right of the Germans had extended up to Pillupönen. Von François, under cover of his 1st Div.'s positions at Tollmingkehmen–Pillupönen, passed the whole 2nd Div. through the Rominten Heath (having only

small forces at Goldap and near Gawaiten), and thus prepared for a movement next day in force by Wistyniec and Pillupönen on Wilkowiszki. On Sept. 13 the corps carried out this movement, preceded and flanked by the 8th Cav. Div. which had passed round the S. of Rominten Heath. The 3rd Res. Div. from Marggrabowa was turned eastward on Suwalki and, correspondingly, von der Goltz pushed forces up to Marggrabowa. On Sept. 13, indeed, the German army headquarters still hoped to cut off a considerable part of the Russian I. Army. But this hope was disappointed. Pushing his forces onward as fast as possible on Sept. 13, François was unable to do more than cannonade Russian columns which from time to time passed across his front. On Sept. 14 the Russians were found in force at Wilkowiszki, and both divs. of the German I. Corps had to be deployed to dislodge them. But they were a rear guard and not a flank guard, and since the pursuit thus became a frontal one for the I. Corps, as it already was for the rest, the battle of the Masurian Lakes as such came to an end.

Whether the direct follow-up should be continued to the Niemen or the operation closed down was a question of strategy, not of tactics. The latter alternative was chosen. On the night of Sept. 14 the German positions were:—XI., XX. and XVII. Corps in the area round Stallupönen and Kibarty; I. Res. Corps at Wladislawow, with advanced forces to the N.E.; I. Corps and the cavalry at Wilkowiszki, with advanced troops at Mariampol and Pilwiszki; 3rd Res. Div. at Suwalki; the Guard Res. Corps was in reserve probably between Insterburg and Wehlau and the Königsberg force had reoccupied Tilsit. The protective forces under von der Goltz, to the right rear of the 3rd Res. Div. and along the southern front, extended from Marggrabowa to the Vistula. The posts of this long, thin line were advanced considerably to the southward by frequent minor operations, of which the most important were a demonstration against, and bombardment of, the defences of Osowiec by von der Goltz in the last ten days of Sept.; combats of the 35th Res. Div. about Mlawa, Sonsk, Przasnysz, Chorzele and Janowo (Sept. 12–21); and an expedition of the Thorn garrison, which captured Wloclawek on Sept. 21.

The German gains in the battle of the Masurian Lakes, although less than they had hoped for and not comparable with those of Tannenberg, were considerable. Rennenkampf had been beaten and forced back, if not in dissolution at any rate in disorder, practically to the Niemen. Strategic freedom had been secured to the Germans for a considerable time. East Prussia was cleared of the invaders, 30,000 unwounded prisoners and 150 guns being added to the trophies of Tannenberg.

### III.—The Masurian Winter Battle

During Oct., Nov. and Dec. 1914, while the centre of gravity of operations on the Eastern European Front had lain in Poland and West Galicia, the German VIII. Army, much reduced, had defended the E. front of East Prussia against the Russian X. Army (Gen. Sievers), while the S. front had been held, in advance of the political frontier, by bodies and posts of Landwehr, Ersatz and Landsturm. In order to drive the Germans as far away as possible from the sensitive region of Kovno–Grodno which they had approached in the battle of the Masurian Lakes, Sievers took the offensive in Oct. and Nov., and drove back the VIII. Army (commanded successively by von Schubert, von François, and Otto von Below) to the line of the lakes, the Angerapp, and the Schoreller Forest, where the advance came to an end and both sides stabilized their positions.

In Jan. 1915 the German Higher Command decided to reënforce the E. front of East Prussia by the XXI. active and the newly formed XXXVIII., XXXIX. and XL. Res. Corps, and the S. front by various units drawn from Poland, in order to undertake a great offensive against the Russian lines of communication with Poland (of which the X. Army of Sievers was, substantially, a flank guard), while defending the southern front of E. Prussia against attack by the strong Russian XII. Army on the lower Narew. The strategic objects of this offensive are discussed under Eastern European Front Campaigns; and in the present article, which narrates the operations from the tactical point of view, it is sufficient to note that the envelopment of Sievers's right, combined with pressure on his front and the driving of a wedge into his left, was the immediate tactical idea, while the seizure of Osowiec and a bridgehead E. of the Bobr–Narew line for ulterior operations was the strategic object, which was to be attained in the act of driving this wedge, and secured by the double envelopment and destruction of the Russian X. Army. It was one of the most ambitious schemes attempted during the World War, and all the more so as it was to be carried out in midwinter.

The position of the Russian front line was as follows: Its right rested on the Szeszupa at the point where that river meets the frontier; thence it continued across the W. part of the Schoreller Forest to Spullen, where it turned due S., and, passing just E. of Gumbinnen and just W. of Goldap, followed thence a sinuous line amongst the lakes to Arys. From Arys southward it followed the E. edge of Lake Spirding and the line of the river Pissek (or Pissa) to the region of Lomzha. But S. of Lake Spirding, in advance of Johannisburg and Kolno, Russian light forces occupied most of the Johannisburg Heath, with a front E. of Rudczanny–Turoscheln–Friedrichshof, which, curving into the E.–W. direction, made contact with the line of the Russian forces facing the S. frontier. North of the right wing of the X. Army, *i.e.* of the lower Niemen or Memel river, were only small outposts of the minor Russian group based on Shavli.

In the last days of Jan. the German reënforcements assembled behind the screen formed by the VIII. Army. This screen, from right to left, consisted of Bacmeister's detachment (Landsturm) and the 3rd Cav. Bde. in the Johannisburg Heath, the 2nd Div. with 5th Inf. Bde., 11th Landwehr Div., Lötzen garrison, 1st Landwehr Div., 3rd Res. Div., 10th and Königsberg Landwehr Divs., and 1st Cav. Div., with the 5th Guard Inf. Bde. as support. Of the reënforcements, three corps assembled behind the 1st Cav. Div. screen, unobserved up to the last moment by the Russians, while the XL. Res. Corps joined the 2nd Div. behind Lake Spirding. The XX. Corps, brought from Poland to Ortelsburg, was to be pushed gradually by Myszyniec to the region between Johannisburg Heath and Lomzha, and so to broaden the wedge that it was to be the duty of the XL. Res. Corps and 2nd Div. to drive. In sum, a front line thinly and uniformly manned was secretly to be thickened at two points, on the right between Rudczanny and Kurwien, and on the left astride the Tilsit–Stallupönen railway. On the right, the "wedge" prepared behind the screen of Bacmeister's Landsturm consisted of 3½ (eventually 5 to 5½) divs.; on the left, the enveloping force prepared under cover of the 1st Cav. Div. consisted of 6 to 6½ divisions. The allocation of 10 young and homogeneous divisions, out of a total of 15½ of all categories, to two attack sectors which together covered only 35 m. out of a 110-m. front, and the preparation of these masses behind a continuous line, mark the forthcoming battle, as compared with that of the Masurian Lakes, or even Lodz, as a first approximation to the typical World-War battle.

The VIII. Army and its reënforcements were formed into two armies, the VIII. (Otto von Below) having the front from the right to the Insterburg–Eydtkühnen railway (its left unit being the 10th Landwehr Div.), and the X. (General-Oberst von Eichhorn) from that railway to the extreme left. General-Field-Marshal von Hindenburg and his chief of staff, Lt.-Gen. Ludendorff, moved "General Headquarters, East" to Insterburg so as to direct operations on the spot. The instructions given to Below and Eichhorn in the directives of Jan. 28 and Feb. 5 indicated only the general tactical idea without (so far as known) any allusion to the ultimate strategic objective, and left the army commanders almost a free hand. This was, no doubt, inevitable, owing to the impossibility of regulating liaison in a rapid winter advance, but that very fact made it all the more desirable that the army commanders should be fully acquainted with the Higher Command's intentions. The sequel suggests that this was not the case. In sum, the directives laid it down that Eichhorn's left wing (from left to right, XXI., XXXIX.,

Res. and XXXVIII. Res. Corps) should be the enveloping force, the right of its attack-mass of 6 divs. being directed on Kussen and the left "making a wide turning movement on or N. of the river Memel" with Wilkowiszki as its objective. Below's right (XL. Res. Corps and reënforced 2nd Div.) was to attack from Kurwien and Rudczanny, with Kolno and Johannisburg as the first objectives. The intermediate forces (VIII. Army left, X. Army right, viz. the 3rd Res. Div. and the four Landwehr formations) were to bind their opponents by frontal activity. Below's attack was to begin on Feb. 7, Eichhorn's on the next day. Ludendorff himself has admitted that he "found it difficult to start the troops." Snowstorms blew from the E., deep snow and ice covered the ground and obliterated landmarks. Wheeled transport could scarcely move, yet the snow was often not firm enough for sledges. Shelter was rarely found in the advance, since the Russians burnt all villages and farms as they retired. In the later stages, thaw and rain converted the ice-hard ground into mud; the marshes which bordered the streams, great and small, became impassable for guns and transport.

The offensive of the right wing on Feb. 7, beginning in Johannisburg Heath, was delayed at first rather by the ground than by the enemy, but it encountered solid opposition on the line of the Pissek, and especially in front of Johannisburg itself, attacked frontally by the reënforced 2nd Div. But in the night of Feb. 7–8, the left division (80th Res.) of the XL. Res. Corps forced a passage at Wrobeln, and next morning the right (79th Res.) div. did so at Gehsen. Both almost immediately drew up to the N.E. with the object of clearing the passage for the 2nd Div. by threatening the Johannisburg defence in rear, the 79th Res. Div. meeting a Russian threat on its outer flank by putting out a temporary flank guard towards Kolno. Thus, from the outset, tactical incidents gave the offensive a north-eastward direction on Bialla and left Kolno out of its sweep. On the night of Feb. 8–9, after the stubborn defenders of Johannisburg had been enveloped and overcome, the attack reached Bialla and pushed out its 3rd Cav. Bde. northward to Drygallen. On Feb. 9 another difficult march brought the three divisions up to Drygallen (2nd Div.), Bialla (80th Res.), S. of Rollken (79th Res.). Next day began a series of fierce combats about Lyck, which, like those before Lötzen and Arys in the Sept. battle, imposed a fatal delay upon the attempt to envelop the Russian left. In this case, as has been noted above, such an attempt really formed no part of Ludendorff's scheme, which intended a break-through eastward for the furtherance of an ulterior object, and the orders had indicated the rôle of Below as "attack" (*angreifen*) in contradistinction to that given to Eichhorn, "envelopment" (*umfassen*). But in default of any expression in the directive of the intention of driving on to Osowiec, tactical instinct and training led the commanders, once they had found a flank, to wrap themselves round it.

On the northern flank, Eichhorn ignored the suggestion of a wide turning movement N. of the Niemen (Memel river), possibly because he distrusted the Russian roads, and massed his six attack divisions in front of the Schoreller Forest. In the days before the battle the Russian general seemed to have suspected the impending blow, for the cavalry screen of the Germans was several times tested by local attacks. But at the last moment the attention of the defence was drawn off by Below's attack; and when, on the morning of Feb. 8, the German XXI., XXXIX. and XXXVIII. Corps passed through the outposts, they met at first with little resistance. The Schoreller Forest was cleared on the first day. On Feb. 9 the Russian defensive and the state of the ground compelled the attack in general to slow up. But one bde. of the German XXI. Corps broke through, and pushed on in one long march of 29 hours to Wladislawów, which was carried by assault in the night of Feb. 9–10. Thereupon, finding even its defensive échelon turned, the Russian right wing fell back rapidly.

Sievers, in fact, followed the same general policy as Rennenkampf had done. His object in holding a forward line in East Prussia (moral and political considerations apart) was, firstly, to be in position to coöperate in the much larger offensive of the XII. Army contemplated on the southern front, and, secondly, to keep the Germans away from Kovno and Grodno. When, therefore, Hindenburg seized the initiative a month before the Russian XII. Army could be ready, Sievers began to take down his line from right to left as soon as his opponent's purpose became clear. This was on Feb. 9. Next day even the troops facing the Arys–Lötzen–Angerapp front began to withdraw, pivoting on the stubborn resistance of the III. Siberian Corps at Lyck.

Both retreat and advance were carried out with high speed, in spite of the ground and the weather. The six divisions of the German X. Army, soon joined on their right by the Königsberg Landwehr Div., pressed on, ahead of supplies and liaison. On the night of Feb. 10–1 the XXXIX. Res. Corps surprised and overran a Russian div. in Eydtkühnen and Wirballen; the XXI. Corps reached Wilkowiszki, and the XXXVIII. Res. Corps Stallupönen and Deeden. Eichhorn's army was already at right angles to Below's, and its right division (Königsberg Landwehr) was crowded out as early as Feb. 11 by the eastward advance of the VIII. Army's left. On the outer flank of the XXI. Corps, as it swung S. and intercepted the roads and railways leading to Kovno, protection against interference from that direction was provided, first by the 1st Cav. Div. and its attached infantry (5th Guard Inf. Bde.), and then by this Landwehr division sent across the rear of the line on Feb. 12–3. On the night of Feb. 12, the general line of the German X. Army and of the wheeling portion of the VIII. was:—XXI. Corps, Ludwinow and Kalwarja; XXXIX. Res. Corps, Lubowo; XXXVIII. Res. Corps, Wizajny–Szittkehmen–Rominten Heath; 10th Landwehr Div. in Rominten Heath (facing E.) and at Plautzkehmen; 3rd Res. Div., S.E. of Goldap; 1st Landwehr Div., Altenbude. Half of the last-named div. was withdrawn from the ever-contracting line in readiness for service S. of Lake Spirding. Fighting on this day was especially sharp about Rominten Heath and Lake Wystiniec, where, at the angle of the line, the Russian forces had to gain time for the withdrawal of their congested trains.

Meanwhile, at the pivot of this rapid wheel-back, the III. Siberian Corps was still holding positions on both sides of Lyck against the 4½ divs. of Below's right and centre. On Feb. 10 the German reënforced 2nd Div. and advanced guard of the 80th Res. Div. came up against an advanced position of the defence on the line of the villages of Karbowsken, Baitkowen and Miechowen. It was known to the XL. Res. Corps staff that Lyck would be stiffly defended, and the 79th Res. Div. had continued north-northeastward from Rollken in order to reach the left flank of the probable line of defence; and, to strengthen the effect of this movement, the remainder of the 80th Res. Div. was switched southward onto the same route as the 79th Res. On Feb. 11 all attacks by the 2nd Div., 5th Inf. Bde. and advanced guard 80th Res. Div. on the advanced position of Baitkowen failed, and the right column (reënforced 79th Res. Div.) only reached Prostken on the Lyck–Grajevo road, while on the other flank the 11th Landwehr Div. (forming, with the 1st and 10th Landwehr and the 3rd Res., a group under I. Corps headquarters) was brought to a standstill in front of the Russian positions along the northern half of a line of lakes which leaves the main Masurian Lake system at Widminnen and joins the Osowiec marshes at Rajgrod. On Feb. 12 a Russian counter-attack on the left of the German 2nd Div. at Thalussen was only checked by diverting to that field part of the 11th Landwehr Div., which was seeking to force the lake defiles farther N. at Woszellen. But, fearing attack from Prostken, the Russians that night drew back to the line Bartossen–Neuendorf nearer to Lyck, still holding Woszellen with their right.

Feb. 13 was the critical day. The Germans pressed sharply against the new front before Lyck and forced the defile of Woszellen, while their S. column carried out a wide-ranging manœuvre from Prostken. The remainder of the 80th Res. Div. was swung up N. astride the river Lyck, came into line with its advance guard (which, as noted above, had been engaged in the frontal battle of Feb. 10–2), and, passing on beyond the flank of the defenders of Neuendorf, developed a threat on the rear of Lyck itself. Meanwhile the 79th Res. Div., with the

3rd Cav. Bde., pushed eastward in the hope of seizing Rajgrod. There lay the left flank of the lake line, the gate to Augustowo, and the edge of the Osowiec marshes, and it was stubbornly defended. At this moment, when the 1st Landwehr, 2nd and 80th Res. Divs. were thoroughly involved in the Lyck battle, and the 79th Res. Div. was striving to break through at Rajgrod, Russian counter-attacks developed from the south.

The eastward driving of a wedge, originally intended, had become in fact a northward and northeastward attempt to envelop, with mere picketing of the southward-leading roads. Ludendorff, dissatisfied and anxious, had already begun to cut out parts of the converging line of battle in order to obtain forces which might even now provide a solid right face for a wedge, but these were not available on the spot when the crisis came. At first only the 4th Cav. Div., freshly detrained from Poland, could be put in front of the Russians advancing from Grajevo; and the situation was so serious that the 80th Res. Div., already engaged in the flank of the defenders of Lyck, had to be counter-marched to assist the cavalry. Thus when, late on Feb. 14, the Russians finally gave up the defence of Lyck and fell back all along the line it was only their rear guard, and not the whole III. Siberian Corps, that was sacrificed. At that moment the corps had successfully transferred the weight of its defence to Rajgrod, where the German 79th Res. Div. was completely held up. Moreover, the 80th Res. Div. and 4th Cav. Div. in front of Grajevo repulsed the counter-attack.

On this date, Feb. 14, the advance of Eichhorn and of the left of the VIII. Army had progressed day by day—the troops now far ahead of supplies but living on captures—till the right-angled line of Feb. 12 had become almost a semicircle. Already half of each of the 1st Landwehr and 3rd Res. Divs., and the 5th Inf. Bde. which had been working with the 2nd Div., were out of the line and available for other service, besides the Königsberg Landwehr Div. already transferred to the E. flank. In the semicircle the 79th Res. Div. and 3rd Cav. Bde. (shortly rejoined by the 80th Res. Div. from Grajevo) were before Rajgrod, the forces which had taken Lyck (2nd and parts of the 11th Landwehr Div.) at Sentken, the 11th Landwehr Div. at Kleszowen, half the 1st Landwehr Div. at Willkassen, half the 3rd Res. Div. and part of the 10th Landwehr Div. at Raczki, and the rest of the latter before Poddubowek; while of the X. Army the XXXVIII. Res. Corps was before Suwalki, the XXXIX. Res. Corps before Tatarak and Krasnopol, and the XXI. Corps at Sejny and N. of Berzniki. In the later stages of the drive stubborn resistance had been met, for, as the parts of the Russian X. Army drew closer together and their trains became congested, more time had to be gained by rearguard fighting. But no real relief-attack had developed against Eichhorn's outer flank, either from Kovno or from Olita, and in spite of at least one favourable lake position (that of Kalwarja–Simno–Sereje) there was no counterpart on this side to the resistance offered at Lyck. Thus the eastward-running lines of retreat had been successively lost, till only those leading to Grodno, and to Lipok, Krasnyboz and Sztabin on the upper Bobr, remained open; and the whole Russian X. Army (except on its left, which held out at Rajgrod) was herded, with its guns and transport, into the great forest of Augustowo.

Thenceforward the German operations, by force of circumstances, assumed the twofold form which the Higher Command had originally intended—the tactical encirclement of the Russian X. Army and the strategic penetration of the Bobr barrier. But for the latter it was already too late. Instead of being on the river itself, the Russian forces were well in advance of it, at Stowiski, at Grajevo and at Rajgrod, preventing a *coup de main*, and the thaw had reduced the marshes of Osowiec to a condition in which positions for siege artillery were not to be had.[1] Nor was the tactical envelopment of the Russians in Augustowo Forest achieved without an extremely hazardous manœuvre. Between Feb. 15 and 18 the operations may be described as the battle of Augustowo. Few battle-stories are more complicated.

[1] Railway guns were in any case unavailable, owing to the break of gauge at the frontier.

Having been joined by the 80th Res. Div. and the 4th Cav. Div. the 79th Res. Div. renewed its attacks on Rajgrod on Feb. 15, this time successfully. The 3rd Cav. Bde. on its right had already found its way round the S. side of Rajgrod and surprised the passage of the Augustowski canal S. of Augustowo; hither the 4th Cav. Div. followed, and the four brigades together strove to reach and bar the roads running from Augustowo southward and southeastward. On the opposite flank of the semicircle, the 31st Div. of the XXI. Corps drove on southward from the region E. of Sejny, although its outer flank almost skirted the Niemen, and reached Sopockinie (Feb. 15), barring there the most northerly of the routes leading from the forest into Grodno, but exposing its own rear to any resolute sortie from that fortress. These were the first movements towards converting the semicircle into a ring, and both then and thereafter the ring was exposed to attack from outside, against which it could scarcely have stood. The other divisions of the XXI. Corps and the XXXVIII. and XXXIX. Res. Corps meanwhile entered the forest from the N., except the 77th Res. Div., which seems to have been hastily detached to Sereje as a flank guard; for the 1st Cav. Div., 5th Guard Inf. Bde. and Königsberg Landwehr Div., already finding posts on the eastward routes at and N. of Simno, could do no more.

On Feb. 16 the battle W. and N. of Augustowo began. Here the Russians occupied a semicircular position between Bralobrzegi, on the canal to the S. of the town, and the village of Szczebra, on the marshy Bilzna stream to the N. of it. Augustowo itself, the most important road-centre of the region, lies in a defile formed by two E.–W. lake-chains. Behind the town, the routes to the N.E. and E. traverse this defile, then break with their respective directions over the lake-chains at the villages of Studzieniczna and Sajenek respectively. The position was attacked from the S.W. by the XL. Res. Corps from Rajgrod, the 2nd Div. on the Lyck road, and what was left of the 3rd Res. Div. and 1st Landwehr Div. (the 11th Landwehr Div. being taken out of the line on Feb. 15) on the Raczki road, while half of the 10th Landwehr Div. approached Szczebra from the N.W., and the other half, crossing the front of the XXXVIII. Res. Corps of Eichhorn's army, came down on the same point from the north. But already on the evening of Feb. 15 a brigade of the XXI. Corps from the extreme left of Eichhorn's line, after traversing the forest diagonally from flank to flank, had reached Studzieniczna and Sajenek, and it now stood there, barring the roads immediately behind Augustowo but itself completely isolated.

This was the strangest of many strange episodes in the final phase of the Masurian winter battle. When, on Feb. 14, General von Eichhorn's army bordered the N. edge of the great forest, Fritz von Below, the commander of the XXI. Corps, sent his 31st Div., as already mentioned, to the S., and his 42nd Div. southeastward, into the heart of the forest. On his right the XXXIX. Res. Corps, temporarily reduced to the 78th Res. Div., barred, without advancing, the northern exits, while the XXXVIII. Res. Corps at Suwalki (aided by part of the 10th Landwehr Div., VIII. Army) was forcing a way in from the N.E. corner. The general intention was thus to envelop those Russian forces remaining in the northern part of the forest. But, finding no great opposition, the 65th Bde. of the 42d Div.—the same brigade which had forced a way to Wladislawow six days before—pushed on ahead past Fronczi and Serskilas, and so arrived behind Augustowo, while the brigade following it (59th) halted about Serskilas.

Next morning, when the fighting W. of Augustowo was just beginning, the 65th Bde. made an effort to thrust itself into the human tide which flowed eastward from that town, and even put a battalion over to the village of Sajenek to bar the last exit. But the Russians were determined to keep open their line of retreat, and while the main part of the intrusive force was pinned to its ground at Studzieniczna, the detached battalion was overrun and destroyed. Meantime the Russians in the north part of the forest, who were now retiring, before Eichhorn's frontal attack, in the direction of Grodno, came upon the 59th

Bde. at Serskilas and Makarcze and forced it out of their path. But at Fronczi this brigade rallied, and again advanced against the flank of the Russian troops as they poured past, while from N., N.N.W. and N.W. the columns of the 78th Res. Div. (XXXIX. Res. Corps) and 76th Res. Div. (XXXIX. Res. Corps) pressed on their rear. Desperate group-to-group and man-to-man fighting went on throughout the afternoon of Feb. 16 and the day of Feb. 17, but with heavy losses the Russians succeeded in bringing a large part of their forces through. Only their rear-guards remained to meet the final concentric effort of the Germans on Serskilas in the night of Feb. 17, and no more than 700 prisoners were here taken by the attack. But the masses only escaped from the N.W. into the S.E. part of the forest. There they were better protected and nearer to Grodno, but this did not save them.

By that time, fighting W. and N. of Augustowo was over. The attacks of the VIII. Army had made little progress during Feb. 16; from sheer determination, or perhaps in ignorance of the presence of the German 65th Bde. in their rear, the defenders of Augustowo held out stolidly, to enable trains and troops to withdraw. But on the morning of Feb. 17 a decision was reached. Storming and rapidly bridging the Blizna, the half of the 10th Landwehr Div. on the Suwalki road forced a way into the town from the N. and the defence collapsed. On that day also, the 31st Div. of the XXI. Corps established itself solidly at Sopockinie and farther S. at Holincze, barring roads and paths from the northern forest towards Grodno, and securing itself only by pickets against counter-attack from the E. and S.E. Lastly this div. reached and barred the great road Augustowo–Grodno at Lipsk, whither the 3rd Cav. Bde. from the extreme right of Below's army made its way. On Feb. 18 the direct pursuit of the 2nd Div. and XL. Res. Corps, which had fought the battle W. of Augustowo, penetrated to this point, shouldering masses of the Russians off the road into the S.E. part of the forest. On Feb. 18, also, forces recovered from the now unnecessary flank guards facing Kovno and Olita (1st Cav. Div., 5th Guard Inf. Bde., 77th Res. Div.) came into the region of Sopockinie to strengthen the now complete, but thin, ring formed round the S.E. part of the forest, where four Russian divisions were penned.

Ignorant of details, but seeing clearly that the encirclement of Sievers's army had practically succeeded, "General Headquarters, East" now exerted themselves to carry out that part of the scheme which was concerned with the forcing of the Bobr. The tactical *dénouement* had taken place so far to the S. and so close to Grodno that there still seemed to be a chance of breaking through between Osowiec and Grodno, for the troops engaged in the fighting in the Augustowo Forest were close at hand, and a considerable number of units (11th Landwehr Div., half 3rd Res. Div., half 1st Landwehr Div., 5th Inf. Bde.) were already in reserve.

In the direct pursuit itself, the forces from Augustowo had reached Lipsk, Krasnybor, and Sztabin, and driven Russian rear-guards over the Bobr. The absence of any formidable counter-attacks from Osowiec suggested that the forces there had been weakened in order to support either the main battle or the troops opposing the advance of the XX. Corps towards Lomzha, or both. In spite of the time which had elapsed, therefore, it was decided to make the attempt, and Otto von Below with the VIII. Army headquarters was placed in charge of all troops (including the XX. Corps) engaged or to be engaged facing the Bobr, Eichhorn assuming control of the remainder. The prospects of success were, however, so small, owing chiefly to the prolonged resistance of the four Russian divs. in the forest, which bound a considerable force for some days, that, after some attempts to force the Bobr crossings, the project was given up.

When, on Feb. 18, the four Russian divs. (27th, 28th, 29th Inf. and 53rd Res. Divs.) were finally enclosed in that portion of Augustowo Forest lying between the Augustowo–Grodno road, the Augustowo–Niemen canal and the Wolkuschek stream, the task of reducing them to surrender was given to six German divisions. From the S. the 2nd Div. (protected in its rear by the Bobr fighting), from the E. the 31st and 77th Res. Div. (protected against Grodno by their own posts only), from the N. the reunited 42nd Div. and from the west the 76th Res. Div. (both of which had followed up after the Serskilas fighting) gradually pressed them onwards, till, after a last fierce counter-attack (coinciding with a sortie from Grodno), they were forced to surrender between Ljubinowo and the Wolkuschek, on Feb. 21. Including these, the total prisoners captured by the Germans in the Masurian winter battle were over 110,000, with some 200 guns. Strategically, the German victory was an isolated episode; but tactically it was complete. It was won in the nick of time, for in these last days the Russian XII. Army's offensive on the Narew front was beginning.

This was the last great battle fought in Masuria, but from time to time the German X. Army and the new Russian X. Army (created almost as soon as the old was destroyed) manœuvred and fought to and fro in the country between the frontier and the Niemen, till in Sept. 1915 the German general offensive took the war over the Niemen, and far to the east. (C. F. A.)

**MATHEMATICS** (*see* 17.878).—The progress of the 20th century has been accompanied by continued activity in mathematical research. Some of its branches (such as mathematical logic, or the analytical theory of numbers) have actually been created during this period; others (such as the theory of functions of real variables) have been entirely reshaped. The following notes on some of the more recent developments are to be regarded as supplementing the earlier series of mathematical articles in the 11th Edition of this Encyclopædia.

### (1.) Mathematical Logic and the Foundations of Mathematics

Any branch of mathematics appears to consist of propositions stating the properties of certain relations, such as *being in a straight line with*, or *being the sum of*, holding between certain entities, such as *points* or *numbers*. For example: "If a point $c$ is in a straight line with two other points $a$, $b$, and if a point $d$ is in a straight line with the two points $b$, $c$, then the point $d$ is also in a straight line with the points $a$, $b$"; or again: "The number A which is the sum of the numbers B and C is unique."

The business of the mathematician, like that of any other scientist, is: ($a$) to discover new properties; and ($b$) to reduce all known properties to dependence upon the smallest possible set (called the set of *axioms*). The mathematicians of the past used to regard the simpler propositions of their science (and in particular the axioms) as intuitively evident. On the other hand, they made it a principle to accept no new propositions, except those that could be deduced from the primitive axioms. A mathematical treatise thus consists of a chain of deductions from a small set of initial premises, about which very little is said. This character is an essential and permanent one, although the interpretation given to it may have changed.

The "foundations" of mathematics are constituted by: ($a$) the knowledge used in its deductions; and ($b$) its axioms.

Let us begin with ($a$). It might seem that, in order to understand a mathematical demonstration, one should at least know the meanings of the mathematical terms occurring in it; that no one, for example, could either invent or judge a geometrical demonstration without knowing what is meant by "point" or by "being in a straight line with," or an arithmetical demonstration without knowing the meanings of "number" or of "addition." But modern mathematics insists that this is not so, and appears almost to disown all acquaintance with the meanings of the apparently mathematical terms it uses. An author will declare, for instance, that by "being in a straight line with," or by "being the sum of," he does not mean anything definite, but any relation whatsoever which happens to give a true meaning to his axioms. "Points" and "numbers" become, in the same way, entirely indefinite and unknown sets of entities. Only logical, non-mathematical words and expressions, like "all," "some," "if," "there is," etc., retain a relevant meaning; axioms come to be taken as mere definitions of the mathematical terms occurring in them, and the whole work of mathematics becomes purely formal.

It may seem remarkable that this independence of demonstration from subject-matter, which is so fundamental that its absence in a demonstration can mean nothing but a flaw or an omission, should have taken so long to assert itself in mathematics; but the reason is simple. The older mathematics is full of unanalyzed assumptions. It is only very recently that mathematicians have succeeded in making their hypotheses explicit, though they have been trying to do so since the time of Euclid. Their ultimate success has naturally initiated most important reactions in philosophy. For (*a*), all proof is formal, and the philosopher may therefore abandon the hopeless task of constructing a theory of "non-formal" proof. And (*b*), the modern mathematician separates the mathematical matter from the logical form, and requires logic to give an analysis of the latter. This has inevitably brought about a complete "renaissance" of logical studies, as the Aristotelian logic was entirely unequal to the task, on account both of its unsoundness on many points and of its total omission of relations.

Mathematics thus comes to appear as a beautiful logical exercise, which consists in developing the implications of various sets of formal premises (*i.e.* premises where the terms, other than logical, are *variable*, or symbols without assigned meanings). It may be pointed out that the motive for the choice of these premises, as well as for drawing certain consequences preferably to others, must lie in the region of possible meanings which mathematics itself ignores. Yet there is also a sense of what is formally important and interesting, quite apart from any subject-matter; and this sense, akin to the aesthetic sense, is often what suggests lines of development, and even modifications of the sets of axioms hitherto adopted. Thus Weierstrass says truly that the mathematician is a kind of poet.

But it is clear that *some* of the possible and indefinite meanings of the mathematical terms and axioms, namely their ordinary meanings, are of fundamental importance in the fabric of the world. What are these meanings, and how do we know that they satisfy this or that set of axioms? Not even the "pure" mathematician can wholly ignore this question; for the compatibility (or independence) of two given formal premises can be proved only by discovering some meaning which makes both premises true (or one true, and the other false).

Modern research has brought to light a fact, the possibility of which had escaped all previous philosophy, namely, that the ordinary meanings of geometry and arithmetic are of totally different natures, the former being as entirely empirical as dynamics, while the latter is *a priori*. We shall say nothing here of the ordinary spatial meaning of geometry, as this meaning belongs to physics, and owes no part of its substance to pure reason.[1] But we may note that an arithmetical translation, or rather a variety of such translations, can be found for geometrical axioms. Thus all questions as to the compatibility and independence of these axioms can be treated in a purely arithmetical form.

We now pass to the ordinary meanings of the symbols of arithmetic (*see* 2.523). Negative, fractional, irrational, and complex numbers are often regarded as entities whose existence is postulated in order that certain problems should not remain insoluble. But it is possible to point out certain logical combinations of integers which possess all the advantages of these hypothetical entities.

Thus, $-n$ can be the relation of $x$ to $x+n$, while $+n$ is the converse relation. Again, the rational $m/n$ can be the relation of $x$ to $y$ which holds when $nx=my$. Take now all such rationals arranged in a series by order of magnitude (which is easily defined), and cut this series in two parts, any term of the lower part being inferior to any term of the higher part: then the lower parts of all possible cuts or sections can be taken as the real numbers. Irrational numbers correspond to those "sections" in which neither part has either a first or a last term. Finally, a complex number may be regarded as an ordered couple of real numbers. It is important to realize that the integer $n$, $+n$, $n/1$, the real $n$ and $n+0.i$ are entities of different structures, and that addition and multiplication, applied to different sets of entities, are different operations. The problem is to define these operations for each "extension" of number in such a way that the special properties of the new numbers result from the definitions, and that, at the same time, those among the new numbers which correspond to the old numbers (as, *e.g.*, $n/1$ to $n$) retain all the properties of the latter.

All arithmetic thus reduces itself to the arithmetic of the natural integers; and this has been shown by G. Peano to be deducible from five premises, in which "number" means "natural integer." These are: (1) 0 is a number; (2) the successor of any number is a number; (3) no two numbers have the same successor; (4) 0 is not the successor of any number; (5) any property which belongs to 0, and also to the successor of any number which has the property, belongs to all numbers. Three non-logical expressions occur in these premises, namely, *number*, 0, and *successor*. It was discovered independently by G. Frege and B. Russell that the ordinary meanings of all three expressions can be defined in terms of those very logical notions which are the constituents of all proof. There is no need to insist upon the importance of this reduction of number to logic. It required an elaborate analysis of the fundamental concepts of logic; it had to meet considerable technical difficulties; and the chain of definitions which lead from logic to arithmetic is in consequence very complex. We can give but a rough sketch.

It may perhaps first be noted that the logical nature of the fundamental notions of arithmetic need not come to us as a complete surprise. For it is clear that, since each concept has a determinate number of instances, numbers are as universal as concepts. Then the connexion between the number 0 and the logical notion of negation is obvious; and that between the number 1 and the logical notion of identity hardly less so. Finally, the fundamental arithmetic operation of addition might well have as its kernel the logical operation *and*. But let us pass to the actual definitions of the logical theory of number:—

DEFINITION 1: *A relation is said to be* one-one *when, if* x *has the relation in question to* y, *no other term* x' *has the same relation to* y, *and* x *does not have the same relation to any term* y' *other than* y.

DEFINITION 2: *One class is said to be* SIMILAR *to*, OR TO HAVE THE SAME NUMBER AS, *another, when there is a* one-one *relation of which the one class is the domain, while the other is the converse domain* (the *domain* of a relation being the class of those terms that have the relation to some term or other, its *converse domain* the class of those terms to which some term or other has the relation).

Now we think of a number as of a common property of a group of similar classes. But it is not clear that there is such a property, over and above the *relation* of similarity running through the group, just as it is not clear that there is a property of *direction* common to all the members of a group of parallels, over and above the *relation* of parallelism. A given direction need be nothing more than the group of all parallels to a given line; similarly, a given number need be nothing more than the class of all classes which *have* that number—that is to say, which are similar to any one member of the class. We accordingly adopt:—

DEFINITION 3: *A number is the class of all those classes that are similar to* (*or have the same number as*) *a given class.*

This definition is sufficient, at any rate, for all arithmetic purposes. But it will be noticed that it renders necessary to postulate the existence of *instances* of every number, in order to obtain an orderly arithmetic. This postulate is "the axiom of infinity."

The number of Definition 3 applies to all classes, *i.e.* to all concepts; it includes both finite and infinite integers. To obtain the special properties of the finite integers, we must restrict the definition to them; and to do that, we need a logical definition of finitude. A "finite" number is a number of which the "principle of mathematical induction" is true. More strictly, if we adopt:—

DEFINITION 4: 0 *is the number consisting of those classes that have no members;*

and (roughly):—

DEFINITION 5: *The successor of the number of a class* α *is the number of the class consisting of* α *together with* x *where* x *is any term not belonging to* α;

then we say:—

[1] See on this subject the philosophical works of Henri Poincaré; *Our Knowledge of the External World*, by B. Russell (ch. iv.); *The Principles of Natural Knowledge* and *The Concept of Nature*, by A. N. Whitehead.

DEFINITION 6: *A finite number is a number which possesses any property which belongs to* 0, *and also to the successor of any number which has the property.*

We can now prove all five of Peano's axioms, *i.e.* all the ordinary arithmetic of the finite integers, and so all the arithmetic of real and complex numbers, without assuming anything beyond the laws of logic and the axiom of infinity. Both geometry and arithmetic are purely formal, or logical, in their method of deduction. But the ordinary meaning of geometry makes it a branch of physics, while the ordinary meaning of arithmetic makes it the development of logic itself.

For the detailed development of arithmetic on a logical basis see G. Peano, *Formulaire de mathématiques* (1908); G. Frege, *Die Grundlagen der Arithmetik* (1884) and *Grundgesetze der Arithmetik* (1893, 1903); B. Russell, *The Principles of Mathematics* (1903) and *Introduction to Mathematical Philosophy* (1919); A. N. Whitehead and B. Russell, *Principia Mathematica* (1910, 1911, 1913).

(J. N.)

## (2.) THEORY OF NUMBERS

In the article "Number" (19.847) an excellent summary is given of the classical theory. Modern mathematics has seen the rise of a new theory, the "analytic" theory, which has developed with astonishing rapidity, and has almost monopolized the attention of arithmeticians.

(*a*) *Theory of Primes.*—The modern developments of the theory of numbers depend in the main on the application to the theory of the ideas of the theory of functions of a complex variable (*see* 11.301). It was in the theory of the distribution of primes that these ideas first bore fruit.

It is usual to write $\pi(x)$ for the number of primes less than $x$. It has been known since Euclid that the number of primes is infinite, that is to say that $\pi(x)$ tends to infinity with $x$. The central problem of the theory has been the determination of the order of magnitude of $\pi(x)$ when $x$ is large, and its solution is embodied in the *Primzahlsatz*, or "prime number theorem," expressed by the formula

$$\pi(x) \backsim \frac{x}{\log x}$$

where the symbol $\backsim$ expresses the fact that the ratio of the two functions tends to unity. This theorem, conjectured by A. M. Legendre (1798) and C. F. Gauss (about 1792), was first proved by J. Hadamard and Ch. J. de la Vallée Poussin in 1896. The real founder of the modern theory, however, was B. Riemann, who, in a famous memoir published in 1859, first indicated the road along which subsequent research has progressed. Riemann did not prove the prime number theorem; strangely enough, he did not mention it, his object being to obtain, not an asymptotic formula for $\pi(x)$ but an exact expression in the form of an infinite series. Nor did Riemann attain the goal at which he aimed, his analysis, profound and beautiful as it is, being altogether incomplete and inconclusive. But it was Riemann who first recognized where the key to the solution lay, viz. in the study of the "Riemann zeta-function"

$$\zeta(s) = \zeta(\sigma+it) = \Sigma n^{-s} = \Pi\left(\frac{1}{1-p^{-s}}\right)$$

(where $n = 1, 2, 3, \ldots$ and $p$ runs through the series of primes), considered as a function of the complex variable $s$. Riemann established some, and conjectured others, of the properties of $\zeta(s)$; one famous conjecture, that all the complex zeros of $\zeta(s)$ lie on the line $\sigma = \frac{1}{2}$, remains unsettled to this day.

Riemann's memoir bore no fruit for over 30 years, when the way was cleared by the researches of Hadamard in the theory of analytic functions (*see* FUNCTION, 11.301 *seq.*). These researches led Hadamard himself, de la Vallée Poussin, and other writers, to a proof not only of the prime number theorem but of very much more. Thus de la Vallée Poussin proved that the logarithm integral $\mathrm{Li}x = \int_2^x \frac{dt}{\log t}$ represents $\pi(x)$ with an error of lower order than $x(\log x)^{-k}$, where $k$ is any number however large. He also investigated the distribution of primes of a linear form $am+b$ or a quadratic form $am^2+bm+c$, where $a, b, c$ are integers without common factor, showing, for example, that the primes are, on the average, equally distributed between the various arithmetical progressions $am+1$, $am+2$, . . . ., as had been conjectured long before by P. G. Lejeune Dirichlet. There is a corresponding theory for the "prime ideals" of the "corpus" associated with any algebraic number. The analogue of Riemann's zeta-function was discovered by R. Dedekind, but it is only recently that, in the hands of E. Hecke and E. Landau, the development of the theory has been pushed to a point corresponding with that of the ordinary theory.

The outstanding unsolved problem of the theory is that of the determination of the order of the *difference* $\pi(x) - \mathrm{Li}x$. This problem is bound up essentially with Riemann's unproved hypothesis concerning the zeros of $\zeta(s)$. If Riemann's hypothesis is true, the maximum order of the difference differs from that of $\sqrt{x}$ by logarithmic factors only. In any case the difference assumes values *of either sign* which tend to infinity with $x$. This theorem, proved by J. E. Littlewood in 1914, disposes of the old conjecture of Gauss and B. Goldschmidt that $\pi(x)$ is always less than $\mathrm{Li}(x)$.

Apart from applications to the theory of primes, there is a large literature connected with the pure theory of $\zeta(s)$. It has been shown by H. Bohr, E. Landau and F. Carlson that (to put it roughly) nearly all the zeros lie very near the critical line; by G. H. Hardy and J. E. Littlewood that (equally roughly) a considerable proportion lie actually on it. But the hypothesis itself remains unproved.

(*b*) *Additive Theory.*—The "additive" theory of numbers includes Combinatory Analysis (*see* 6.752), Partitions (*see* 19.865), the theory of the representation of numbers by sums of squares, cubes, or higher powers, and so forth.

The central problem is that of determining (exactly or approximately) the number of representations of an arbitrary positive integer $n$ in the form $a_1+a_2+\ldots+a_s$, where the $a$'s are numbers of some special type (*e.g.* squares), and $s$ may be fixed or unrestricted, according to the particular problem envisaged. There is a fundamental difference between the "additive" theory and what may be called the "multiplicative" theory, in which the central idea is that of the resolution of a number into prime factors. Analytically, this difference expresses itself as follows: the multiplicative theory depends on the theory of "Dirichlet's series" of the type $\Sigma a_n n^{-s}$, the additive theory on that of power series $\Sigma a_n x^n$. A great deal of the additive theory is purely algebraic, and is intimately bound up with the theory of elliptic functions. This side of the theory (founded by L. Euler) has been developed to a high pitch by English mathematicians, notably A. Cayley, J. J. Sylvester, and P. A. MacMahon, while more recently the methods of complex function theory have been applied to the theory and an "analytic additive" theory has been founded. Among many curious results we may mention the theorem of S. Ramanujan, that the numbers of the unrestricted partitions of numbers of the forms $5m+4$, $7m+5$ and $11m+6$ are divisible by 5, 7 and 11 respectively.

One of the most remarkable problems of the additive theory is "Waring's Problem." It was asserted by E. Waring (1782) that any number $n$ is the sum of at most 4 squares, 9 positive cubes, 19 fourth powers, and, generally, $g(k)$ powers, where $g(k)$ is a number depending on $k$ alone and not on $n$. This problem (in so far as it simply asserts the existence of *some* such number $g(k)$, was solved by D. Hilbert in 1909. J. L. Lagrange (1774) proved that $g(2)=4$ (any number is the sum of 4 squares, and some numbers not of less), and E. Wieferich (1909) that $g(3)=9$ and $g(4)\leqq 37$. Only a finite number of numbers (probably only 23 and 239) require more cubes than 8 (E. Landau, 1908), while an infinite number require 4 at least; and only a finite number of numbers require more than 21 fourth powers (G. H. Hardy and J. E. Littlewood, 1921), while an infinite number require 16 at least; and asymptotic formulae for the number of representations have been found; but our knowledge of this field is still extremely incomplete.

The "empirical theorem" of Chr. Goldbach, that every even number is the sum of two primes, has also received a considerable amount of attention, but is still unproved. Among other unsolved problems of the same character may be mentioned that of proving the existence of an infinity of primes of the form $m^2+1$ or (more generally) $am^2+bm+c$. This problem is not to be confused with the problem of primes $am^2+bmn+cn^2$, solved by de la Vallée Poussin.

(*c*) *Miscellaneous Investigations.*—The work of Dirichlet and L. Kronecher on the approximation of irrational numbers by rationals has led to extensive investigations lying on the border line between arithmetic and analysis, developed above all by H. Minkowski under the titles of *Diophantische Approximation* and *Geometrie der Zahlen*. The central idea in this theory is that of the lattice (*Gitter*).

A lattice point (*Gitterpunkt*) in space of any number of dimensions is a point with integral coördinates, and most difficult and fascinating problems arise when we consider the number of lattice points which lie within a volume of specified form in $n$-dimensional space. Thus Minkowski proved that any convex figure in space of two dimensions with symmetry about a centre, its centre at a lattice point, and of area 4, includes other lattice points besides its centre; with a whole series of corresponding theorems concerning more general configurations. Another class of lattice-point problems is exemplified by the "circle" problem of Gauss and W. Sierpinski, that of determining approximately the number of lattice points inside the circle $x^2+y^2=n$ when $n$ is large. A first approximation is naturally given by $\pi n$, the area of the circle, but the estimation of the error is a problem of exceptional difficulty. This problem and the analogous problem for the hyperbola $xy=n$ (Dirichlet's divisor problem) were connected with the theory of $\zeta(s)$ [see (*a*) *supra*] by Landau. These problems also are susceptible of manifold generalization. And in all these problems, we observe the dominating and irresistible tendency of modern higher arithmetic, the tendency to abandon its ancient tradition of isolation and assimilate itself so far as possible to the theory

of functions. in order to utilize the immensely powerful weapons which the latter theory alone can provide.

There is one famous problem in which no such reduction of arithmetic to analysis has been effected. "Fermat's last theorem" asserts that there is no integral solution of $x^n+y^n=z^n$ (other than the trivial solution $x=z$, $y=0$) for any value of $n$ greater than 2. It was the attempt to prove this theorem that led to the whole development of the theory of algebraic numbers; but, in spite of the widespread attention which it has excited, and the extreme importance of the general theories of which it has been the starting point, the theorem itself remains unproved, though important additions have been made recently to our knowledge by A. Wieferich, D. Mirimanov, L. E. Dickson, and H. S. Vandiver. Thus Wieferich proved that the theorem holds for odd prime values of $n$, and values of $x$, $y$, $z$, not divisible by $n$, unless $2^{n-1}-1$ is a multiple of $n^2$.

One old conjecture has been definitely disposed of. Mersenne asserted that $2^n-1$, where $n$ is a prime not exceeding 257, is prime when, and only when, $n=1$, 2, 3, 5, 7, 13, 17, 19, 31, 67, 127, 257. This statement contains at least four errors, relating to the values 61, 67, 89, 107; and it need no longer be taken seriously.

AUTHORITIES.—An indispensable work for the serious student of higher arithmetic (on any of its sides) is L. E. Dickson, *History of the Theory of Numbers*, 1920–1. This work is not, however, specially concerned with the analytic theory.

For general accounts of the theory of primes see *Encycl. des Sc. Math.* i. 17 ("Propositions transcendantes de la théorie des nombres," by J. Hadamard and E. Maillet: the article by P. Bachmann in the first German edition is inadequate, but the third edition, in preparation in 1921, was to include an account of the theory, as it stands to-day, by H. Cramer); E. Landau, *Handbuch der Lehre von der Verteilung der Primzahlen* (1909), and *Einführung in die elementare und analytische Theorie der algebraischen Zahlen* (1918).

For the additive theory see P. A. MacMahon, *Combinatory Analysis* (1915–6), and *An Introduction to Combinatory Analysis* (1921); P. Bachmann, *Niedere Zahlentheorie*, II. (*Additive Zahlentheorie*) (1910); G. H. Hardy, *Some Famous Problems of the Theory of Numbers* (1920).

For Fermat's last problem see P. Bachmann, *Das Fermatproblem* (1917); L. J. Mordell, *Four Lectures on Fermat's Last Problem* (1921). Comparatively little of recent work is accessible in a connected form, and the study of the original memoirs is indispensable.

(G. H. H.)

## (3.) THEORY OF SERIES

The most striking modern developments in the theory of series (*see* 24.668; 10.753; 12.956) have also been suggested by the development of the theory of functions.

The theory of functions of a real variable has been revolutionized by the ideas of E. Borel and H. Lebesgue, and this revolution has inspired a corresponding revolution in the theory of Fourier's series and "series of orthogonal functions" generally.

A system of functions $\phi_m(x)$ $(m=1, 2, 3, \ldots)$ is said to be *orthogonal* if $\int_a^b \phi_m(x)\phi_n(x)dx=0 (m\neq n)$ . . . (1).

The simplest examples are obtained by taking $\phi_m(x)$ to be $\cos mx$ or $\sin mx$ and the interval $(a, b)$ to be $(0, 2\pi)$; or $\phi_m(x)$ to be Legendre's polynomial $P_m(x)$ and $(a, b)$ to be $(-1, 1)$. There is then a simple procedure by which we may endeavour to expand an arbitrary function $f(x)$ in the form of a series $\Sigma a_m\phi_m(x)$, viz. by multiplying this series by $\phi_m(x)$ and integrating over the interval $(a, b)$: the formula thus suggested is

$$f(x)=\Sigma a_m\phi_m(x),\ a_m=\left(\int_a^b f(x)\phi_m(x)dx\right)\Big/\left(\int_a^b \phi^2_m(x)dx\right) \quad . \ . \ . \ (2).$$

A more accurate analysis of this procedure raises a multitude of profoundly interesting and difficult questions. On the one hand we may start from a series with arbitrary coefficients $a_m$, and inquire whether there exists a function which stands to it in the relation expressed by the equation (2). In particular, given a trigonometrical series $\Sigma a_m \cos mx$ or $\Sigma b_m \sin mx$ or, more generally, $\Sigma(a_m \cos mx+b_m \sin mx)$, with arbitrary coefficients, we may ask whether it is a Fourier's series, that is to say, whether there is a function $f(x)$ such that $a_m$ and $b_m$ are given by Fourier's integral formulae. On the other hand, we may start not from an arbitrary series but from an arbitrary function $f(x)$, form the coefficients ($a_m$ or $b_m$) by Fourier's formulae or the more general formulae (2), and then inquire whether the formal development thus obtained is convergent, and whether, if convergent, it represents the function $f(x)$ and so forth.

The problems thus raised are among the most difficult of modern mathematics; and a very cursory examination of them is enough to show that the methods of the older analysis are not sufficiently powerful for their solution. It is essential that we should enlarge our conceptions, on the one hand, by taking account of the modern generalizations of the notion of an integral, and, on the other, by adopting a broader view as to what is meant by the "sum" of an infinite series.

The modern theory of functions of a complex variable (*see* 11.301) points to the same conclusion. A function $f(z)$ of the complex variable $z$, regular for $z=z_0$, is defined throughout a certain circle whose centre is $z_0$ by a power-series $\Sigma a_n (z-z_0)^n$; but the region of existence of the function is very generally more extensive than the circle of convergence of the series; and this fact has led, during the last generation, to a mass of work on the problem of "analytic continuation." This problem is that of discovering analytic representations of the function, whether by integrals, or by continued fractions, or by series of a different form, which are valid throughout a wider region than that in which it is represented by the original power series. Here also we are confronted by the need for a scientific theory of divergent series.

There are passages in the older analysts (*e.g.* in L. Euler), which suggest a half-conscious anticipation of modern ideas. But it is roughly true to say that they did not concern themselves with the precise meaning of the infinite series of which they made such effective use. A. L. Cauchy and N. H. Abel were the first to give a precise definition of the "sum" of a series $a_0+a_1+a_2+\ldots$ or $\Sigma a_n$, viz. as the limit of $s_n=a_0+a_1+\ldots+a_n$ when $n$ tends to infinity ($n\to\infty$). Such a series as $1-1+1-\ldots$ has then *no* sum, for $s_n$ is alternately 1 and 0; and it was the tendency, for many years after Cauchy and Abel, to banish such series from analysis entirely. A school of mathematicians survived, among whom one may cite A. de Morgan, who viewed this tendency with obvious discontent, but there was no escape from the conclusion that the followers of Cauchy and Abel were right. It is impossible to say "the sum of $\Sigma a_n$ is so-and-so" except after framing an accurate definition of "sum"; the definition of Cauchy and Abel was the only definition; and, until some new and wider definition was offered, that was the end of the matter.

We may define the meaning of a mathematical word or symbol as we please, provided only that the definition is free from contradiction. Given a sequence of numbers $a_1, a_2, \ldots$ we may associate with the sequence a number $s$ in any manner that we please, and we may say, if we like, that $s$ is the "sum" of the series. We might say, for instance, that the "sum" of every infinite series is, by definition, zero. This definition would be perfectly legitimate; but futile, because it would reduce all equations involving infinite series to the trivial form $0=0$; and confusing, because it would conflict with Cauchy's definition. Cauchy's definition is only one among many, but it is admittedly the most important, and a new definition is only likely to be of value if it is consistent with the standard definition. It must satisfy what is called the *condition of consistency;* it must apply to all convergent series, and give a "sum" equal to their sum in the ordinary sense. Its value for analysis will then be measured by the extent and importance of the class of non-convergent series to which it attributes a "sum."

The simplest and most important of the definitions which have been given is that of the "first arithmetic mean." Suppose that $s_n=a_0+a_1+\ldots+a_n$ and $\sigma_n=(s_0+s_1+\ldots+s_n)/(n+1)$, the arithmetic mean of the first $n+1$ values of $s_n$. If $s_n$ tends to a limit, $\sigma_n$ tends to a limit also, and the two limits are the same; but $\sigma_n$ may tend to a limit when $s_n$ does not. For example, if $a_n=(-1)^n$, $s_{2n}=1$ and $s_{2n+1}=0$, and $s_n$ does not tend to a limit; but $\sigma_n$ tends to the limit $\frac{1}{2}$. If now we agree to call the limit of $\sigma_n$, whenever it exists, the "sum" of the series $\Sigma a_n$, our new definition is in perfect accord with Cauchy's definition, but is applicable to an extensive class of series for which Cauchy's definition fails. It therefore fulfils the conditions required for a theory of divergent series.

The most striking illustration of the importance of these ideas is to be found in the theory of Fourier's series (*see* 10.753). The Fourier's series of a *continuous* function $f(x)$ is not necessarily convergent; further conditions on $f(x)$, of a much more artificial character, are required to insure convergence. It was, however, shown by L. Fejér that the Fourier series of any continuous function is "summable" by the procedure indicated above; that is to say, that the arithmetic mean $\sigma_n$ tends to a limit equal to the value of the function; and this fundamental result has been the starting point of a mass of modern research.

Another important definition attributes to the series as "sum" the value of the limit of the power series $\Sigma a_n x^n$ when $x$ tends to 1 through positive values less than 1. A third (of particular importance in complex function theory) was advanced by Borel; and all of these definitions have given birth to a multitude of still more general definitions.

AUTHORITIES.—For the general theory of divergent series *see* E. Borel, *Leçons sur les séries divergentes* (1901); T. J. I'A. Bromwich, *Introduction to the Theory of Infinite Series*, ch. x. (1908); G. H. Hardy and M. Riesz, *The General Theory of Dirichlet's Series* (1915). For the theory of Fourier's series, H. Lebesgue, *Leçons sur les séries trigonométriques* (1912); Ch. J. de la Vallée-Poussin, *Cours d'analyse infinitésimale*, 2nd ed., vol. ii. (1916); E. H. Hobson, *The Theory of Functions of a Real Variable* (1907, 2nd ed. in course of publication in 1921). The general theory of series of orthogonal functions is, for the most part, still only to be read in the original memoirs, or in works on the theory of integral equations. (G. H. H.)

## (4.) THEORY OF FUNCTIONS

The theory of functions (*see* 11.301, 14.53) has two great branches, the real and the complex theories. Recent advances in the complex theory, important as they are, have been of too

technical a character for rapid summary. The real theory, on the other hand, has been remodelled from its foundations. The older form of the theory was cumbrous and unattractive. The modern theory has the aesthetic character required of a first-rate mathematical science, and its development has been perhaps the most striking achievement of modern analysis.

1. *Sets of Points.*—The theory of functions of a real variable is based upon the theory of aggregates (*see* 19.847–850) and in particular the theory of "sets of points." A set of points $\zeta$ is an aggregate of real numbers $x$, such as the aggregate of rational numbers, or of irrational numbers, in the interval (0, 1). A number $\xi$ is said to be a "limit point" (*Häufungstelle*) of $\zeta$ if every "neighbourhood" of $\xi$, that is to say every interval $(\xi-\epsilon, \xi+\epsilon)$ including $\xi$, contains points of $\zeta$ other than $\xi$ itself. A limit point of $\zeta$ may or may not belong itself to $\zeta$. Thus every number of (0, 1), rational or irrational, is a limit point of the set $\zeta$ of rationals of (0, 1). If every limit point of $\zeta$ belongs to $\zeta$, $\zeta$ is *closed*. If every point of $\zeta$ is a limit point, $\zeta$ is *compact* or *dense*. A set which is both closed and compact is *perfect*. In particular, the continuum, the aggregate of all real numbers, is perfect: this is the first and most striking stage in G. Cantor's mathematical analysis of the continuum.

An idea of dominating importance in the theory of functions is that of the *content* or *measure* of a set of points. Suppose, for simplicity, that the set $\zeta$ in question is contained in (0, 1). Then Cantor defined the content of $\zeta$ as follows:—Divide (0, 1) in any manner into a *finite* number of intervals $\delta_i$ and these intervals $\delta$ into two classes $\delta_1$ and $\delta_2$, according as they do or do not include points of $\zeta$; and let $c(\delta)$ be the sum of the lengths of the intervals $\delta_1$. Then the *content* of $\zeta$ is the limit of $c(\delta)$ when the intervals $\delta$ tend to zero, if this limit should exist.

There is a striking defect in this definition, the full implications of which were first perceived by E. Borel. *The content of the sum of two sets is not generally the sum of their contents.* Thus the rationals of (0, 1) have content 1 (since every $\delta$ is obviously a $\delta_1$), and likewise the irrationals. The sum of the contents is 2, whereas the content of the sum is 1. The rationals of (0,1) cannot be included in a finite set of intervals whose aggregate length is less than 1. If we abandon the restriction that the set of intervals must be *finite*, the situation is completely changed. Thus Borel observed that we may include the rational $p/q$ in the interval $\left(\frac{p}{q}-\frac{\epsilon}{q^2}, \frac{p}{q}+\frac{\epsilon}{q^2}\right)$, and that the sum of all these intervals may be made as small as we please by choice of $\epsilon$; and this simple remark has revolutionized the theory of functions. The first step was to frame a satisfactory definition of *measure*, and this concept, which has entirely superseded Cantor's "content," is now defined as follows. We consider sets $\zeta$ included in (0, 1). Let $\zeta$ be enclosed, *in any manner whatsoever*, in a system of $\sigma$ of intervals $\delta$; let $m(\sigma)$ be the sum of the intervals of $\sigma$; and let $m_*$ be the lower bound (or "inferior limit") of the aggregate of values of $m(\sigma)$. Then $m_*$ is the *exterior measure* of $\zeta$. The *interior measure* $m_i$ is $1-m'_*$, where $m'_*$ is the exterior measure of $\zeta$, the set complementary to $\zeta$, *i.e.* the set of points of (0,1) which do not belong to $\zeta$. If $m_*=m_i$, the set $\zeta$ is *measurable*, and its measure is $m$, the common value of $m_*$ and $m_i$. This definition (due to H. Lebesgue) is of extreme generality, and no example of a non-measurable set is known.

Measure, thus defined, has the properties which measure ought to have, but which Cantor's content lacked. In particular the sum of two mutually exclusive and measurable sets is measurable, and its measure is the sum of the measures of the component sets. The measure of any enumerable set, and in particular of the rationals, is zero. The definition may be extended to sets in space of any number of dimensions.

2. *Integration.*—The new theory of measure has led to new theories of integration, in the light of which the older theories are of historical or didactic interest only. The most important of these theories are due to H. Lebesgue and W. H. Young.

(*a*) Lebesgue's definition of an integral is as follows. A function $f(x)$, defined in an interval $(a,b)$, is *measurable* if the set of points S (A) for which $f>A$ is measurable for every $A$. All known functions are measurable. We now suppose that $f$ is bounded, so that (say) $h<f<H$, and we divide up the interval $(h, H)$ into a finite number of intervals $(l_i, l_{i+1}$ or $\delta_i$. It is this subdivision of the range of variation of $f(x)$, instead of (as in the older theory) that of $x$, that is characteristic of Lebesgue's procedure. The set of points for which $(l_i \leqq f<l_{i+1})$ is measurable. If we denote its measure by $m_i$, write $J=\Sigma l_i m_i$ and suppose that the intervals $\delta_i$ tend to zero, then J tends to a limit I, and we write:

$$I=\int_a^b f(x)dx.$$

The integral so defined is a *bona-fide* generalization of the integral of Riemann, for it exists whenever Riemann's integral exists and agrees with it in value. But it is far more general: thus the function $f(x)$ which is unity when $x$ is a rational of (0,1), and zero otherwise, has no Riemann integral, but has a Lebesgue integral equal to zero. The definition is capable of many-sided generalization, to unbounded functions, and functions of many variables; it throws entirely new light on the relations between integration and differentiation; and it has proved itself adapted for a mass of analytical applications of the most far-reaching importance, in particular in the theory of Fourier's series and the theory of integral equations.

(*b*) A different definition was proposed by W. H. Young. He adheres to a subdivision of the range of variation $(a,b)$ of the independent variable; but, instead of dividing it into a finite number of intervals, divides it into a finite or infinite number of measurable sets. This procedure leads to results roughly equivalent to those of Lebesgue's theory; but it is somewhat more general; and is certainly a more natural development of the older theory of measure.

3. *Geometrical Applications.*—Those new theories have led inevitably to a searching reëxamination of the concepts of "curve," "surface," "length," "area," and so forth, which were generally accepted without question by the older analysts on the supposed evidence of geometrical intuition. This unreflective attitude has now been abandoned, and it is recognized that analysis is in no sense dependent upon geometry. The notion of a *curve* was first made precise by C. Jordan. A curve is a set of points $(x,y)$, that is an aggregate of pairs of real numbers $x$, $y$ where $x$ and $y$ are functions of a single variable $t$, subject to appropriate restrictions. A simple closed continuous curve is a curve for which (1) $x=x(t)$ and $y=y(t)$ are continuous for $t_1 \leqq t \leqq t_2$, (2) $x(t_2)=x(t_1)$ and $y(t_2)=y(t_1)$ and (3) it is false that $x(t')=x(t'')$ and $y(t')=y(t'')$ for any pair of values $t'$, $t''$ other than $t_1$, $t_2$. A fundamental theorem, due in substance to Jordan, asserts that such a curve C divides the plane into two "regions" D and D′ separated by the curve. Two points which lie in the same region can be connected by a continuous curve which has no point in common with C; but points which lie in different regions cannot be thus connected. We thus define the *inside* and *outside* of a closed curve in strictly analytical terms. A similar account has been given of the concepts of *area* and *length*. In particular the simple closed continuous curve C has both an area and a length if $x(t)$ and $y(t)$ are functions of bounded (or limited) variation.

AUTHORITIES.—More or less complete accounts of the modern theories will be found in: E. W. Hobson, *The Theory of Functions of a Real Variable* (ed. 2, vol. i., 1921); Ch. J. de la Vallée Poussin, *Cours d'analyse infinitésimale* (1909, 1912) and *Intégrales de Lebesgue, etc.* (1916). See also E. Borel, *Leçons sur la théorie des fonctions* (ed. 2, 1914), and *Leçons sur les fonctions de variables réelles* (1905); H. Lebesgue, *Leçons sur l'intégration* (1904) and *Leçons sur les séries trigonométriques* (1906); C. Caratheodory, *Vorlesungen über reelle Funktionen* (1918); H. Hahn, *Theorie der reellen Funktionen* (1921).

4. *Integral Equations.*—Among the remaining developments of modern analysis, perhaps the most remarkable are in the theory of integral equations. The typical integral equation is

$$f(x)=\int_a^b K(x,t)\phi(t)\,dt \qquad (1)$$

where $f(x)$ and $K(x,t)$ are given and the unknown function $\phi(t)$ is to be determined. This equation is called an integral equation of the first kind; but it has been found that equations of the form

$$\phi(x)=f(x)+\lambda\int_a^b K(x,t)\phi(t)\,dt \qquad (2)$$

known as equations of the second kind, are better adapted for the foundation of a general theory. It was shown by I. Fredholm that, if $f$ and K satisfy certain conditions, there is in general one and only one continuous solution $\phi(t)$; the exceptions arise when $\lambda$ is a zero of a certain transcendental function $D(\lambda)$. When $\lambda$ has one of these exceptional values, the equation

$$\phi(x)=\lambda\int_a^b K(x,t)\phi(t)\,dt$$

has a continuous solution other than the obvious solution $\phi(t)=0$, otherwise this is the only solution. The theory has been widely developed by Fredholm, D. Hilbert, V. Volterra and other writers.

Kneser, *Die Integralgleichungen und ihre Anwendungen in der Mathematischen Physik* (1911); and the third volume of E. Goursat's *Cours d'Analyse* (ed. 2, 1915). (G. H. H.)

### (5.) GEOMETRY

General remarks will be offered here in regard to two aspects of geometry (*see* 11.675) which may be held to be of contemporary interest, under the headings (*a*) Foundations of geometry; (*b*) Theory of classes of surfaces. Under the former heading it is not intended to discuss in detail the so-called Axioms of Geometry, for which the reader may be referred to the article with that title (*see* 11.730), but only to advert in general terms to questions which have indirectly been much in evidence of late in connexion with Einstein's theory of Relativity (*see* RELATIVITY). Under the second heading is included a quite technical theory, which now has great importance and a developing character.

(*a*) *Foundations of Geometry.*—The usual history of the development of the ideas of a student of geometry to-day is somewhat as follows. After a more or less prolonged (and highly desirable) course of experimental geometry, very largely (and undesirably) limited to a plane, in which a line is a mark made on paper, and a straight line is a mark which agrees with a physical object (a ruler), the student passes through a course in which he is shown that there is a logical connexion between the geometrical conceptions his experience may have led him to form. At first, and for a long time, often permanently, lines and circles are regarded as objects of perception and, for instance, there is no hesitation in accepting the idea of two lines being in the same direction, and it appears intuitive that two points must have a certain distance, a result of familiarity with the rigid bodies which the student has had put before him. This teaching, after a certain knowledge has been obtained of the detailed relations of circles and lines, often painfully acquired and difficult to remember, is continued, on the same plan, for the so-called geometrical properties of conic sections, though these are apt to appear at first as much less concrete than circles. After this, as soon as some facility with algebraical computation is acquired, the student learns that a straight line has an *equation*, and that, *e.g.* the common points of two circles depend on the solution of a quadratic equation, while the common points of two conics depend on a quartic equation. If his instruction is pursued far enough, he learns, with the expenditure of much time and energy, a vast number of algebraical devices, and is now, if apt in using them, capable of proving algebraically almost any question that his usual examinations are likely to require of him. For his further efficiency to this end he is probably taught towards the end of his career something about harmonic relations, about homography, and about projections. In particular, for example, he may be taught that the equations which give the foci of a conic are obtainable by applying the analytical conditions for a circle to the equation of the pair of tangents to the conic from any point. If he is fortunate it may be pointed out to him, near the end of his laborious drilling in detail, that a circle behaves as if it were a conic with two definite (albeit imaginary) points; and if he must in any case know the properties of conics he may, for economy of memory, seize hold of this remark, and come also to a geometrical description of the property of foci just referred to—and pursuing this course, if circumstances allow, he may finally reach a framework of hypothetical constructions including the so-called circular points and the circle at infinity, from which, looking back, as from a hill-top, he sees the whole country of geometrical fact, with which he has so laboriously become acquainted, shrink into a landscape dominated by very few main routes. He may now be at the stage of the third year university student. With continued consideration he may be led finally, even if only with the purpose of summarizing his geometrical outlook in the fewest possible ideas, to regard as working hypotheses such as the following: (*a*) there is no fundamental difference between points at infinity and those not at infinity; (*b*) there is no difference in reality between real and imaginary points; (*c*) there is no gain but great loss in refusing to consider space of more than three dimensions; (*d*) distance, as a fundamental conception, is unnecessary. And with these will come a recognition that the so-called non-Euclidian geometries are, logically, prior to the Euclidian geometry.

Leaving aside now the tempting pedagogic question of whether he has been justly treated in being so long denied the synthesis which, if he could have appreciated it, would so much have lightened his task of becoming familiar with the details, we remark that he finally works with a conceptual scheme, which includes the perceptual experiences by which it has been suggested—but discards many ideas which at earlier stages his perceptions seemed to suggest as necessary. For instance, the points of a line are not now in (linear) order, and lines have lost their straightness, the lines of threefold space being for many purposes better regarded as points of a quadric in five dimensions. Questions then arise such as: Is geometry unique in thus replacing the first crude ideas of physical experience by a conceptual scheme of entities, whose properties are determined logically, not from a set of *definitions* which tell us what these entities are, but from a set of fundamental propositions or statements of relations between them? And connected therewith, are the ideal entities of such a conceptual scheme less *real* than those, for example, which the physicist employs, say the aether, or electrons, to explain his conceptions? May the statement that distance is not necessary as a fundamental conception be fairly replaced by the statement that distance in the abstract is an illusion? It would seem that the difference is one only of the degree of abstractness of the conceptual scheme employed. We may in geometry itself have different levels of abstractness; for example, we may in the first instance regard the points of a line as conforming to our idea of an abstract order of such a kind that the so-called Dedekind's axiom is applicable, although finally, when we allow the so-called imaginary points, we discard this notion of order and use the word line in a still more abstract sense. It would seem that every science as it advances in comprehensiveness must similarly evolve for itself a conceptual scheme of ideal entities; and that even in strict logic, no proposition can be asserted to be true or false except in reference to entities whose fundamental relations are made explicit.

Such questions as these arise when it is assumed that it ought to be possible to ascertain by observation whether the world is finite, or still more whether space (in the abstract) is Euclidian or non-Euclidian. If the attitude which has been suggested is sound, the most that can be done is to inquire what would be the modifications in our statements of perceptual regularity which would follow if we adopted a particular scheme of conceptions in regard to the extent of the world, or the character of space.

Of such conceptions, those which have reference to a method of measurement are of fundamental importance. And if measurement is possible at all, it must presumably be based upon a scheme for assigning identification numbers to the points of bodies which are to be measured. This is not the same as assigning numbers to points of space, nor even if this could be done would the method of measurement be determined uniquely thereby. A way of assigning identification numbers to the points of a figure must be conditioned (*a*) by the fundamental theorems of incidence of the elements of the figure (as that a line is determined by two points, or that two planes meet in a line); (*b*) by the nature of the numbers to be used (whether they allow commutative multiplication for example); (*c*) by the freedom of the assignment, that is the number of points of the figure for which the corresponding numbers may be assigned arbitrarily, the numbers belonging to any other point being then determinate; (*d*) which is in fact included under (*a*), by the character of the "infinity" of the figure (as whether the space of the figure is open or closed); and even then (*e*) it appears to be necessary to assume one or more definite limiting theorems of incidence. In the way which has been studied most in detail, as being that which is most naturally suggested by the Euclidian scheme in which geometrical thought has developed, the numbers being taken to be those of ordinary arithmetic, it is possible to assume arbitrarily the numbers for three points of a line, so long as this is considered by itself, the numbers of four points of a plane regarded as isolated, and the numbers of five points of a three-dimensional space; this space is regarded as closed, the numbers belonging to a point are regarded as ratios of numbers, and infinite values of numbers are thereby excluded from consideration—and the assumption is made that four lines of which no two intersect have two common transversals. It is shown that the introduction of this assumption is equivalent (other things being equal) to assuming that the numbers used are commutative in multiplication. The number space of Descartes, in which each point is represented by three ordinary numbers, one or more of which may be infinite, may be regarded as a particular case of the so-called projective space thus described.

In his famous *Habilitationsschrift* (1854), when 28 years old, B. Riemann considered a Cartesian space in which each point is specified not by three but by $n$ numbers or coördinates, and proposed to measure the distance between two neighbouring points by means of a quadratic function of the small differences of their corresponding coördinates. He remarked then that such a space has not necessarily any rigid bodies capable of movement without change of linear dimensions. For this to be possible it is necessary and sufficient that certain functions of the coefficients in the quadratic form and their differential coefficients should be constant. The number of these functions is $\frac{1}{12}n^2(n^2-1)$; for instance for $n=2$, this number is 1, and for $n=3$, it is 6. When these conditions are satisfied the space is said to be of constant curvature. But it is to be remarked that a Cartesian space of $n$ dimensions, such as that considered by Riemann, is in reversible, point-to-point correspondence with a quadratic manifold (also of $n$ dimensions), in a projective space of $n+1$ dimensions. In such a space of $n+1$ dimensions, as was first remarked by Cayley, we can set up a measurement of distance between any two points by taking, quite arbitrarily, a quadric manifold of reference. It is then the case that Riemann's definition of distance, when his space is of constant curvature, and allow srigid bodies capable of movement, is so obtainable, after Cayley's manner.

These details appear to bring out very clearly that even when the difficult step has been made of passing from the descriptive properties of a geometrical figure to the assignment of coördinates, it is a further step of much artificiality to introduce a measure of the distance between any two points.

In recent years, under the stimulus of A. Einstein, H. Minkowski, H. Weyl and others, Riemann's dearest dream of a uniform formulation of all phenomena of physics, has, it would seem, been brought appreciably nearer to realization, in what is known as a Theory of Relativity. An event, occurring in a definite place at a definite time, is regarded as depending on three coördinates for its position, and one for its time, and these four together are spoken of as its coördinates in a Cartesian space of four dimensions. As formulated by Einstein, there is an interval between two neighbouring events, given by a quadratic in the differences of their corresponding coördinates; this quadratic will then have ten coefficients. It can be shown that there exist functions of these coefficients and of their derivatives in regard to the point coördinates, which are unchanged in value if calculated for the quadratic form into which the given one is transformed by any transformation of the coördinates; for instance, the 20 functions which, as has been stated, arise in the consideration of what is called the curvature, are such functions. It is clear that the vanishing of such an invariantive function expresses a fact which is not altered by any simplification that may be possible in the form of the quadratic expression; for instance if the 20 functions above referred to all vanish the quadratic expression has a form the same as in Cartesian Euclidian geometry; and if they are all equal to the same

quantity independent of coördinates, the quadratic expression has the form considered by Riemann. In Riemann's theory, following Gauss, account is taken of curves, called geodesics, which satisfy the condition that the integral $\int ds$, taken along with such a curve, shall be stationary according to the ordinary rules of Lagrange's *Calculus of Variations*, where $ds$ is the square root of the quadratic expression referred to. Einstein's suggestion is that the path of a particle under the influence of what we call gravitating masses may be represented as such a geodesic, provided the coefficients in the quadratic form are chosen to depend suitably upon these masses; and this has proved capable of verification in the case of the planet Mercury, and in the case of a ray of light passing near to the Sun. An analogous suggestion has led Weyl not only to the equations belonging to the theory of gravitation, but also to those which express the phenomena of electromagnetism (and light). And it is very interesting from our present point of view to see the character of the modifications which Weyl has been led to make in Einstein's mathematical formulation in order to attain this end. For our present purpose we may state this in a twofold manner without entering into the logical connexions. In the first place, in Weyl's theory, instead of the quadratic form $ds^2$ being regarded as definite for two specified neighbouring events, a product $\epsilon\phi s^2$ is regarded as definite, where $\phi$ is a function variable from point to point, whose derivatives in regard to the coördinates are utilized to represent electromagnetic phenomena. As Weyl writes (*Math. Zeitschrift*, II. p. 397, 1918), "Riemann machte die . . . Annahme, dass sich Linienelemente nicht nur an derselben Stelle, sondern auch an zwei endlich entfernten Stellen ihrer Länge nach miteinander vergleichen lassen. Die Möglichkeit einer solchen ferngeometrischen Vergleichung kann aber . . . nicht zugestanden werden." This is precisely in the spirit which has moved geometers increasingly since the publication of G. K. C. von Staudt's *Geometrie der Lage* (1847). It introduces however evidently a wide arbitrariness, which Weyl limits by adopting as a datum the possibility of the translation of a vector given at one point to another neighbouring point *without change of direction*. This conception, adopted from T. Levi-Civita (*see* Levi-Civita, *Palermo Rendiconti*, XLII., 1917, pp. 173–205, and F. Severi, *ibid.*, p. 254), is as follows:—The two elements of direction defined by (*a*) the vector at the first point P and (*b*) the displacement from P to the neighbouring point P', define a family of geodesic directions through P, forming a surface; the parallel vector at P' is that whose direction *on this surface* makes with the direction PP' the same angle as that made by the vector at P. Evidently the assumption of the possibility of this determination of unchanged direction is fraught with large consequences or conditions. A suggestion subsequent to Weyl's (A. S. Eddington, *Proc. Roy. Soc.* XCIX., 1921, pp. 104–122), begins with Levi-Civita's differential equations for parallel displacement of a vector, but working backwards towards the quadratic differential form leads to a generalization of Weyl's formulation.

So much of detail in regard to these remarkable contemporary speculations seems necessary in order to compare the geometrical aspects with those of older conceptions. In the so-called space of Einstein, still less in Weyl's space, there exist neither bodies, nor movement; and what are the fundamental geometrical conditions assumed prior to the establishment of the system of coördinates is as yet undetermined. The latter fact, which is equally true of any Cartesian space, may provisionally be evaded by regarding the space as being in point to point correspondence with a quadric manifold in a projective space of five dimensions; the former fact, which relates to the consideration of a quadratic differential expression, is most probably, if it proves finally to be possible to put the phenomena of physics into exact correspondence with geometrical considerations, suggestive of a physical theory which, given some fundamental relations of experience, shall be developed not by computation, but by descriptive methods. For the aim of geometry, towards which since von Staudt's time, much progress has been made, is such a descriptive conception of the relations of figures in space as may render computation unnecessary.

(*b*) *General Theory of Surfaces.*—The older theory of circles and conics, or of rational curves in general, as also the theory of quadric surfaces, of cubic surfaces or of rational surfaces in general, can be placed in (1, 1) correspondence with the geometry of lines, or of the planes, respectively; it deals ultimately with linear equations when viewed analytically. A consideration of cubic curves on a plane, or of the curve of intersection of two quadric surfaces, soon shows that these do not depend upon linear equations ultimately—or more precisely that the points of a plane cubic curve cannot be put into (1, 1) correspondence with the points of a line. And it further appears that a quartic curve in a plane is again of a higher category, and cannot be put into (1, 1) correspondence with a cubic curve. This fact first emerges clearly in Abel's great paper on the integrals of algebraic functions. The general theory of the so-called Higher Curves was then historically subsequent to the theory of algebraic functions and the integrals of these; though, when this theory had received a sufficient development, it proved possible to elaborate a descriptive theory of these curves embodying the results obtained by the earlier analytical methods. In geometry, entities which can be put into exact (1, 1) correspondence are equivalent for geometrical purposes, and conversely, for purposes of a general theory, it is vital to know whether two entities have this equivalence or not. It is one of the most important recent developments of geometry to have made it clear that criteria can be given by which to determine whether two surfaces have this (1, 1) correspondence. And it is interesting to remark that historically the development in this case has been on similar lines to that by which the corresponding result was obtained for curves; in the first place, over many years, Picard developed the theory of algebraic integrals associated with surfaces on lines as far as possible analogous to those which had been followed in the case of curves, therein in part carrying out a suggestion due to Clebsch and Noether, though the integrals which have proved most effective hitherto were not those suggested by Clebsch; after this the geometrical aspect of the matter was investigated by Italian geometers, more especially Enriques, Castelnuovo and Severi, who have succeeded in surpassing, in beauty and generality, even the distinguished contributions of their own countrymen to the theory of curves. It is impossible indeed to convey to a nongeometrical reader any idea of the interval which separates the development of geometry in Italy to-day from the development reached in England.

The new theory is under the disadvantage that an appreciation of it is impossible without sympathy and acquaintance with the theory of algebraic functions and their integrals, and it may be some time before detailed applications of it become the common property of mathematicians. But it offers a limitless scope for new work, its importance cannot be doubted, and its permanence is assured.

BIBLIOGRAPHY.—For the questions suggested by the Einstein-Minkowski work, ample material arises in attempting to sift into logical coherence many of the current writings on Relativity. An ample bibliography of these concludes the work of Hermann Weyl, *Raum-Zeit-Materie, Vierte erweiterte Auflage, Berlin, 1921.* The English reader will find much stimulus to geometrical consideration in Eddington's volume, *Space, Time and Gravitation* (Cambridge, 1920); and should consult E. Cunningham's two fundamental volumes on *Relativity*, and A. A. Robb, *A Theory of Time and Space* (Cambridge, 1914).

Emile Picard's work is summarized in his book *Théorie des fonctions algébriques de deux variables indépendentes* (Paris, 1897–1906), which concludes with a summary by MM. Castelnuovo et Enriques (t. II., pp. 485–522) of the results obtained by the Italian geometers up to 1906. Subsequent progress is recorded (and scattered) in the various mathematical journals, mainly of Italy.

(H. F. BA.)

**MATHEWS, SIR CHARLES WILLIE** (1850–1920), English lawyer, was born in New York Oct. 16 1850, the son of the actress Mrs. Davenport, who became in 1857 the second wife of the comedian Charles James Mathews (*see* 17.887). The boy took his stepfather's name, and was sent to England to be educated at Eton. In 1868 he entered the chambers of Montagu Williams, the well-known criminal lawyer, as a pupil, and in 1872 was called to the bar. His rise was rapid, and he soon built up a wide connexion and became known as an extremely skilful cross-examiner. In 1886 he was made counsel to the Treasury, from 1893 to 1908 was recorder of Salisbury, and in 1908, on the retirement of Lord Desart, became director of public prosecutions. Mathews, who was knighted in 1907 and received the K.C.B. in 1911, was concerned in most of the important criminal cases and *causes célèbres* of his time, among them being the Colin Campbell divorce suit (1886), the trial of the Jameson raiders (1896), and the prosecution of Lynch for high treason (1903). He was also well known in the theatrical world, being a constant attendant at first nights, and was besides an excellent after-dinner speaker and all-round sportsman. He died in London June 6 1920.

**MATTEI, TITO** (1841–1914), Italian musician and composer, was born at Campobasso, near Naples, May 24 1841. He became at an early age a professor at the Santa Cecilia academy of music at Rome, and subsequently had several successful European tours as a pianist. In 1863 he finally settled in London, where he remained for the rest of his life. He composed several hundred songs and pianoforte pièces, many of which became very popular. He died in London March 30 1914.

**MATTER, CONSTITUTION OF** (*see* 17.891).—In the decade 1910–20 many important advances were made which gave much more definiteness and precision to our knowledge of the constitution of matter. The atomic theory of matter, which for long appeared to be of necessity unverifiable by direct experiment on account of the minuteness of the atom, received almost direct proof in a number of ways. Methods have been developed, for example, to detect the electrical effect of a single $\alpha$ particle from radium, and a single swift electron (*see* GASES, ELECTRICAL PROPERTIES OF).

The $\alpha$ particle has been shown to be a charged atom of helium

projected with high velocity; the number of $\alpha$ particles from a given quantity of radium have been counted, and the volume of helium which they produce has been measured. In this direct way it has been shown that about $2{\cdot}7\times10^{19}$ particles or atoms of helium are required to form one cubic centimetre of helium gas at normal pressure and temperature. Not only is it feasible to detect the effect of a single atom of matter in special circumstances but also to show the path of a swift $\alpha$ particle or electron through a gas. This has been made possible by the discovery of C. T. R. Wilson that under suitable conditions the charged ions produced in gases by $\alpha$ or $\beta$ rays become centres for the condensation of water vapours, and are thus rendered visible as the nuclei of visible drops of water. The photographs of these droplets show in a most striking way the track of the particle through the gas, and illustrate with extraordinary detail the main effects produced by the passage of ionizing radiations through gases.

The essential correctness of the kinetic theory of matter, which assumes that the molecules of matter are in vigorous but irregular motion, has been clearly demonstrated by the experiments of Perrin and others on the motion and equilibrium of small spheres of matter in suspension in fluids which show the Brownian movement. At the same time the atomic or discrete nature of electricity, which had been implicitly assumed in many theories, has received complete experimental verification, and the magnitude of this fundamental unit of charge has been measured with precision. The most accurate experiments on this subject have been made by Millikan by measuring the electric field required to support a small, charged droplet of oil or mercury. The charge on the drop was varied by ionizing the gas in its neighbourhood. In this way he has been able to show that the charge always varies by integral multiples of a fundamental unit. The charge given to a drop by friction or any other method is always an integral multiple of this unit charge. This fundamental unit is the same both for positive and negative electricity, and is numerically equal to the charge carried by the negative electron, the positive and negative ions produced in a gas by X rays, and also to the positive charge carried by the hydrogen atom in the electrolysis of water. The magnitude of this unit charge, combined with electrochemical data, gives a most reliable method of measuring a number of important and molecular magnitudes. The value of the fundamental unit of charge and thus the mass of the individual atoms of matter are now known with an accuracy of certainly within one per cent and possibly within one-tenth of one per cent. The data found by Millikan are given in the following table:—

| | |
|---|---|
| Fundamental unit of charge . | $e=4{\cdot}774\times10^{-10}$ electrostatic units |
| The Avogadro Constant, *i.e.* the number of molecules in one gramme molecule . . . | $N=6{\cdot}062\times10^{23}$ |
| The number of molecules per c.c. of any gas at 0° C. and 760 mms. | $n=2{\cdot}705\times10^{19}$ |
| Mass of hydrogen atom in grammes | $m=1{\cdot}662\times10^{-24}$ |

From these data the number of atoms in one gramme of any element can be determined. While the average distance apart of the atoms or molecules can at once be deduced, the actual dimensions of the molecules or sphere of action of the molecules can only be approximately estimated with the aid of other and much less precise data.

*Structure of the Atom.*—Since the proof that the negative electron of small mass is a constituent of all atoms of matter, there has been a vigorous attack on the fundamental problem of the structure of the atom. After passing through a number of phases the general ideas on this subject have crystallized into a fairly definite form, and it is now generally believed that the atom is composed of a massive positively charged nucleus of minute dimensions surrounded at a distance by a compensating distribution of negative electricity in the form of negative electrons. Since electricity is atomic the resultant positive charge on the nucleus must be an integral multiple $N$ of the fundamental unit of charge $e$ and is given by $Ne$. In order for the atom to be electrically neutral it must be surrounded by a distribution of $N$ negative electrons. The value of $N$ for each of the atoms is a fundamental constant, for on it depends the magnitude of the electric field surrounding the nucleus and the arrangement of the external electrons which in turn determine the main physical and chemical properties of the atom. The idea of the nuclear structure of atoms arose initially from a study of the scattering of $\alpha$ particles in their passage through matter. On account of its great energy of motion the charged $\alpha$ particle penetrates the structure of some of the atoms and comes under the influence of the intense repulsive field of the nucleus. Assuming that the law of force is that of the inverse square the $\alpha$ particle describes a hyperbolic path, and the angle of deflexion depends on the nearness of approach to the nucleus. From a close study of the scattering of $\alpha$ rays by Geiger and Marsden it was concluded that the number of $\alpha$ particles scattered through different angles was in close accord with the idea of the nucleus atom, while the actual number scattered through a given angle gave information on the magnitude of the charge carried by the nucleus. The preliminary experiments indicated that for the heavier atoms the value of $N$ was about half the atomic weight in terms of hydrogen. A notable advance was made by the fundamental experiments of Moseley on the X-ray spectra of the elements. He found that the X-ray spectrum was similar for all elements, and that the frequency of vibration of corresponding lines in the spectrum was proportional to the square of a number which varied by unity in passing from one element to the next. He concluded that the nuclear charge in fundamental units was equal to the atomic or ordinal number of the elements when arranged in increasing order of their atomic weights. On this view the lightest element, hydrogen, has a nuclear charge 1, helium 2, lithium 3, and so on up to the heaviest element, uranium, of ordinal number 92. This is a generalization of great importance and simplicity which has guided all subsequent work on the structure of atoms. The essential correctness of Moseley's conclusion has been directly verified in the case of a few representative elements by Chadwick by accurate measurement of the nuclear charge based on the scattering of $\alpha$ rays. Moseley showed that with few exceptions all values of the nuclear charge between 1 and 92 were represented by known elements. The missing elements were of ordinal numbers 43, 61 and 75, corresponding to positions in the Periodic Table where the existence of additional elements had been suspected. Moreover, when the atomic weight of the element in Mendeleef's classification was replaced by its ordinal number certain irregularities were removed. For example, the positions of argon and potassium, cobalt and nickel, iodine and tellurium were interchanged—a result in complete accord with their chemical properties (*see* CHEMISTRY).

It thus follows that the main physical and chemical properties of an element are defined by a whole number which represents both its nuclear charge in fundamental units and the number of external electrons. The atomic weight of an element is in a sense a secondary property, for, as we shall see, elements can exist of the same nuclear charge but of different atomic weights. The number and position of the external electrons, on which the ordinary chemical and physical properties of an atom depend, are defined by the nuclear charge. The mass of the atom which resides mainly in the nucleus exercises a subordinate effect on the external arrangement of the electrons.

*Isotopes.*—On Moseley's classification only 92 elements of ordinal numbers 1 to 92 are possible, assuming that uranium (92) is the last of the elements. We shall now briefly discuss some recent advances which clearly show that in some cases several elements can exist with the same nuclear charge but of different atomic masses. Information on this point was first obtained from a study of the radioactive bodies. It was early observed that a number of products which showed different radioactive properties were inseparable from one another by ordinary physical and chemical methods. For example, ionium and thorium, radium and mesothorium, radium D and lead cannot be separated from each other, and appear to be identical in chemical properties. Elements so closely alike in chemical properties were called "isotopes" by Soddy, since they appeared to occupy the same position in the periodic arrangement of the elements. Viewed from the standpoint of the nuclear theory isotopes are elements

of the same nuclear charge but of different atomic masses. As we have seen, the nuclear charge controls the ordinary physical and chemical properties of the atom, and the mass which resides almost entirely in the nucleus has only a second-order effect. On the other hand, the property of radioactivity depends on the structure and stability of the nucleus, which may be very different for atoms of the same resultant nuclear charge.

In the article on RADIOACTIVITY attention is drawn to the remarkably simple relation which exists between the chemical properties and radiations of the series of radioactive elements. With the aid of this relation we can at once write down the ordinal numbers and masses of the long series of elements which arise from the transformation of uranium, thorium and actinium, and can follow the origin of the numerous isotopes which arise. One of the most striking results of this generalization was the prediction that the end product of the uranium and thorium series should be an element of the same ordinal number as lead but of atomic masses 206 and 208 respectively, instead of the mass 207 found for ordinary lead. This result has been directly confirmed by atomic weight determinations of uranium-lead and thorium-lead, and was the first definite proof of the existence of isotopes of a non-radioactive element.

It seemed probable that in a similar way many of the ordinary elements might consist of a mixture of isotopes, *i.e.* elements with the same nuclear charge but different atomic masses. This has been confirmed in a number of cases chiefly by the work of Aston. The masses of the positively charged atoms present in the electric discharge in a vacuum tube are examined by bending the rays in a combined magnetic and electric field. In this way it was found that neon consisted of two isotopes of masses 20 and 22 and chlorine of isotopes of masses 35 and 37. The relative proportions of the two isotopes in chlorine was in good accord with that to be expected from the ordinary atomic weight of the mixture of isotopes, viz. 35.45.

This new method of analysis had, up to 1921, been employed only for a small number of the elements, but had yielded results of great interest. Some of the elements, like carbon, nitrogen and oxygen, give no isotopes, and are thus to be regarded as "pure" elements where the atoms have all the same mass and nuclear charge. Others, like chlorine, argon, krypton, and mercury, are composed of a mixture of two or more isotopes. In cases like krypton and mercury as many as six well-defined isotopes have been detected. As far as observation has gone the masses of all the isotopes are expressed by a whole number in terms of O = 16 with an accuracy of about 1 in 1,000. For example, the isotopes of neon are 20.00 and 22.00. This important conclusion, which has been verified in a number of cases, affords a strong indication that the masses of the parts composing the nucleus have a mass either of one or a multiple of one, and are not direct multiples of the mass of the hydrogen atom which is 1.008 where O = 16. The reason of this will be discussed later.

While the ordinary physical and chemical properties of isotopes are closely similar, it is to be expected that they should differ in all qualities which involve directly the mass of the atom, *e.g.* the coefficients of diffusion and specific heats. In a similar way second-order effect is to be expected in the rate of vibration of the external electrons, *i.e.* in the light spectrum of the element, and a small effect has been observed in several cases. The most obvious method of partial separation of isotopes is by the process of diffusion or evaporation. In this way a partial separation into light and heavy fractions has been shown in the case of neon, mercury, and chlorine. No evidence of the separation of isotopes in nature has been so far observed except in the case of uranium-lead and thorium-lead already referred to. It will be of great interest to test, for example, whether chlorine obtained from widely different sources shows any difference in the relative proportions of its component isotopes.

*Distribution of Electrons.*—We have seen that the atom is to be regarded as an electrical structure in which a positively charged nucleus is surrounded by a number of electrons. The magnitude of the nuclear charge and the number of the external electrons are known for each of the elements. In considering the distribution of the external electrons round the nucleus, we are at the outset faced by the great difficulty that no possible arrangement can be permanently stable on the basis of the classical dynamics. For example, an electron in motion round the nucleus must on the classical theory radiate energy and fall into the nucleus. To overcome this fundamental difficulty Bohr has introduced a conception based on the quantum theory, in which radiation only occurs in definite quanta. In this way it is possible to postulate the position of the electrons in the simpler atoms and to calculate their frequency of vibration. The theory of Bohr developed by Sommerfeld and others has achieved remarkable success in explaining many of the details of the spectra of hydrogen and helium both in electric and magnetic fields. Owing, however, to the great complexity of the possible modes of motion when three or more electrons are present, it is difficult to calculate the distribution of the electrons and their modes of vibration in the case of the more complex atoms.

A number of suggestions have been made as to the grouping of the electrons in the atom, notably by Kössel, Lewis, Langmuir and Sir J. J. Thomson, which have had a certain measure of success in offering an explanation of the periodic variation in the properties of the elements with atomic number and the methods of combination to form molecules. These theories, however, are for the most part descriptive and not quantitative in character. The whole problem of the distribution and motion of the electrons in a complex atom is a very difficult one. While definite progress had been made by 1921, much still remained to be done before we could hope to define with any certainty the position, motion and modes of vibration of the electrons for even the lighter and less complex elements.

*Structure of the Nucleus.*—While it is difficult to estimate the dimensions of atomic nuclei, the general evidence indicates that the nucleus of a heavy atom like uranium, if assumed spherical, has a radius of less than $10^{-11}$ cm. or less than 1/1000 of the radius of the external atom. No doubt the dimensions of a nucleus depend on its complexity and are much smaller for the lighter atoms. From experiments on the passage of $\alpha$ particles through hydrogen, it has been calculated that the dimensions of the helium nucleus of mass 4 is of the order $10^{-12}$ cm.

The most direct evidence on the constitution of the nucleus is derived from the study of the radioactive transformations. The disintegration of an atom is accompanied either by the expulsion of an $\alpha$ particle, *i.e.* in helium nucleus, or the release of a swift electron from the nucleus. This shows that the nucleus of the radioactive atoms contains both positively charged masses and negative electrons, and that the nuclear charge represents the resultant charge. It is natural to conclude that the helium nucleus of mass 4 is one of the secondary units which make up the structure of a complex nucleus. This is supported by the observation that the atomic mass of many atoms is expressed by $4n$ where $n$ is a whole number. It is clear, however, from the work of Aston on isotopes that, in addition to the helium nucleus, an element of mass 1 or integral multiple of 1 enters into the structure of all nuclei. This fundamental unit of structure has been named "proton," and its atomic mass is 1 or very nearly 1 in terms of O = 16. On this view the nuclei of all elements are made up of positively charged protons and electrons. The mass of the atom measures the number of protons in the nucleus. This is in a sense a return to the famous hypothesis of Prout in which all the atoms are supposed to be built up of hydrogen as the fundamental unit.

It seems clear that if a proton could be removed from an atomic nucleus it would prove to be the hydrogen nucleus carrying a unit positive charge. In fact, Rutherford and Chadwick have shown that the hydrogen nucleus can be liberated from certain atoms like nitrogen and aluminium by bombardment with swift $\alpha$ particles. It remains, however, to explain why the proton in a nucleus has a different mass from the free hydrogen nucleus. The latter has a mass 1.008 in terms of O = 16 while the proton in the nucleus has a mass unity, or nearly unity.

While the negative unit of electricity exists in the form of the electron of very small mass, no evidence has been obtained that

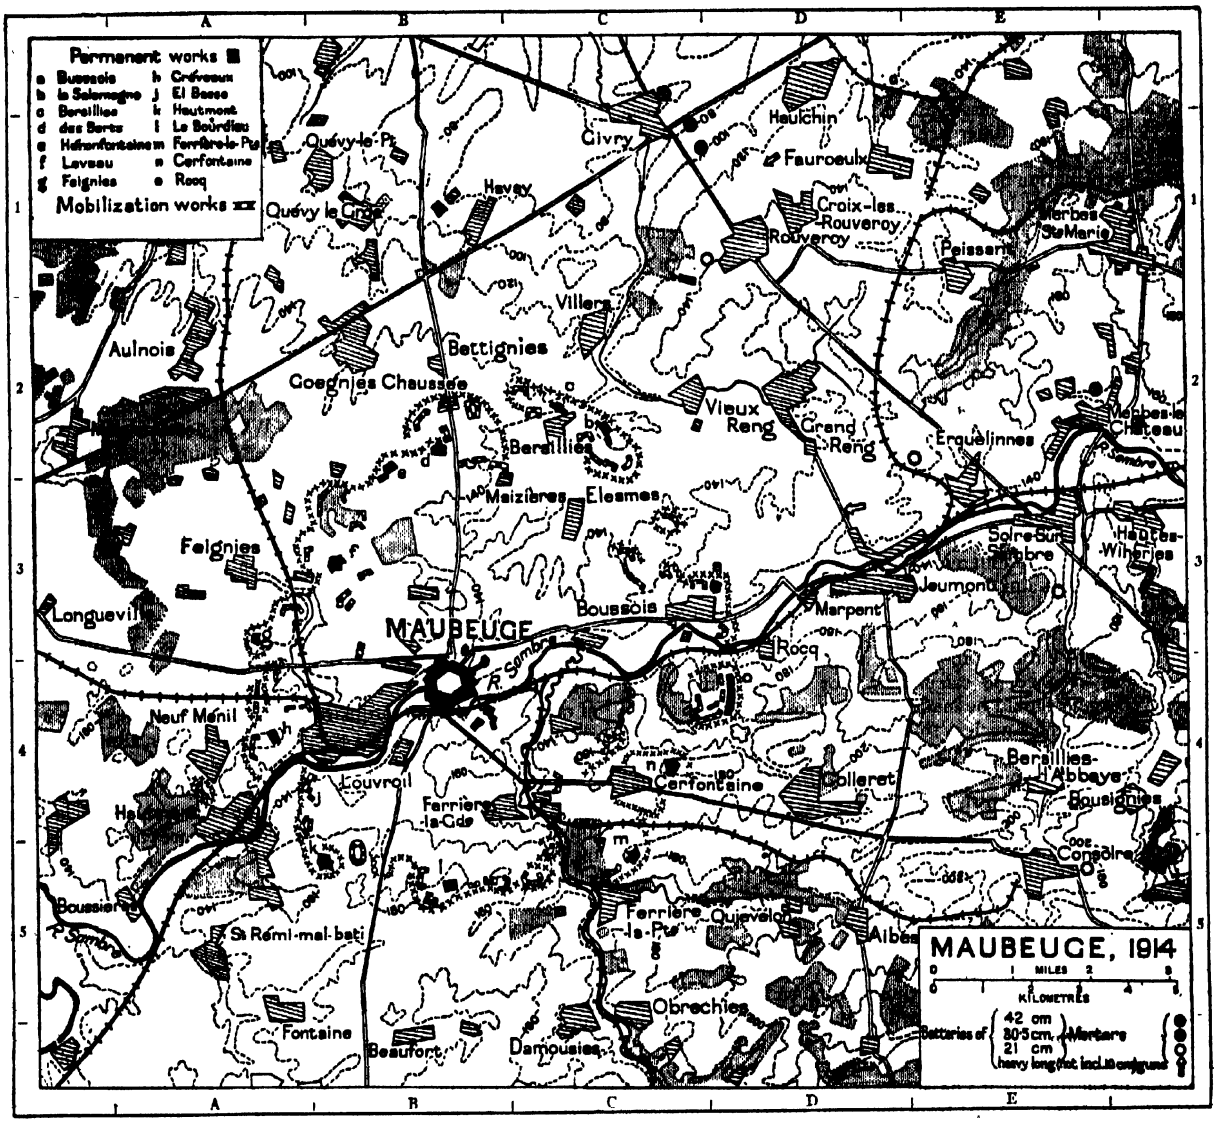
its counterpart, the positive electron of very small mass, exists. The unit of positive electricity has never been found to be associated with a mass less than that of the hydrogen atom. This has led to the view that the hydrogen nucleus is the *positive* electron, and that its mass is about 1,845 times that of the negative electron. This difference in mass between the units of positive and negative electricity appears to be fundamental, and offers an explanation of the asymmetrical distribution of positive and negative electricity in the structure of atoms.

Since the helium nucleus has a mass 4 and charge 2, it should be composed of four hydrogen nuclei and two electrons. Its mass, however, is less than that of four free hydrogen nuclei. Such a change of mass in the very close combinations of positive and negative nuclei is to be expected. According to the theory of relativity energy has mass, and the loss of mass $m$ of a system is numerically given by $E=mc^2$ where $E$ is the energy liberated and $c$ the velocity of light. On this view the combination of the positive and negative electrons to form the helium nucleus is accompanied by a large release of energy. From the difference between the mass of the helium nucleus and that of four hydrogen nuclei, it can readily be calculated that the helium nucleus is such a stable combination that an amount of energy corresponding to four or five $\alpha$ particles from radium would be required to dissociate it. The difference between the masses of the protons in the nucleus and free hydrogen nuclei is thus to be ascribed in general to the close packing of the positive and negative units composing the nucleus.

On the views outlined above the number of electrons in any nucleus can at once be calculated. For example, oxygen of nuclear charge 8 should be made up of 16 positive units and 8 electrons. For such a nucleus to hold together it seems clear that the forces between the charged units at such small distances must be different from that of the inverse square. While it has been experimentally shown that the law of the inverse square holds at any rate approximately close to the nucleus of a heavy atom like gold, this law breaks down in very close collisions of light atoms where the nuclei approach very close to each other. For example, it has been found that the number of hydrogen atoms which are set in swift motion when $\alpha$ particles pass through hydrogen is very different from that to be expected if the nuclei behave as point charges repelling each other according to the law of the inverse square. The experimental information at present available is too indefinite to hazard more than a guess as to the nature and magnitude of the forces that come into play when nuclei approach very close to one another, as they must do in the structure of the nucleus of a heavy atom.

*Stability of Atoms.*—Apart from the heavy radioactive elements which belong to a class by themselves, and two other elements—potassium and rubidium—which spontaneously emit swift electrons, the atoms of the ordinary elements appear to be very stable structures which cannot be broken up by ordinary chemical and physical agencies. Some experiments have suggested that possibly helium and hydrogen may be liberated by the passage of an electric discharge through gases, but on account of the presence of these elements in many materials it is difficult to prove definitely that they arise from artificial transformation. In considering the possibility of the disintegration of elements it should be borne in mind that the loss of one or more electrons from the outer electronic system has no permanent effect on the atom, for other electrons ultimately fall into the atom to fill their place. In order to produce a permanent transformation of the atom it appears necessary to remove a positively charged particle or an electron from the nucleus of the atom. This can only be effected by agencies which are able to penetrate the nucleus or to pass very close to its structure.

The $\alpha$ particle expelled from radium is one of the most concentrated sources of energy known to us, and on account of its speed should be able to penetrate the structure of the nuclei of many of the lighter atoms and still retain sufficient energy to disrupt the bonds that hold the parts of the nucleus together. In the case of an atom of high nuclear charge the $\alpha$ particle may lose so much of its energy in approaching the nucleus that it may be unable to effect its disintegration. It has been found that when $\alpha$ particles pass through hydrogen or any material containing combined hydrogen some of the particles pass so close to the hydrogen nucleus that they set it in swift motion. These swift hydrogen atoms can be detected by the scintillations they produce on a zinc-sulphide screen. This is purely a case of collisions of atomic nuclei, and the speed of the "H" atom set in motion can be calculated by the ordinary laws of mechanics. The maximum range or distance of penetration of such a particle is about four times that of the incident $\alpha$ particle.



In a similar way other nuclei must be set in swift motion by their collision with $\alpha$ particles, but it can be calculated that in most cases such nuclei are unable to travel as far as the $\alpha$ particle, and thus remain undetected amid the great number of incident $\alpha$ particles.

When a strong beam of $\alpha$ rays passes through oxygen or carbon dioxide only a few $H$ atoms are observed, and these appear to come from the radioactive source. When, however, the rays pass through dry nitrogen a much greater number of penetrating particles is observed. Rutherford has shown by the action of a magnetic field that these particles are not atoms of nitrogen but probably charged atoms of hydrogen. Rutherford and Chadwick have tested a number of elements in this way and have found that, in addition to nitrogen, boron, fluorine, sodium and phosphorus show a similar property. As far as observation has gone it seems probable that these expelled particles are $H$ atoms which are released by the disintegration of the nucleus. The velocity of expulsion of such $H$ atoms is greater than that of an $H$ atom in a direct collision with an $\alpha$ particle. For example, using $\alpha$ particles of range 7·0 cm. in air, ordinary $H$ atoms travel 29 cm. in air while the atoms from nitrogen go 40 cm., and those from aluminium not less than 80 cm. It thus seems clear that the effects observed in nitrogen and aluminium cannot be ascribed to ordinary hydrogen as an impurity. It is of interest to note that if the particle from aluminium is an $H$ atom it is released with more energy than that of the incident $\alpha$ particle. Elements like carbon, oxygen, and sulphur, whose atomic mass is given by $4n$ where $n$ is a whole number, do not give rise to $H$ atoms, but only those elements whose mass is given by $4n+2$ or $4n+3$. It thus seems clear that a disintegration of certain atoms can be produced by the intense collisions with the $\alpha$ particle in which an $H$ atom is released with great velocity. General evidence indicates that not only $H$ atoms but possibly also atoms of mass 3 or 4 may be liberated in a similar way, but the experimental evidence was in 1921 too indefinite for any certain conclusion.

It should be borne in mind that the disintegration observed in this way is on an exceedingly small scale. Not more than one particle in a million gets sufficiently close to a nucleus to release an $H$ atom. It seems clear, however, that while the ordinary atom is undoubtedly very stable, its disintegration can be brought about by the aid of sufficiently powerful agencies which are able to penetrate its structure. As already pointed out, there are strong reasons for believing that the helium nucleus is a very stable structure which cannot be broken up even by the swiftest $\alpha$ particle at our disposal.

While it is reasonable to suppose that all the elements have been built up by combinations of protons and electrons, there was in 1921 no experimental evidence to throw light on the conditions necessary to lead to the formation of complex nuclei. No doubt, however, this process of aggregation has gone on in the past, and may still be in progress under favourable conditions, if not on this earth at any rate on some of the stars. (E. Ru.)

**MAUBEUGE, SIEGE OF (1914).**—The fortress of Maubeuge, which in oldtime wars played an important rôle as commanding the routes leading from the Spanish or Austrian Netherlands to the Oise valley, was reconstructed as a ring fortress of the modern type between 1878 and 1896, under the defence scheme of Gen. Séré de Rivières. Its function, like that of Besançon on the other flank of the French eastern front, was in substance to absorb the forces of a German army which should seek to turn the flank of the Lorraine-Meuse defence. The great development of communications of all sorts in north-eastern France

and Belgium had robbed the place of its former significance as a road centre and river crossing, but on the other hand it was the junction of several lines of railway, and the control of these by fortifications was justified, if not absolutely essential. By 1914 however, conditions had altered considerably. Progress in siege artillery equipment had made Séré de Rivières' designs obsolete, and French mobilization plans had been so far perfected that it was thought possible to initiate operations by an offensive from the eastern front towards the Saar. In these circumstances the French General Staff was confronted with the choice between spending large sums of money on modernizing Maubeuge, or else treating it as a place of subordinate importance; and thus the door was opened for differences of opinion which resulted in the place being neither modernized nor demilitarized. The question of reconstruction was put aside as of "no immediate interest until work on the eastern fortresses has been completed." In 1910, the governor was officially informed that he was not expected to hold out more than a few days if attacked, and that "the hypothesis of an isolated defence against regular siege need not be considered." On the verge of hostilities Joffre told General Fournier, the recently appointed governor, that he would probably employ him and his 30,000 war garrison to besiege Metz.

The ring of forts and internal works had an average diameter of about 4 miles. In the main, the fortifications were high-command works of earth and masonry, but some of the newer works had concrete shelters, two of the eastern forts (Cerfontaine and Boussois) possessed each an old type cupola, and Forts Hautmont and Le Bourvian on the slope south of the town and Fort des Sarts north of it were modernized about 1910. In the first days of mobilization the intervals were converted as usual with artillery positions into infantry redoubts, trenches and wire in front of them, and in some cases the forts themselves were treated as the nuclei of groups of field works.

But already in the mobilization period local difficulties, uncertainties as to the real rôle of the place, lastly, reports of the Germans passing to the left of the Meuse at Huy, had brought about a crisis. The Minister of War, M. Messimy, alarmed by the governor's reports, published a decree dismissing him from his post and, moreover (according to General Pau's evidence before the subsequent court-martial), sent Pau to Maubeuge with instructions to have him shot. Pau, however, was satisfied with what he saw and the decree was cancelled. Thus the defence was morally disorganized from the start, and the collapse of Liége and Namur, both fortresses of concrete and armour, before the 42-cm. and 30·5-cm. howitzers of the enemy, made it evident that resistance could not be maintained for long even before a German patrol had appeared. Finally, the retreat of the French V. Army on the right of the place and of the British forces on the left of it, left Maubeuge exposed to the

very form of attack which, officially, it was not expected to meet —investment and regular siege. Owing to its control of rail communications, however, it was important to hold Maubeuge for as long as possible, and the Government gave no instructions relieving the fortress commander of his legal liabilities.

On their side, the Germans, as they pressed on in pursuit of the French and British field forces, at first gave little attention to Maubeuge. A slender cordon of investment was put round it by the first troops which came up, but responsibility for this investment was passed from hand to hand for several days till finally Gen. von Zwehl, with half his VII. Res. Corps (14th Res. Div.) and a brigade of the VII. Active Corps, was left in charge of the operation. It was estimated that the French garrison numbered 7,000; in reality its strength was 40,000 to 45,000. For their part the French seemed to have been equally ignorant of the strength of the investing force, which at first was not more than 10,000.

The plan of attack, proposed by the artillery general who had reduced Liége and Namur, and adopted by von Zwehl, was a main attack on the north-east point (Salemagne Work–Fort Boussois) and a succeeding attack south of the Sambre on Rocq Work and Fort Cerfontaine. The method was that of pure bombardment accompanied by a careful advance of the infantry as close to the objective as possible and followed by assault after the ruin of the defences. But its application was in this instance limited by two factors, the numerical weakness of the besiegers and the shortage of ammunition for the siege artillery, and during the progress of the siege there were several differences of opinion as to procedure between the commander, the artillery general and the engineer general concerned. Thus the record of this siege, as compared with those of Liége and Namur where ammunition could be poured out, is one of slow, careful and somewhat hesitating advance, and it was this principally which enabled the place, in spite of its technical weaknesses, to hold out longer than either of the Belgian fortresses.

The loose investment which had begun on Aug. 25 was first regularized, but the forces available only allowed of the west front being watched by a few squadrons of cavalry in the Autnois region, and the line of defence in front of the siege artillery emplacements scarcely extended far enough north to give adequate protection to the most important of the batteries, viz. the 42-cm., placed near Givry. But, as it turned out, no *coup* was attempted by the garrison, and the siege artillery was gradually put in position east of the fortress during Aug. 28–31, batteries opening fire successively. It formed two main groups north of the Sambre and a scattered group south of it. The 42-cm. battery and two German 30·5-cm. batteries and one battery of medium guns were S.E. of Givry; two Austrian 30·5-cm. batteries, one (afterwards two) of 21-cm. howitzers, and three of medium guns and howitzers, between Erquelinnes, Peissant, Merbes-en-Chateau; and two 21-cm. batteries (afterwards one) and one of medium guns in the wooded valleys south of the Sambre.

Owing to shortage of ammunition, these siege batteries fired only slowly during Aug. 30, while the French from other forts and interval-batteries fired now heavily, now not at all, with the purpose of confusing the ideas of the attack and perhaps enticing the Germans into a premature assault; in this object they very nearly succeeded on Aug. 31 when the German artillery general urged von Zwehl to storm at once. In the end however, von Zwehl declined the proposal. The second division of his VII. Res. Corps (the 13th Res.), hitherto detained at Liége against the contingency of insurrections, only began to arrive piecemeal on Aug. 31 and it had to be used chiefly to complete the investment on the west side. Moreover, he was continually being pressed to give up the brigade borrowed from the II. Army, notably at the time of the battle of Guise when that army was in difficulties. Including this brigade, and all forces of the 13th Res. Div. which had arrived before the end of the siege, the final infantry strength of the siege force was no more than 27 battalions, which were distributed (unequally, of course) over a perimeter of some 60 kilometres.

The bold policy of Namur was obviously impossible here, and the guns were allowed to continue their slow bombardment till the works should be reported as beyond question "storm-ripe." Till the arrival of two aeroplanes on Sept. 2, no definite idea was obtained either of the damage caused by the bombardment or of the internal dispositions of the enemy whose sorties, on Sept. 1, though repulsed, were an additional incentive to caution in the attack procedure. Even on Sept. 3, when it had become known from air observation that Fort Boussois and Salemagne Work were badly damaged, no drastic action was taken.

On Sept. 4, however, the siege entered on a new phase. Calls from the II. Army on the Marne for the return of the borrowed brigade and, even more, reports of the landing of a great army of Russians at Ostend—the latter so convincing that at one time it was under consideration to give up the siege altogether—showed von Zwehl that he must force the issue. Accordingly, on Sept. 5 the German infantry was launched to the assault of Bersillies and Salemagne works, which were carried, and pushed close up to Fort Boussois, in front of which heavy trench mortars were emplaced during the night of Sept. 5–6. A secondary attack on Rocq Work, south of the Sambre, was repulsed. Next day, Sept. 6, Fort Boussois and Rocq Work were stormed, and a general advance was begun from the front Bersillies–Rocq toward Maubeuge while the siege artillery changed positions forward. The resistance of the retiring French infantry however was stubborn, and von Zwehl suspended further penetration till the forts on either side of the breach should have been reduced, viz. Les Sarts, Héronfontaine and Leveau on the N. and N.E. fronts and Cerfontaine on the south-west. Thanks to the arrival of a second battery of 42-cm. guns (on railway mountings) from Mons, and to the expenditure of almost the last rounds of the 42-cm. and 30·5-cm. at Givry (the 21-cm. ammunition was already exhausted), all these works were in the hands of the Germans in the early afternoon of Sept. 7. Thereupon Fournier, the *moral* of whose troops had been completely broken down by a week's bombardment, surrendered with some 40,000 men, plus 377 guns, just as von Zwehl received a peremptory order from von Bülow to send the 29th Infantry Brigade south at once.

The resistance of Maubeuge had lasted for 9 days (counting from the opening of the bombardment), longer than that of Liége or Namur and nearly as long as that of Antwerp, and had kept five brigades of active and reserve infantry occupied during the critical days of the battle of the Marne. If the duration of the defence was due largely to the weakness of the attack, and notably to the shortage of siege ammunition, it must not be forgotten on the other hand that the majority of the forts were completely antiquated, and that the troops of the mobile defence consisted in the main of men of the older and oldest classes, unsuited to field service. General Fournier, after being subjected to bitter persecution, was brought to trial by a court-martial early in 1920 and completely exonerated.

After the surrender, the Germans decided not to retain Maubeuge as a *point d'appui*, and blew up all the works.

(C. F. A.)

**MAUDE, CYRIL** (1862– ), English actor (*see* 17.904*), produced *Rip Van Winkle* at the Playhouse, London, in 1911, and *The Headmaster* in 1913. Between 1911 and 1919 he acted, largely in America, where he played in *Rip Van Winkle*, *Grumpy*, *The Headmaster*, *Lord Richard in the Pantry* and other modern comedies. He returned to London in 1919 and established himself at the Criterion theatre.

**MAUDE, SIR (FREDERICK) STANLEY** (1864–1917), British general, son of Gen. Sir Frederick Maude, V.C., was born at Gibraltar June 24 1864. Educated at Eton, he entered the Coldstream Guards in 1884, and early in the following year proceeded with his battalion to Suakin and took part in the operations undertaken in connexion with the contemplated Suakin-Berber railway. He was battalion adjutant from 1888 to 1892, married Cecil, daughter of The Rt. Hon. Col. T. E. Taylor, in 1893, and joined the Staff College in 1895. On completion of the course he became brigade-major in the Home District, which post he held till the end of 1899, when he was sent out to South

** These figures indicate the volume and page number of the previous article.*

Africa. As brigade-major of the Guards Brigade there he took part in Lord Roberts' advance from Cape Colony to Bloemfontein, in the advance to Pretoria, and in the subsequent advance by Belfast to Komati Poort. The brigade moved to the Orange river in the latter part of 1900, and Maude was for some time on the staff in that region before proceeding, early in 1901, to Canada as military secretary to the governor-general. For his services in South Africa he was given the D.S.O. He remained in Canada till 1895, receiving the C.M.G., and then returned to regimental and staff service at home. He took an active part as a lieutenant-colonel on the staff, in the development of the organization and training of the new Territorial Force. He was appointed to the War Office in 1909 as a full colonel, and was transferred to the staff of the 3rd Division at the Curragh in 1912, but was recalled to the War Office early in 1914 and, on mobilization in Aug., was posted to the staff of the III. Army Corps. He served with his corps on the Aisne and during its transfer north to Flanders, and then commanded the 14th Brigade with signal success until June 1915, having been wounded and given the C.B. in April. Promoted major-general for distinguished service, he was hurried out to the Dardanelles in Aug. to take up command of the 13th Division. There he played a conspicuous part in the successful evacuations of Suvla and of Helles, and on its being decided early in 1916 to dispatch a British division from Egypt to Mesopotamia to aid in the relief of Kut, his was chosen. They arrived in time to bear a share in the final desperate endeavours to save the doomed stronghold but the effort came to naught and after the surrender of Kut, Maude and his division remained facing the Turks on the Tigris. He had shown himself to be a skilful and resolute leader of men and was in July appointed commander of the army corps constituting the forces at the front, to be advanced in Sept. to the position of army-commander in Mesopotamia.

Realizing that victory in this theatre of war must hinge on effective organization and adequate preparation, Maude, who had been given the K.C.B., spent three months at Basrah, ensuring that when the time came his field army should be capable of acting with vigour and decision. Then, when all was ready early in Dec., he suddenly pushed forward and within a few weeks had driven the Turks in confusion out of their entrenched camp around Kut. Moving relentlessly on and making great captures he occupied Bagdad March 11. This memorable achievement he followed up by trenchant operations, which rapidly secured him a considerable area around the city and inflicted a succession of damaging strokes against the enemy, so that by May his forces could settle down in security for the hot weather. He was rewarded by promotion to lieutenant-general.

His genius for administration and grasp of military requirements were constantly in evidence during the ensuing summer. While interesting himself closely in the welfare of his troops and assuring his communications with the Persian Gulf, he was framing plans for a fresh offensive as soon as the season should become suitable. This had, however, only just made a promising commencement when, to the consternation of his army, over which he had gained a remarkable personal ascendancy, he was struck down by cholera and died at Bagdad Nov. 18 1917. His record since 1914 had been that of a great soldier. As a brigadier and divisional commander he had won to an unusual extent the confidence of superiors and subordinates. As an army commander, operating in a region that offered extraordinary difficulties to the conduct of warfare on a great scale, he had made strategy and administration move hand in hand, and had framed and carried into execution plans of campaign at once comprehensive, judicious and bold. His conquest of Mesopotamia and his transformation of a depressing situation into one of signal triumph ranks as one of the finest feats in modern military history.

See *Life* by Maj.-Gen. Sir C. E. Callwell (1920).

**MAUDSLEY, HENRY** (1835–1918), English physiologist, was born at Thorne, near Settle, Yorks., Feb. 5 1835. He was educated at Giggleswick and at University College hospital, London, taking his M.D. degree in 1857. From 1862 to 1878 he edited the *Journal of Mental Science*, and from 1869 to 1879 he was professor of medical jurisprudence in University College, London. Amongst his published works were *Responsibility in Mental Disease* (1874); *Physiology of Mind* (1876); *Pathology of Mind* (1879); *Body and Will* (1883); *Life in Mind and Conduct* (1902); *Organic to Human* (1916). The views expressed in all his writings were those of medical materialism. In 1908 he gave a sum of £30,000 to the London County Council Asylums Committee to be devoted to the study of mental science. He died at Bushey Heath, Herts., Jan. 23 1918.

**MAUNOURY, MICHEL JOSEPH** (1847– ), French general, was born at Maintenon (Eure-et-Loir) Dec. 11 1847. His family, long established on the soil, is said to have given devoted assistance to Pasteur in his researches on animal chemistry. Entering the École Polytechnique in 1867, and commissioned to the artillery in 1869, he took part in the war of 1870, and at the battle of Champigny he won the Legion of Honour. In 1874 he became captain, in 1881 he entered the staff college, and in 1883 was appointed to the staff of St. Cyr. In 1897 he became colonel, in 1901 general of brigade and in 1906 general of division. His career had been unusually varied; in addition to regimental service in all ranks of the artillery, both field and fortress, he had served on the technical artillery committee, the powders committee, and the military education commission, and had been deputy chief of the general staff at the War Office and director of the École de Guerre. Lastly, as a corps commander he had been placed at the head of the famous frontier corps, the XX., stationed at Nancy. He retired in 1912 on reaching the age limit, his last appointment being as military governor of Paris and a member of the Conseil Supérieur de la Guerre, formed of generals designated for army commands in war.

Shortly after mobilization in Aug. 1914 he was recalled to the active list, and appointed, practically on the field of battle, to command the improvised "Army of Lorraine," with which he won the battle of Aug. 25 on the Othain line—a remarkable success in the midst of disaster. But his pursuit of the Germans was stopped by the break-up of his army on the evening of victory. Maunoury himself and certain of his units, reinforced by others, were dispatched to the region of Montdidier–Amiens, and became the VI. Army, which, remaining outside the sweep of the German advance, found itself on Sept. 4 in the positions N.E. of Paris from which it was launched against the flank of von Kluck's I. Army. In the battle of the Marne the duel of Maunoury and von Kluck was the turning-point. Maunoury continued to command the army during the development of the Aisne line of battle towards the sea, and in the first phases of trench warfare. But on March 15 1915 he was severely wounded, and subsequently had no active command. From Nov. 1915 to March 1916 he was governor of Paris.

**MAURITIUS** (*see* 17.912).—At the 1911 census the pop. (exclusive of the dependencies of the colony) was 370,393, of whom 222,361 were Indo-Mauritians, that is descendants of Indian immigrants. There were 35,526 other Indians and 3,662 Chinese. The "general population," *i.e.* persons of European, African or mixed descent, numbered 108,844. There was a decrease of 2,232 inhabitants compared with the 1901 census, the first decrease recorded since the 1841 census. In Jan. 1920 the estimated pop. was 364,493. This was a decrease of 12,320 compared with the previous year, a result largely attributed to an epidemic of influenza in May–July 1919, which caused the death of over 11,000 persons. Port Louis, the capital, had 50,060 inhabitants in 1911.

The period 1910–20 was one of marked prosperity in Mauritius, and also of continued dependence on one crop—sugar. The official report for 1911 recorded that the sugar crop of 1909–10 was the largest and most valuable, and the revenue higher than in any previous year; the official report for 1919 again recorded an increase in the volume of trade unprecedented in the history of the colony and a revenue also in excess of that received in any previous year.

The following figures give particulars of trade, revenue and shipping for 1910, 1915 and 1919. The currency is in rupees.

Value of external trade: 1910, exports 37,109,000 Rs., imports 37,545,000 Rs.; 1915, exports 56,220,000 Rs., imports 48,063,000 Rs.; 1919, exports 127,806,000 Rs., imports 47,037,000 Rs.

Revenue and expenditure (the financial year ends June 30): 1910, revenue 10,799,000 Rs., expenditure 9,449,000 Rs.; 1915, revenue 12,113,000 Rs., expenditure 12,136,000 Rs.; 1919, revenue 13,813,000 Rs., expenditure 14,711,000 Rs.

Shipping: Tonnage entered and cleared 1910, British 763,000, total 986,000; 1915, British 564,000, total 763,000; 1919, British 509,000, total 648,000.

In normal years before the World War the bulk of the sugar crop went to Indian markets, though when there was a failure of the beet-sugar crop large quantities of Mauritius sugar were diverted to Europe. Thus in 1910 France took 51 tons of sugar from the island, but in 1911 the quantity rose to 19,500 tons. Exports to Australia, formerly about a third of the total crop, had fallen in 1911 to 1,500 tons owing to Queensland becoming a sugar-producing country. The development of the Natal sugar estates had also, by 1914, deprived Mauritius of the South African market. On the outbreak of the World War the British Government purchased the bulk of the island's sugar, and this purchase was repeated in the four succeeding years. The high state of efficiency of the industry, largely the result of the exertions for many years of Mr. P. Bouâme, director of the agricultural station at Le Reduit, enabled the British Government to obtain the supplies required, both in quality and quantity. As to quantity, the sugar crop in 1910–1 had been 214,000 metric tons, in 1918–9 it was 252,000 tons. In 1919 the high-water mark of production was recorded to have been reached. Practically the whole area, some 180,000 ac., suitable for cane-growing was under cultivation. Over a third of the sugar estates are held by small planters, of whom the great majority are of Indian origin.

The British Government purchased the sugar at the world's ruling prices and during the war the planters grew very rich. The value of the crops in the period 1915–9 was nearly double its pre-war price. Many planters invested their profits in the development of new plantations in Natal, Réunion and Madagascar. A coöperative scheme was also launched with the object of enabling planters to sell their produce in the best market instead of having, as before the war, to depend mainly on the Indian markets. The Government for its part devoted 20,000,000 Rs. to improvements of the harbour of Port Louis and in irrigation and sanitation works. Mauritius suffered but slightly from the general economic depression of 1920–1. Socially there was progress in well-being; labour troubles were unknown, and education increased. Many of the European planters sent their sons to England to be educated. Some progress too was made in developing subsidiary industries, though nothing great had been achieved by 1921, and Mauritius remained almost entirely dependent on imports for food. The imports came mainly from India (rice, flour, etc.), the United Kingdom (textiles and machinery), and from South Africa (coal, wine, maize). The share of foreign countries in the external trade was about 25 per cent.

Politically the period 1910–21 was marked by cordial coöperation between the people and the administration. Sir Cavendish Boyle was succeeded as governor in Nov. 1911 by Major (afterwards Sir) John R. Chancellor (b. 1870), who had served with distinction in the Tirah expedition (1897–8), and in other campaigns and had been secretary to the Imperial Defence Committee. Sir John Chancellor paid particular attention to local feeling, as did his successor, Sir Hesketh Bell, who became governor in May 1916 on Sir John Chancellor's transference to Trinidad. The influence of leading Mauritians such as Dr. Eugène Laurent (11 years in succession mayor of Port Louis), Sir Henry Leclézio and Sir Célicourt Antelme, as well as that of the leaders of the Indians, was successfully directed to the improvement of social and economic conditions. The island helped liberally both in men and money in the World War and as late as 1921 a Mauritian Volunteer Battalion was on active service in Mesopotamia.

During the Peace Conference in Paris (1919) a small section of the Creole population (that is, the Europeans of French descent) started an agitation for the retrocession of the island to France. They had not the sympathy of the majority of the French-speaking inhabitants and opposition to the movement was organized under the leadership of Dr. Laurent and Mr. A. Duclos. At the elections to the Legislative Council held in Feb. 1921 all the candidates who advocated the retention of the British connexion were returned by large majorities.

See the annual reports issued by the Colonial Office, London; the *Mauritius Almanac*; A. Macmillan, *Mauritius Illustrated* (1914); D. E. Anderson, *The Epidemics of Mauritius, with a descriptive and historical account of the Island* (1918); P. Carie, "L'île Maurice" *La Geog.* vol. lii., (1919); R. E. Hart, *Les Volontaires Mauriciens aux armées* (1919), and the report of the Mauritius Royal Commission (Cd. 5186) issued in 1910, a valuable guide to the economic condition of the island. (F. R. C.)

**MAX (OF BADEN),** PRINCE (1867– ), was born on June 10 1867 at Baden-Baden, the son of Prince William of Baden. As the nearest agnate to the reigning Grand Duke, of whom he was a cousin twice removed, he was heir presumptive to the grand-ducal throne. He studied law and then entered the army, in which he attained the rank of lieutenant-general on quitting the service in 1911. On the outbreak of the World War he was promoted to the honorary rank of general of the cavalry. From 1907 to 1918 he was president of the First Chamber of the Baden Diet. His family had always had English friends, and during the war Prince Max played a useful part behind the scenes in helping to improve conditions for English prisoners in Germany. He played a similar part on behalf of German prisoners, especially in Russia, where he was able to obtain some amelioration of their treatment. On Oct. 3 1918, when the old régime was already tottering to its fall and the German armies in France were being driven back towards the frontier, he was appointed Imperial Chancellor, partly no doubt because of the moderating rôle he had adopted earlier in the war when the probability of peace was being discussed. It fell to his lot to initiate the negotiations for the Armistice, and also to carry through in hot haste those alterations in the old constitution which had long been demanded by the Liberals and the Socialists, but which now came too late to avert the fate of the empire and the Prussian Monarchy. It also became his duty to put pressure upon the Emperor in order to induce him to abdicate. As the Imperial decision was delayed from day to day and the revolution became imminent, he had to take it upon himself to declare, on Nov. 9 1918, the abdication of William II. as German Emperor and as King of Prussia. For a moment it seemed as if he were about to assume the regency, perhaps on behalf of the Crown Prince's eldest son, a young boy, but the hopelessness of such an expedient having become apparent he handed over the control of the Government (Nov. 10) to the majority Socialist leader Ebert, who became the president of the German Reich. The sincerity of Prince Max's liberalism came into question after a private letter full of anti-democratic sentiments, which during the war he had addressed to his cousin Prince Alexander Hohenlohe, had been published by the latter in the Swiss press. He continued after the revolution to publish occasional articles dealing with the situation in Germany before the revolution, and in particular with Ludendorff's action in urging the Government on Oct. 1 1918 to ask for an immediate armistice, and then eight days later, after they had acted in that sense, endeavouring to persuade them that the matter was no longer urgent. He continued, after the abdication of the Grand Duke, to reside at Karlsruhe.

**MAX, ADOLPHE** (1869– ), burgomaster of Brussels at the outbreak of the World War, was born at Brussels Dec. 31 1869, and was educated at the university of his native city. He entered the legal profession, also doing journalistic work, and at the age of 25 was appointed provincial counsel for Brabant, becoming communal counsel in 1903. After serving as magistrate, he was elected burgomaster of Brussels Dec. 6 1909, and distinguished himself by his administrative qualities. In Aug. 1914 M. Max showed the greatest coolness and did his best to calm the populace. On Aug. 20 he met the German army as it approached Brussels, and protested against the conditions imposed by the conquerors on the city. He succeeded in inducing the Germans to abandon that clause of the terms by which the burgomaster, the communal counsel and one hundred citizens were required to surrender themselves as hostages. He refused to sign a convention requiring that he should perform his duties only under the authority of the military governor of Brussels, and reserved to himself the rights of a free agent. The same day he charged his fellow-citizens to keep the national flag flying on their houses. Some of his public announcements became famous, notably that of Aug. 30, in which he gave a formal denial to a false statement of the German governor of Liége, and that of Sept. 16, in which he attempted to calm those of the inhabitants who had been ordered

to remove the national flag from their houses. The latter ended with the words "Attendons patiemment l'heure de la réparation." The same evening he was arrested, and though soon released, was again arrested on Sept. 26 owing to a difference with the German authorities as to the amount of the war levy to be paid by the city of Brussels. He was sent to Namur, thence to Cologne and various other towns, being finally sent to Berlin (Oct. 1916), where he was closely confined. On Oct. 30 1918 he was interned at Goslar, whence he escaped on Nov. 13. He was received at Brussels with extraordinary enthusiasm; he was appointed a minister of state, named in a national order of the day, and was elected a member of the Académie Royale de Belgique and vice-president of the Conseil Supérieur du Congo. In 1919 he was elected to the Chamber of Representatives.

**MAXIM, SIR HIRAM STEVENS** (1841–1916), Anglo-American engineer and inventor (*see* 17.918), died in London Nov. 24 1916.

His younger brother, HUDSON MAXIM (1853– ), was born Feb. 3 1853 and educated at the Maine Wesleyan Seminary at Kent's Hill, Me. He began life in a printing and publishing business, but in 1888 took up the ordnance and explosives work in which his brother was interested, and invented a smokeless powder called "maximite," the formula of which he sold to the U.S. Government in 1901. He afterwards produced "stabillite," another smokeless powder, as well as "motorite," a self-combustive material for driving automobile torpedoes, and a special form of torpedo-ram. In Sept. 1915 he was made a member of the Naval Consulting Board. He published *The Science of Poetry and the Philosophy of Language* (1910); *Defenseless America* (1915) and *Dynamite Stories* (1916).

**MAXWELL, SIR JOHN GRENFELL** (1859– ), British general, was born July 11 1859. He joined the army in 1879. He served in Egypt in 1882 and in the Nile expedition of 1884–5 and was then seconded to serve with the Egyptian army, with which he spent many years, taking part in all its successive campaigns against the forces of the Mahdi, and finally commanding a brigade during the advances up the Nile (1896–8) which closed with the reoccupation of Khartum; this gave him the rank of full colonel in the British army. He served on the staff during the S. African War and was given the K.C.B. and C.M.G. for his services. He subsequently filled important staff appointments, was promoted major-general in 1906, and was in command of the British troops in Egypt from 1908 to 1912.

A lieutenant-general on the outbreak of the World War, he acted for a few weeks as liaison officer with the French headquarters and was then sent out to take charge of the forces which were arriving in Egypt from the United Kingdom, India and Australasia. Egypt during the months following represented at once a vast depot and training centre, a base for the army in the Gallipoli Peninsula, and a theatre of war in itself, seeing that the Turks threatened the country from the east and the Senussi from the west. His responsibilities were wide and varied, and, in so far as the security of the Nile Delta was concerned, his defensive measures were most successful, as the one serious advance which the Turks attempted was beaten off decisively. He was given the K.C.M.G. for his services and returned to England in March 1916. The Irish rebellion broke out a few weeks later, and Maxwell was thereupon entrusted with the command of the troops in Ireland. He remained there until the autumn, and then was given command of the Northern District in England, which he held for two years. He was promoted full general in 1919.

**MAYBRICK, MICHAEL** (1841–1913), English singer and composer, was born at Liverpool Jan. 31 1841. He was educated at Liverpool, and studied singing in Italy and Germany, subsequently appearing with great success as a baritone singer in England. It was as a composer of popular songs, however, under the *nom-de-plume* of "Stephen Adams," that he became best known, his most popular works being *Nancy Lee*, *The Star of Bethlehem*, *The Holy City*, *A Warrior Bold*, *Long Live the King*, etc. He died at Buxton Aug. 26 1913.

**MAYO, HENRY THOMAS** (1856– ), American naval officer, was born at Burlington, Vt., Dec. 8 1856. He graduated from the U.S. Naval Academy in 1876 and after passing through the usual stages of promotion became captain in 1908. From 1911 to 1913 he was commandant of the Mare Island navy yard and in the latter year was promoted to rear-admiral. In 1915 he was given the rank of vice-admiral and was in command of the squadrons of the Atlantic Fleet. The following year he was promoted to admiral and made commander-in-chief of the Atlantic Fleet, which position he held during America's participation in the World War. In 1918 he visited England, France and Italy on a tour of inspection. In 1919 his rank reverted to that of rear-admiral.

**MAYO, WILLIAM JAMES** (1861– ), American surgeon, was born at Le Sueur, Minn., June 29 1861. His father, William Worrall Mayo, migrated when a boy from England to America, studied medicine, and served as surgeon at several army posts before settling at Rochester, Minnesota. Here the son, after graduating in medicine from the university of Michigan in 1883, began the practice of surgery. A small hospital was organized under the local branch of the Sisters of St. Francis, the outgrowth of which was St. Mary's hospital. Here he and his younger brother, Charles Horace, developed the Mayo Clinic (organized 1889), which became famous throughout the world for the number and success of operations performed. The elder brother was elected president of the Minnesota State Medical Society in 1895, and in 1907 was appointed a regent of the university of Minnesota. He was elected president of the Society for Clinical Surgery in 1911 and the following year president of the American Surgical Association. On America's entrance into the World War he was appointed colonel in the Medical Corps, U.S. army, and chief consultant for surgical service. In 1919 he was awarded the D.S.M.

CHARLES HORACE MAYO (1865– ), American surgeon, was born at Rochester, Minn., July 19 1865. After studying at Northwestern University and the Chicago Medical College (M.D. 1888), he began the practice of surgery at Rochester, Minn., and with his brother became surgeon at the Mayo Clinic. He was elected president of the Minnesota State Medical Society in 1905, president of the surgical section of the International Tuberculosis Congress in 1908, and president of the American Medical Association in 1916. He was appointed Mayo Foundation professor of surgery in 1915. During 1917–8 he was president of the examining board of applicants for commissions in the Medical Corps, having supervision over several states, including Minnesota. In 1918 he was appointed colonel in the Medical Corps and for a year was associate chief consultant for surgical service. Beginning with 1912, graduate courses in medicine were offered at the Mayo Clinic in Rochester. Early in 1915 the Mayo Foundation for Medical Education and Research was incorporated, and to it the brothers gave $1,500,000. In June of the same year, by mutual agreement, the funds and resources of the Foundation were placed under the direction of the regents of the university of Minnesota for promoting "graduate work in medicine and research in this field." On Sept. 13 1917 the Foundation, with its fully-equipped staff, laboratories and clinics in Rochester, became a department of the university.

**MAYOR, JOHN EYTON BICKERSTETH** (1825–1910), English classical scholar (*see* 17.937), died at Cambridge Dec. 1 1910.

His brother, JOSEPH BICKERSTETH MAYOR (1828–1916), died at Kingston Hill, Surrey, Nov. 29 1916.

**MEATH, REGINALD BRABAZON, 12TH EARL OF** (1841– ), British philanthropist, was born July 31 1841 in London. He was educated at Eton and in Germany, and in 1863 became a clerk in the Foreign Office. In 1868 he entered the diplomatic service and was sent to Berlin, leaving Germany for The Hague in 1870. From 1871 to 1873 he was in Paris after the conclusion of the Franco-Prussian War. Subsequently he devoted himself to various philanthropic and municipal undertakings in Ireland and London. In 1879 he became the first chairman of the Young Men's Friendly Society; he also became chairman of the Metropolitan Public Gardens Assn., and was founder of the Empire Day movement. His publications include *Social Arrows* (1886); *Social Aims* (1893); *Great Britain in Europe* (1901); *Great Britain in Asia* (1905); *Imperial and Social Subjects* (1906).

**MECCA** (*see* 17.950), the great Holy City of Islam and capital of the Hejaz, had a resident pop. in 1916 estimated at about 70,000, including some 12,000 Indians. The annual pilgrimage brings normally at least 200,000 visitors to the city, of whom pilgrims from British India and the Malay States number as many as 25,000. Pilgrims from Egypt, by way of the quarantine station of Tor, numbered 14,500 in 1913, decreasing to 84 in 1914. During the early stages of the Arab revolt in 1916 the pilgrimages practically ceased from all parts; on their partial resumption in 1916–7 about 58,000 pilgrims arrived, mostly by way of Jidda, the Hejaz railway at that time being held by the Turks and the caravan roads across the peninsula by way of Jebel Shammar being unsafe. Communication between Mecca and Medina was interrupted from June 1916 until Jan. 1919 (when the Turks surrendered Medina), so that the visit to the Haram of the latter city—not strictly forming part of the pilgrimage—could not be performed during that period. On the capture of Mecca at the outbreak of the Arab revolt in 1916, the Turks opened fire with their artillery on the Great Mosque, and Sherif Huscin indicted them, in his proclamation dated 25 Sha'ban 1334 A.H., with having done material damage to the *kiswa* and Ka'ba.

The geographical position of Mecca was observed during war operations but was not fixed precisely, some further adjustments being necessary. The general aspect of the city had changed but little, though some modern buildings had sprung up; there were a number of stately residences, including the new king's palace of six storeys, and there is a considerable display of wealth. The sanitation of the city had made progress under the insistence of the King, and the water-supply, previously in a deplorable condition, had been improved. Much more strict hygienic precautions were reported to have been taken during pilgrimages. Some improvement had been effected in the Meccan postal and telegraphic arrangements, the Hejaz having become a member of the International Postal Union with its own issue of stamps, printed (1920) in Cairo. There was telegraphic communication between Mecca and Jidda, and between Mecca and Taif, the summer residence of the King 75 m. S.E. Before the war a weekly paper, *El Hejaz*, was published in Turkish and Arabic; a new weekly, *El Kibla*, was founded as the organ of the Government after the declaration of independence (1916), and a Hejaz agency was established at Cairo.

**MECHNIKOV, ILYA [ELIAS]** (1845–1916), Russian biologist, was born in the province of Kharkov May 15 1845. His father was an officer of the Imperial Guard and his mother was a Jewess. At the age of 17 he entered the Kharkov University and two years later went to Germany for further biological training. In 1867 he returned to Russia and took his degree in zoölogy both at Odessa and Petrograd, becoming professor ordinarius of zoölogy and comparative anatomy at Odessa. In 1882 he went to Messina and there began his studies into the nature and habits of microbes. Henceforth he devoted himself to pathological study and in 1888 went to Pasteur in Paris, who encouraged him and gave him a laboratory in the École Normale. By 1892 his views on the essential importance of phagocytosis were firmly established. In that year he published *The Comparative Pathology of Inflammation*, followed in 1901 by his chief work, *Immunity in Infectious Diseases*, and a more popular treatise, *The Nature of Man* (1903). In later years he made a special study of the bacteria infesting the alimentary canal of man, and recommended a diet of sour milk. He was an hon. D.Sc. of Cambridge and Copley medallist of the Royal Society, a member of the Institute of France and of the Academy of Sciences of Petrograd, and in 1908 was awarded the Nobel prize for the benefits his researches had conferred upon humanity. He died in Paris July 16 1916.

See *Life* by his wife, Olga Mechnikov (1920), trans. by Mrs. R. L. Devonshire (1921).

**MEDALS AND DECORATIONS** (*see* 18.2; 15.860).—In the present article an account is given of British, American and other war medals and decorations created between 1910 and 1921, of new orders of knighthood considered as service decorations, and of changes in the insignia and the eligibility conditions of orders, decorations and medals existing in 1910.

### I.—British War Medals of the Period 1910–4

Before the war several new medals, as well as new issues of, and new clasps to, existing medals were authorized.

A new issue of the *African general service medal* was authorized in 1916 under Army Order 89 of 1916, bearing the effigy and titular legend of King George V. on the obverse. The conditions of award were similar to the old medal. Clasps: "East Africa 1913," "East Africa 1913–14," "East Africa 1914," "Shimber Berris 1914–15," "Nyasaland 1915," "Jubaland 1917–18," "East Africa 1918," "Somaliland 1920." Those already in possession of King Edward VII.'s medal received the bars only.

A new issue of the *India general service medal* of 1908 with the effigy of King George V. on the obverse, was made for later Indian frontier services. The clasp "Abor 1911–12" was authorized for the troops who took part in the Abor expedition of 1911–2 and the clasp "Afghanistan N.W. Frontier 1919" for service in the Afghan War of 1919.

The *Natal 1906 silver medal* was granted by the Natal Government in 1908 to all those who took part in suppressing the native revolt of 1906. Obverse: bust of King Edward VII. Reverse: an erect female figure representing Natal with the sword of justice in her right hand and a palm branch in the left, standing on a heap of native arms and supported by Britannia who holds the orb of empire in her left hand. In the background a group of natives with the sun bursting forth from behind the clouds. A clasp inscribed "1906" was issued with the medal. Ribbon: red with black edges.

The *Antarctic medal* was awarded to members of (1) Sir Ernest Shackleton's expedition of 1907 with clasp "Antarctic 1907–1909"; (2) Capt. R. F. Scott's expedition with clasp "Antarctic 1910–1913"; (3) the Mawson expedition 1912 with clasp "Antarctic 1912"; (4) Sir Ernest Shackleton's Imperial trans-Antarctic expedition of 1914–6 with clasp "Antarctic 1914–1916." The medal in bronze was granted to the crews of various relief ships at different dates, and is a separate decoration, which can be held in addition to the silver medal.

In 1915 a *naval general service medal* was awarded by King George V. for service in minor naval operations, whether in the nature of belligerency or police, of sufficient importance to justify the award of a medal where no other medal would be appropriate. Obverse: the head of King George V. in naval uniform. Reverse: a representation of Britannia and two sea-horses travelling through the sea. A clasp, "Persian Gulf 1909–1914," was authorized when this medal was established, for issue to officers and men of His Majesty's ships engaged in the suppression of arms traffic in the Persian Gulf. Ribbon: white with crimson borders and two crimson stripes.

A new *Khedive's Sudan medal*, having effect from 1910, was awarded by the Khedive in 1911. Obverse: the cypher of the Khedive and the date in Arabic. Reverse: a lion with forepaws resting upon a panel bearing the word "Sudan." Below, an oval native shield and spears. In the background the river Nile with palm trees and the rising sun. Clasps: "Atwot," "S. Kordofan 1910," "Sudan 1912," "Zeraf 1913–14," "Mongalla 1915–16," "Darfur 1916," "Fasher," "Lau-Nuer," "Atwot 1918." The medal without bar was given to troops engaged in operations in the Matong Mts., Mongalla, in 1916; and at various times the medal in bronze without the bar was awarded to certain classes of civilian followers.

### II.—British World War Medals

The issue of medals commemorating service in the World War is naturally the widest ever recorded. The long duration of the war, the fact that almost every part of the civilized world was involved in it, the great numbers of men and women taken into war service in different capacities, and to some extent popular feeling at different periods during and after the war, resulted in somewhat different principles from those of the past being observed in rewarding war service, all the more so as the conventional idea of "campaign" and "battle" ceased in a great measure to afford a guide in laying down regulations. Thus, in addition to the British general services war medal common to all who served in a theatre of war, the Allied and Associated Powers agreed upon a common medal to commemorate the united effort, and, within the British forces, the characteristic services of the original Expeditionary Force, of the men of the Territorial Force who had undertaken obligations and training in peace, of the war volunteers who formed the new armies of 1914–5 and of the mercantile marine were each recognized by the grant, under certain conditions, of a particular star or medal.

The stars and medals awarded and the general conditions qualifying for award are as follows:—

(1) *1914 Star.*—Awarded by King George V. under Army Order 350 of 1917. This decoration is a four-pointed star in bright bronze on which are superimposed two crossed swords and a laurel wreath. In the centre a scroll with the inscription "Aug. 1914 Nov." Ribbon: red, white and blue, shaded and watered. Granted to all officers, warrant officers, non-commissioned officers and men of the British and Indian forces, including civilian medical practitioners, nursing sisters, nurses and others employed with military hospitals,

who actually served in France or Belgium, on the establishment of a unit of the British Expeditionary Force, between Aug. 5 1914 and midnight of Nov. 22–23 1914.

The star was also granted to officers and men of the Royal Navy, Royal Marines, Royal Naval Air Service, Royal Naval Reserve and Royal Naval Volunteer Reserve who actually served in France or Belgium on the establishment of a unit landed for service on shore between the same dates. By Army Order 361 of 1919, a clasp to the star was authorized for issue to personnel of the naval and military forces who were actually present on duty within range of the enemy's mobile artillery and who were borne on the strength of certain specified units. The clasp is of bronze and bears the inscription "5th Aug.–22nd Nov. 1914." When only the ribbon of this star is worn in service or undress uniform, the possession of the bar is denoted by a small silver rose affixed to the centre of the ribbon.

(2) *1914–5 Star.*—Awarded by King George V. under Army Order 20 of 1919. This decoration is a bronze star, similar in shape and general design to the 1914 star, except that the inscription on the scroll is 1914–15, the words Aug. and Nov. being omitted. Ribbon: identical with that of the 1914 star. Granted to all personnel of the British, Dominion, Colonial and Indian forces, including civilian medical practitioners, nursing sisters, nurses and others employed with military hospitals who actually served on the establishment of a unit of the military forces in certain specified theatres of war between Aug. 5 1914 and Dec. 31 1915. These theatres of war comprised every locality in which troops of the British Empire were engaged against Germany and her allies during the period in question, with the exception that France and Belgium did not constitute a theatre of war for the award of this star till subsequent to midnight Nov. 22–23 1914. Individuals who earned the 1914 star are not eligible for the 1914–15 star.

The star was also granted to (*a*) all officers and men of the Royal Navy, Royal Marines, Royal Naval Air Service, Royal Naval Reserve, Royal Naval Volunteer Reserve, Royal Indian Marine and Dominion Naval Forces, who were mobilized and served at sea, or on shore within the specified theatres of military operations; (*b*) trained pilots and observers and men of the Royal Naval Air Service employed in flying from naval air-stations on overseas patrols; (*c*) mercantile marine officers and men serving under special naval engagements; (*d*) canteen staffs who served in a ship of war at sea.

(3) *British War Medal 1914–1918.*—Awarded by King George V. under Army Order 266 of 1919. Obverse: the effigy of the King. Reverse: a representation of St. George on horseback trampling underfoot the eagle shield of the Central Powers. A skull and crossbones in the foreground. Above, the rising sun of victory. The ribbon has an orange watered centre with stripes of white and black at each side and with borders of royal blue. Granted to record the bringing of the war to a successful conclusion and in recognition of the arduous services rendered by H.M. forces.

The medal in silver was awarded to the following classes who either entered a theatre of war on duty, or who left their places of residence and rendered approved service overseas, other than the waters dividing the different parts of the United Kingdom, between Aug. 5 1914 and Nov. 11 1918, both dates inclusive. (*a*) Officers, warrant officers, attested non-commissioned officers and men of the British, Dominion, Colonial and Indian military forces. (*b*) Members of women's formations, who were enrolled under a direct contract of service for service with H.M. Imperial Forces. (*c*) All who served on staffs of military hospitals and all members of recognized organizations who actually handled sick and wounded. (*d*) Members of duly recognized and authorized organizations. (*e*) Enrolled and attested followers on the establishment of units of the Indian army.

The medal in bronze was granted to all British subjects who were enrolled in native labour corps and who served in theatres of war. The medal was granted to the R.A.F. under similar conditions and also to personnel of the force who (i.) were actively engaged in the air against the enemy whilst borne on the strength of an operational unit in Great Britain; (ii.) were employed in flying new aircraft to France; (iii.) were on an aircraft-carrying ship.

The navy also participated in the grant of this medal, but the main condition of award differed in that it was given to all naval personnel who performed 28 days' mobilized service, or lost their lives in active operations before completing that period, between Aug. 5 1914 and Nov. 11 1918. The medal was also granted to personnel of the mercantile marine who served at sea for not less than six months between Aug. 4 1914 and Nov. 11 1918.

(4) *Victory Medal.*—This medal was the outcome of a meeting between the Allied and Associated Powers in Paris in March 1919, when it was agreed that in order to obviate the interchange of commemorative war medals, a medal should be instituted, called the Victory Medal, which should be of similar design for all the Allied and Associated countries, but that the conditions of award should be laid down by each Government. It was arranged that the obverse should represent a winged figure of Victory, full length in the middle of the medal, and full face; on the reverse an inscription "The Great War for Civilization" translated into different languages. The ribbon is identical for all countries and is red in the centre, with yellow, green and violet on either side shaded to form two rainbows.

The British issue authorized under Army Order 301 of 1919 conforms to the lines laid down at the Paris meeting and is of light bronze attached to the ribbon by a ring. When first manufactured, the medal was of dull bronze which proved unsatisfactory and the few which had already been distributed were recalled as far as possible, though doubtless a few still remain in private hands. It was granted to (1) the usual classes of military personnel who actually served on the establishment of a unit in certain specified theatres of war; (2) naval personnel who were mobilized or rendered approved service either at sea between midnight Aug. 4–5 1914 and midnight Nov. 11–12 1918, or on the establishment of a unit within a theatre of military operations; (3) personnel of the R.A.F. under similar conditions to the army and with the same additions as already specified for the British War Medal. No clasps were issued with this medal but a small bronze oak leaf is worn on the ribbon by personnel of the naval, military and air forces, who were mentioned in despatches by a commander in the field.

(5) *Territorial Force War Medal.*—Awarded by King George V. under Army Order 143 of 1920: granted to members of the Territorial Force or Territorial Force Nursing Service who volunteered for service overseas on or before Sept. 30 1914 and who, having been passed as physically fit for service overseas between Aug. 4 and Sept. 30 1914, rendered such service during the war 1914–8, provided that (*a*) they were serving with the Territorial Force before Aug. 4 1914, or (*b*) had completed a period of not less than four years' service with the Territorial Force before Aug. 4 1914 and rejoined that force on or before Sept. 30 1914. Members of the force who qualified for the award of the 1914 or 1914–5 stars were not eligible for this medal. Ribbon: broad yellow centre flanked on each side by a narrow green stripe; yellow edges.

(6) *Mercantile Marine War Medal.*—Awarded in 1919 by King George V. The medal is of bronze. Obverse: effigy of King George V. Reverse: a merchant steamer in a rough sea with a sailing-ship and a sinking submarine in the background. Ribbon: red and green with a central stripe of white; granted to personnel of the mercantile marine who qualified for the British War Medal, and who, in addition, served at sea on at least one voyage through a danger zone; also to those who, whilst serving at sea, were captured by the enemy or lost their lives through enemy action or were precluded by disablement through enemy action from further service at sea, before being able to complete their qualifying service for one of the medals.

### III.—War Medals of the United States, France, Italy and Japan

The war medals issued by the United States prior to 1910 are described at 18.18. The part played by the United States in the war against Germany in 1917–8 is commemorated by the American issue of the Victory Medal, which is granted to military personnel who served on active duty in the army of the United States at any time between April 6 1917 and Nov. 11 1918. The medal is also given to those who served in Siberia or European Russia subsequent to Nov. 11 1918. It is interesting to note that a series of battle clasps has been awarded for wearing on the ribbon of this medal, the United States being the only country which in 1921 sanctioned the issue of battle clasps. They are divided into two classes: (1) those given for certain major operations, and (2) those given for the occupation of a defensive sector; only one of the latter class is given to any one individual. A small bronze star is worn on the ribbon in service dress uniform for each major operation clasp. For each citation of an officer or man for gallantry in action not warranting the award of a Medal of Honor or a Distinguished Service Cross, a small silver star is worn on the ribbon.

In the number of commemorative war medals France comes second to Great Britain. They are as follows:—

(1) *St. Helena Medal.*—A bronze medal granted in 1857 to all survivors of the soldiers and sailors who took part in the wars lasting from 1792 to 1815. Obverse: effigy of Napoleon I. Reverse: the inscription "*Campagnes de 1792 à 1815. A ses compagnons de gloire, sa dernière pensée. Sainte Hélène, 5 Mai 1821.*" Ribbon: green with narrow red stripes.

(2) *Medal for Italy, 1859.*—A silver medal granted in 1859 to all who took part in the war against Austria in Italy in that year. Obverse: effigy of Napoleon III. Reverse: the names of the following battles: "Montebello," "Palestro," "Turbigo," "Magenta," "Marignan," "Solferino," and the words "*Campagne d'Italie, 1859.*" Ribbon: red with narrow white stripes.

(3) *China Medal 1861.*—A silver medal granted in 1861 to those who took part in the China expedition of 1860. Obverse: effigy of Napoleon III. Reverse: the names "Ta-kon," "Chang Kia Wan," "Pa-li-Kao," "Pe-King" and the legend "*Expédition de Chine 1860.*" Ribbon: yellow, with an inscription in Chinese characters.

(4) *Mexico Medal 1862–3.*—A silver medal awarded in 1863 to those who took part in the expedition to Mexico in 1862–3. Obverse: effigy of Napoleon III. Reverse: the names "Cumbres," "Cerro-Borrégo," "San Lorenzo," "Puebla," "Mexico" and the legend

**MECCA** (*see* 17.950), the great Holy City of Islam and capital of the Hejaz, had a resident pop. in 1916 estimated at about 70,000, including some 12,000 Indians. The annual pilgrimage brings normally at least 200,000 visitors to the city, of whom pilgrims from British India and the Malay States number as many as 25,000. Pilgrims from Egypt, by way of the quarantine station of Tor, numbered 14,500 in 1913, decreasing to 84 in 1914. During the early stages of the Arab revolt in 1916 the pilgrimages practically ceased from all parts; on their partial resumption in 1916–7 about 58,000 pilgrims arrived, mostly by way of Jidda, the Hejaz railway at that time being held by the Turks and the caravan roads across the peninsula by way of Jebel Shammar being unsafe. Communication between Mecca and Medina was interrupted from June 1916 until Jan. 1919 (when the Turks surrendered Medina), so that the visit to the Haram of the latter city—not strictly forming part of the pilgrimage—could not be performed during that period. On the capture of Mecca at the outbreak of the Arab revolt in 1916, the Turks opened fire with their artillery on the Great Mosque, and Sherif Huscin indicted them, in his proclamation dated 25 Sha'ban 1334 A.H., with having done material damage to the *kiswa* and Ka'ba.

The geographical position of Mecca was observed during war operations but was not fixed precisely, some further adjustments being necessary. The general aspect of the city had changed but little, though some modern buildings had sprung up; there were a number of stately residences, including the new king's palace of six storeys, and there is a considerable display of wealth. The sanitation of the city had made progress under the insistence of the King, and the water-supply, previously in a deplorable condition, had been improved. Much more strict hygienic precautions were reported to have been taken during pilgrimages. Some improvement had been effected in the Meccan postal and telegraphic arrangements, the Hejaz having become a member of the International Postal Union with its own issue of stamps, printed (1920) in Cairo. There was telegraphic communication between Mecca and Jidda, and between Mecca and Taif, the summer residence of the King 75 m. S.E. Before the war a weekly paper, *El Hejaz*, was published in Turkish and Arabic; a new weekly, *El Kibla*, was founded as the organ of the Government after the declaration of independence (1916), and a Hejaz agency was established at Cairo.

**MECHNIKOV, ILYA [ELIAS]** (1845–1916), Russian biologist, was born in the province of Kharkov May 15 1845. His father was an officer of the Imperial Guard and his mother was a Jewess. At the age of 17 he entered the Kharkov University and two years later went to Germany for further biological training. In 1867 he returned to Russia and took his degree in zoölogy both at Odessa and Petrograd, becoming professor ordinarius of zoölogy and comparative anatomy at Odessa. In 1882 he went to Messina and there began his studies into the nature and habits of microbes. Henceforth he devoted himself to pathological study and in 1888 went to Pasteur in Paris, who encouraged him and gave him a laboratory in the École Normale. He died in Paris July 16 1916.

See *Life* by his wife, Olga Mechnikov (1920), trans. by Mrs. R. L. Devonshire (1921).

**MEDALS AND DECORATIONS** (*see* 18.2; 15.860).—In the present article an account is given of British, American and other war medals and decorations created between 1910 and 1921, of new orders of knighthood considered as service decorations, and of changes in the insignia and the eligibility conditions of orders, decorations and medals existing in 1910.

### I.—British War Medals of the Period 1910–4

Before the war several new medals, as well as new issues of, and new clasps to, existing medals were authorized.

A new issue of the *African general service medal* was authorized in 1916 under Army Order 89 of 1916, bearing the effigy and titular legend of King George V. on the obverse. The conditions of award were similar to the old medal. Clasps: "East Africa 1913," "East Africa 1913–14," "East Africa 1914," "Shimber Berris 1914–15," "Nyasaland 1915," "Jubaland 1917–18," "East Africa 1918," "Somaliland 1920." Those already in possession of King Edward VII.'s medal received the bars only.

A new issue of the *India general service medal* of 1908 with the effigy of King George V. on the obverse, was made for later Indian frontier services. The clasp "Abor 1911–12" was authorized for the troops who took part in the Abor expedition of 1911–2 and the clasp "Afghanistan N.W. Frontier 1919" for service in the Afghan War of 1919.

The *Natal 1906 silver medal* was granted by the Natal Government in 1908 to all those who took part in suppressing the native revolt of 1906. Obverse: bust of King Edward VII. Reverse: an erect female figure representing Natal with the sword of justice in her right hand and a palm branch in the left, standing on a heap of native arms and supported by Britannia who holds the orb of empire in her left hand. In the background a group of natives with the sun bursting forth from behind the clouds. A clasp inscribed "1906" was issued with the medal. Ribbon: red with black edges.

The *Antarctic medal* was awarded to members of (1) Sir Ernest Shackleton's expedition of 1907 with clasp "Antarctic 1907–1909"; (2) Capt. R. F. Scott's expedition with clasp "Antarctic 1910–1913"; (3) the Mawson expedition 1912 with clasp "Antarctic 1912"; (4) Sir Ernest Shackleton's Imperial trans-Antarctic expedition of 1914–6 with clasp "Antarctic 1914–1916." The medal in bronze was granted to the crews of various relief ships at different dates, and is a separate decoration, which can be held in addition to the silver medal.

In 1915 a *naval general service medal* was awarded by King George V. for service in minor naval operations, whether in the nature of belligerency or police, of sufficient importance to justify the award of a medal where no other medal would be appropriate. Obverse: the head of King George V. in naval uniform. Reverse: a representation of Britannia and two sea-horses travelling through the sea. A clasp, "Persian Gulf 1909–1914," was authorized when this medal was established, for issue to officers and men of His Majesty's ships engaged in the suppression of arms traffic in the Persian Gulf. Ribbon: white with crimson borders and two crimson stripes.

A new *Khedive's Sudan medal*, having effect from 1910, was awarded by the Khedive in 1911. Obverse: the cypher of the Khedive and the date in Arabic. Reverse: a lion with forepaws resting upon a panel bearing the word "Sudan." Below, an oval native shield and spears. In the background the river Nile with palm trees and the rising sun. Clasps: "Atwot," "S. Kordofan 1910," "Sudan 1912," "Zeraf 1913–14," "Mongalla 1915–16," "Darfur 1916," "Fasher," "Lau-Nuer," "Atwot 1918." The medal without bar was given to troops engaged in operations in the Matong Mts., Mongalla, in 1916; and at various times the medal in bronze without the bar was awarded to certain classes of civilian followers.

### II.—British World War Medals

The issue of medals commemorating service in the World War is naturally the widest ever recorded. The long duration of the war, the fact that almost every part of the civilized world was involved in it, the great numbers of men and women taken into war service in different capacities, and to some extent popular feeling at different periods during and after the war, resulted in somewhat different principles from those of the past being observed in rewarding war service, all the more so as the conventional idea of "campaign" and "battle" ceased in a great measure to afford a guide in laying down regulations. Thus, in addition to the British general services war medal common to all who served in a theatre of war, the Allied and Associated Powers agreed upon a common medal to commemorate the united effort, and, within the British forces, the characteristic services of the original Expeditionary Force, of the men of the Territorial Force who had undertaken obligations and training in peace, of the war volunteers who formed the new armies of 1914–5 and of the mercantile marine were each recognized by the grant, under certain conditions, of a particular star or medal.

The stars and medals awarded and the general conditions qualifying for award are as follows:—

(1) *1914 Star.*—Awarded by King George V. under Army Order 350 of 1917. This decoration is a four-pointed star in bright bronze on which are superimposed two crossed swords and a laurel wreath. In the centre a scroll with the inscription "Aug. 1914 Nov." Ribbon: red, white and blue, shaded and watered. Granted to all officers, warrant officers, non-commissioned officers and men of the British and Indian forces, including civilian medical practitioners, nursing sisters, nurses and others employed with military hospitals,

The *Most Excellent Order of the British Empire* was instituted in June 1917 to reward war services in all capacities, military and civil. In 1918, in order to mark the distinction between awards for civilian and military services, a military division of the order was created. Broadly speaking, it may be said that the military division is conferred on military personnel for distinguished service other than gallantry in action during war. The order is divided into five classes. The badge of the first, second, third and fourth classes consists of a silver-gilt cross, that of the fifth class being executed in silver. Members of the first and second classes wear a star on the left breast in addition. A silver medal of the order can also be awarded to those persons, not being members of the order, whose services to the Empire warrant such recognition. The ribbon is plain purple, that of the military division being distinguished by a narrow red line down the centre.

The *Distinguished Service Medal.*—Established in Oct. 1914 by King George V. Obverse: the effigy of King George V. in naval uniform. Reverse: the words "For Distinguished Service," surmounted by a crown and encircled by a wreath of laurel. Ribbon: blue with two broad white stripes in the centre. Awarded to petty officers and men of the Royal Navy, and non-commissioned officers and men of the Royal Marines and all other persons holding corresponding positions in the naval forces who may at any time show themselves to the fore in action and set an example of bravery and resource under fire, but without performing acts of such preëminent bravery as would render them eligible for the Conspicuous Gallantry Medal. Bars are awarded for further services.

The *Military Cross.*—Instituted in Dec. 1914 by royal warrant. It consists of an ornamental silver cross, on each arm of which is an imperial crown with the imperial cypher "G.R.I." in the centre. Bars are awarded for further services. It is awarded to military officers below the rank of major and to warrant officers in the army, Indian army, or Colonial forces. During the first two years after its institution, this decoration was not confined to service in action, but was also given in recognition of distinguished service at the base or with the administrative branches of the army in theatres of war. After 1916, however, it was confined to those whose services were thought worthy of recognition while under the fire of the enemy. Ribbon: white watered silk with a purple centre.

The *Military Medal.*—Instituted in March 1916 for award to non-commissioned officers and men of the army for individual or associated acts of bravery in the field. The medal is of silver. Obverse: the royal effigy. Reverse: the words "For bravery in the Field" encircled by a wreath and surmounted by the royal cypher and crown. Ribbon: dark blue having in the centre three white and two crimson stripes alternating. Bars are awarded for further acts of bravery in action. The award was subsequently extended to warrant officers and to women, the qualification for the last named being "For bravery and devotion under fire."

The *Distinguished Flying Cross.*—Instituted in 1918 for award to officers and warrant officers of the R.A.F. for acts of valour, courage, or devotion to duty performed while flying in active operations against the enemy. The cross is of silver, terminated in the horizontal and base bars with bombs, the upper bar terminating with a rose, surmounted by another cross composed of aeroplane propellers, charged in the centre with a roundel within a wreath of laurels a rose winged ensigned by an imperial crown, thereon the letters R.A.F. On the reverse the royal cypher above the date 1918, the whole attached to the clasp and ribbon by two stripes one-eighth of an inch wide running at an angle of 45° from left to right. Bars are awarded for further services.

The *Distinguished Flying Medal.*—Instituted in 1918 for award under similar conditions to the Distinguished Flying Cross, to non-commissioned officers and men of the R.A.F. The medal is of silver, oval-shaped, bearing on the obverse the royal effigy and on the reverse, within a wreath of laurel, a representation of Athena Nike seated on an aeroplane, a hawk rising from her right arm above the words "For Courage." The whole ensigned by a bomb attached to the clasp and ribbon by two wings. Ribbon: violet and white in alternate diagonal stripes one-sixteenth of an inch wide running at an angle of 45° from left to right. Bars are also awarded.

The *Air Force Cross.*—Instituted in 1918 for award to officers and warrant officers of the R.A.F. for acts of valour, courage or devotion to duty whilst flying, though not in active operations against the enemy, and also to individuals not belonging to the R.A.F. (whether naval, military or civil) who render distinguished service to aviation in actual flying. The cross is of silver and consists of a thunderbolt in the form of a cross, the arms conjoined by wings, the base bar terminating with a bomb, surmounted by another cross composed of aeroplane propellers, the four ends enscribed with the letters G.V.R.I. In the centre a roundel, thereon a representation of Hermes mounted on a hawk in flight bestowing a wreath. Reverse: the royal cypher above the date 1918. The whole ensigned by an imperial crown attached to the clasp and ribbon by two sprigs of laurel. Ribbon: red and white in alternate diagonal stripes one-eighth of an inch wide, running at an angle of 45° from left to right. Bars are awarded for further services.

The *Air Force Medal.*—Instituted in 1918 for award, under similar conditions to the Air Force Cross, to non-commissioned officers and men of the R.A.F. and to individuals not belonging to that force (whether naval, military or civil) who render distinguished service to aviation in actual flying. The medal is of silver, oval-shaped. Obverse: the royal effigy. Reverse: within a wreath of laurel a representation of Hermes mounted on a hawk in flight bestowing a wreath. The whole ensigned by a bomb attached to the clasp and ribbon by two wings. Ribbon: red and white in alternate diagonal stripes one-sixteenth of an inch wide running at an angle of 45° from left to right. Bars are awarded for further services.

The *Military Star of the Sultan Fouad.*—Instituted in 1919 for award to officers of the Egyptian army who are mentioned in despatches for merit or for distinguished services on the field of battle or before the enemy. It consists of a five-rayed star suspended from a straight clasp. The obverse is enamelled white, bordered gilt, with a gilt fillet in the centre of each ray. The centre is enamelled red and blue, upon which appears a garland of laurel, surrounding two crossed swords, and surmounted by the Sultan's crown, all in relief and gilt. The reverse is similar, but has in the centre a blue circle surrounded by a gold chaplet bearing in Arabic the inscription "The Military Star of the Sultan Fouad." Bars are awarded for further services. The ribbon is of five equal stripes of blue, chamois, black, chamois, blue.

## V.—American and French Personal Decorations

The World War of 1917–8 caused the institution in the United States of four new service decorations in addition to the Congressional Medal of Honor reserved for acts of the highest bravery.

(1) *Distinguished Service Cross. Army.*—Instituted on Jan. 12 1918 for award to military personnel, including women, who distinguish themselves by extraordinary heroism in connexion with military operations against an armed enemy of the United States under circumstances which do not justify the award of the Medal of Honor. The cross is of bronze surcharged with the American spread eagle, and hangs from a blue ribbon with narrow white and red stripes at either edge. Beneath the eagle is a scroll bearing the words "For Valor." A bronze oak leaf is worn on the ribbon to denote a second award.

(2) *Distinguished Service Medal. Army.*—Instituted on Jan. 12 1918 for award to military personnel, including women, for exceptionally meritorious service to the Government in duty of great responsibility in time of war, or in connexion with military operations against an armed enemy of the United States. The medal is of bronze and bears on the obverse the coat-of-arms of the United States surrounded by a circular ribbon of blue enamel bearing the words "For Distinguished Service" and the date "MCMXVIII." Ribbon: scarlet, in the centre a broad stripe of white, with a narrow stripe of dark blue on each side of it. Further acts of bravery are denoted by a bronze oak leaf worn on the ribbon.

(3) *Distinguished Service Medal. Navy.*—Awarded to naval personnel who, since April 6 1917, distinguished themselves by exceptionally meritorious service to the Government in a duty of great responsibility. The medal is of bronze. Obverse: a foul anchor, placed perpendicularly; on the right a sprig of laurel. The words "Distinguished Service" in raised letters round the top circumference; in the background a squadron of ships with the sun rising over the horizon. Reverse: a plaque for the name of the recipient superimposed upon a sprig of laurel. The clasp for suspension from the ribbon shows the American eagle standing upon a scroll with the date "1917–18." Ribbon: blue with a central stripe of yellow. An emblem is worn on the ribbon to denote a second award. Enlisted or enrolled personnel who receive the medal are granted a monthly increase in pay of two dollars.

(4) *Navy Cross.*—Awarded to naval personnel for extraordinary heroism or distinguished service since April 6 1917 in cases not justifying the award of either the Medal of Honor or the Distinguished Service Medal. The decoration is a bronze cross patée convexed with points of laurel at the junction of the limbs. In the centre are crossed foul anchors and the letters "U.S.N." Ribbon: blue with a central narrow stripe of white. An emblem is worn on the ribbon to denote a second award. Enlisted or enrolled personnel who receive the cross are granted $2 a month increase in pay.

The principal personal decorations in France are as follows:—

The *Médaille Militaire.*—Established in 1852. It is only awarded to general officers in command of armies and to non-commissioned officers and men of the army and navy who specially distinguished themselves in action. The decoration is of rather complicated design. In the centre of the obverse is the gilt female head of the Republic on a roughened gilt ground, surrounded by a narrow band of blue enamel bearing the words "*République Française 1870*" in gilt letters. On the reverse "*Valeur et Discipline.*" Above the medal is a trophy of arms. Ribbon: orange with green edges.

The *Legion of Honour* is dealt with in 15.863.

The *Croix de Guerre.*—Established in 1915 to commemorate individual mentions in despatches during the war 1914–8. The cross was awarded to soldiers or sailors of all ranks, including officers, who were mentioned in orders of the day for an individual feat of arms. The different classes of orders (regimental, divisional,

etc.) for which the cross was awarded are denoted by a bronze laurel branch or different kinds of stars attached to the ribbon, which is green with narrow red stripes.

### VI.—Personal Decorations of Other Countries

The revolution in Russia, Germany and Austria-Hungary closed the history of many of the older orders; but both those still existing and those which have ceased to exist were given largely for war services during the World War, and they are here briefly dealt with as decorations.

*Italy.*—The most important of the Italian service orders and decorations are as follows:—

(1) Medals for military valour.—These medals are awarded for special individual acts of bravery to both officers and men of the army and navy. The medals are of three classes, gold, silver and bronze, but the first is rare.

(2) *Cross for merit in war.*—A bronze cross bearing on one side the words "*Merito di Guerra*" surmounted by the royal crown and initials. Reverse: a star surrounded by rays. Awarded to those whose conduct has been meritorious for some considerable period during war, but who have not performed some exceptionally gallant action deserving of the medals for military valour.

(3) *Military Order of Savoy.*—Instituted in 1815, consisting of five classes. Awarded for specially distinguished services in war and for exceptional services in times of peace. The decoration consists of a cross resting on a wreath of laurel.

(4) *Order of the Crown of Italy.*—Established in 1868 to commemorate the annexation of Venetia and the unity of Italy. There are five classes. The badge consists of a gold cross patée convexed enamelled white, edged gold, with gold love knots between the limbs. In the centre on a blue enamelled plaque, edged gold, is a golden representation of the Iron Crown.

(5) *Order of Saint Maurice and Saint Lasarus.*—Founded in 1434. There are five classes. The badge consists of a Maltese cross, placed saltirewise, vert edged gold, with gold knobs on the points for St. Lazarus; surmounted by a cross botoné enamelled white, edged gold, for St. Maurice. The badge of the first four classes has the royal crown above it.

*Russia.*—(1) The *Order of St. George*, probably the best-known of all Russian decorations, was founded in 1769 by the Empress Catherine II. for rewarding distinguished bravery in action. It consists of a gold, white enamelled cross, patée, with, in the centre, a representation of St. George fighting the dragon. There are four different grades and the ribbon is orange and black. (2) *Order of St. Anne* (three classes and various medals); the cross is of crimson enamel and the ribbon carmine with narrow gold edges. (3) *Order of St. Stanislas* (three classes); cross, ribbon red and white. (4) *St. Vladimir* (four classes); cross, black enamel, ribbon red and black.

*Serbia.*—(1) *Order of the White Eagle.* Instituted in 1883, consisting of five classes: knight grand cross, grand officer, commander, officer and companion. The badge consists of a gold double-headed eagle surmounted by a crown. (2) *Order of St. Sava.* Instituted in 1883, consisting of five classes. Awarded principally in recognition of valuable sanitary and medical services with the army. (3) Medals for bravery. These are in gold and silver according to class.

*Greece.*—(1) *Order of the Redeemer.* Instituted in 1829, consisting of five classes: grand cross, grand officer, commander, officer and knight. (2) *Military Cross.* This is the highest award for services in the field. It was instituted in 1917 and consists of three classes.

*Rumania.*—(1) *Order of the Star of Rumania.* Instituted in 1877 to commemorate the participation of Rumania in the Russo-Turkish War. There are five classes: knights grand cross, knights commanders, commanders, officers and chevaliers. (2) *Order of the Crown.* Instituted in 1881. There are five classes as above.

*Belgium.*—(1) *Order of the Crown of Belgium.* Instituted in 1897 for honouring those who distinguish themselves in artistic, literary or scientific work; in industrial or commercial activity or by their devotion in works of African civilization. There are five classes of the order and a medal. (2) *Order of Leopold.* Instituted in 1832, consisting of five classes. This order is sometimes conferred upon military officers for service in the field. (3) *Croix de Guerre.* Instituted in 1915 for award to those who are mentioned in despatches and for acts of courage, devotion and valour on the field of battle.

*Japan.*—The principal Japanese military decoration is *The Order of the Golden Kite*, instituted in 1891 and awarded solely for acts of very distinguished bravery performed in action by officers and men of the army and navy. There are seven classes. It consists of an eight-pointed star edged with gold or silver according to class, upon which is placed a species of St. Andrew's cross in blue enamel. On the top of the decoration is a golden kite with wings spread. Ribbon: green, with a white stripe at each edge. The chief remaining decorations are *The Order of the Rising Sun* and *The Order of the Sacred Treasure* (women), but these are not confined to naval and military persons.

*Germany.*—While the orders of the various states (which were numerous) were conferred on individuals for war service, the principal decorations were, with one exception, Prussian decorations conferred by the emperor, in his capacity as king of Prussia, upon Germans of all federal states. These Prussian decorations which became in effect German were:—the order *Pour le Mérite* and the *Iron Cross*. The ribbon of both is black with white edging (the Prussian colours). The Iron Cross of the higher class was worn without a ribbon. One award was made of the *Iron Cross with gold star*, perhaps the rarest of all military decorations. This was to Field-Marshal von Hindenburg, and the only previous recipient had been Prince Blücher. Awards of the Iron Cross of 1914 were not made to those who held the Iron Cross of 1870; who received a bar instead. A decoration given for auxiliary war services, both to military and to civil personnel, was the *Verdienstkreuz für Kriegshilfe*. This, which though Prussian was regarded from the outset as purely a German decoration, is a cross in silver-grey metal with a ribbon of the German national colours—silver, with narrow black stripes and red and black edges. (R. E. F.)

**MEDICAL EDUCATION** (*see* 18.23).—To the reformer's zeal an impetus was lent by the World War in various fields, and in the domain of medical education it was still by no means easy in 1921 to estimate how far the changes that had been effected in the few preceding years had the quality of permanence. Of those changes two overshadow the rest, namely the introduction in 1920 of the Clinical Unit system into England, and the admission of women students to a number of London medical schools, which in that respect came into line with the practice of the great majority of provincial universities. Though these events were actually the outcome of many years of preparation, yet they partook more of the nature of tentative experiments than changes effected and wearing an air of finality. There was a desire to test in practice views long rooted in theory.

*Great Britain.*—The decision of some of the London schools to admit women students was largely in the nature of an emergency measure planned to meet the exigencies of the moment. These schools, deprived by the war of most of their male students, were led to look elsewhere for recruits. The experiment was first tried in a very tentative way by St. George's hospital, but early in 1916 St. Mary's hospital was thrown open to both sexes. In 1921 the London hospital, St. Mary's, University College hospital, King's College hospital, Charing Cross hospital, Westminster hospital and St. George's hospital all admitted women students. Some of these schools regarded this innovation as an experiment while others were committed to the policy of coeducation.

The Clinical Unit organization undoubtedly constitutes a fundamental modification of the system of medical education, which, arising out of the apprenticeship system, had come to be accepted as a sound and practical course of instruction. In the early days of the medical schools all the teaching, including chemistry, physics and biology, was carried out by the medical and surgical staff. The first subject to break away was chemistry, and in 1870–80 many of the schools engaged chemists to train their students in this subject. Later physics, and later still biology, followed suit. During 1900–20 the same change occurred in the teaching of physiology and anatomy, so that by 1921 the preliminary and intermediate subjects of the curriculum were taught by workers who devoted all their time to that purpose. This change has spread to the later subjects of the medical course, in response to the growing demands which developments in knowledge and technique make upon the time and equipment of teachers. In these proposals to create units there is therefore no rude break with tradition, but rather a step forward in the evolution of medical education forming a logical outcome of the whole trend of contemporary medical teaching and an inevitable sequel to the advances that have taken place in medicine and the allied sciences.

In 1908 grants in aid of medical education were made for the first time by the Board of Education, and with their general acceptance the autonomy of the schools, based on their financial independence, disappeared. It was clear from the first that schools which received a grant must submit to the policy of the Board of Education, and it was on that bedrock fact that the Royal Commission on University Education in London built. The report, published in 1913, indorsed the views of Mr. Abraham Flexner, set forth in his survey of "Medical Education in Europe" (1912), and was in substance, so far as it concerned medical education, an argument for the creation of clinical

units. In England, in the provinces, and in Scotland the universities had had for many years the germ and often the essentials of clinical units, but in London, with its various medical schools loosely bound to a central university, this was not the case. But though the Board of Education were now in a position to carry out their policy, no further steps were taken, owing to the outbreak of war, until 1920. In that year clinical units in medicine and surgery were created at St. Bartholomew's hospital, St. Thomas' hospital, the London hospital and University College hospital. The Board of Education undertook, through the University Grants Committee, to defray three-quarters of the cost, the medical school furnishing the other quarter. At two of these schools the directors of the units were expected to devote all their time to the duties of their office and were debarred from private practice. Early in 1921 the London School of Medicine for Women applied for and secured recognition of a unit in gynaecology and obstetrics, the first appointment to be made in that branch of the curriculum, while a little later units in medicine and surgery were created and recognized at St. Mary's hospital, under the same conditions and financial clauses that governed the grants in aid of the first four schools. Subsequently the appointment of the directors was vested in the Senate of the London University, who became not only responsible for the selection of the professoriat, but required to be satisfied that he has an adequate number of assistants, a proper and effective out-patient department, that he is allotted the control of a sufficient number of beds, and that the laboratory accommodation allocated to the unit for research and pathological work is satisfactory.

The unit system is designed to secure that the latest advances in science affecting medicine should be continually brought to the teaching of the clinical subjects. To achieve that end the teachers must themselves actively engage in scientific research, and should be provided with proper equipment, an adequate number of assistants and sufficient leisure to prosecute researches. It is hoped to link up laboratory workers and clinicians and generally to introduce organization into clinical teaching, so that in the issue the defects of the older régime may be removed while its obvious merits are preserved.

A hopeful feature in the story of British medical education during 1910–20 was to be found in the provision of additional facilities for research, for which the Clinical Unit system and the Medical Research Council were jointly responsible. Together they have provided paid posts for the best of the younger men, in which during the waiting years the more hopeful may find opportunities of research and scientific activity. Apart from the higher standard that may reasonably be expected of candidates who are elected to hospital appointments after such opportunities, research and all that comes of it should benefit by a constant stream of recruits drawn from the more promising elements of each year.

The possibilities of clinical instruction that lie latent in the Poor Law infirmaries have long been known, but the difficulties in the way of throwing their wards open to students had proved insuperable until early in 1920 they were overcome by St. Mary's hospital. This hospital entered into an agreement with the Paddington Board of Guardians under the terms of which students belonging to that medical school are allowed to work in the wards of the infirmary. The hospital furnishes bacteriological and pathological services, and a consulting staff who visit the infirmary on appointed days every week, and who hold regular classes in the wards. The significance of such a step becomes plain since there are in London approximately three infirmary beds to every bed in voluntary hospitals with teaching schools attached. In this connexion the Voluntary Hospitals Committee, appointed in Jan. 1921, issued in June a report in which they put on record that they deemed it unfortunate that these institutions should hardly be used at all in the training of medical students, and recommended the extension of the arrangements existing between St. Mary's hospital and Paddington infirmary to other hospitals and infirmaries. If this were carried out, not only would the clinical material available for the purposes of undergraduate instruction be greatly increased, but a class of case would be seen by students at these institutions that is not admitted to the voluntary hospitals, so that a gap that had hitherto existed in the student's education would be filled.

With a search for new facilities for clinical study has gone a growing desire to remove from the student's path obstacles that appear to interfere at present with the true educational purpose of his training. Dissatisfaction with the existing examination system, which is never altogether absent, came to a head early in 1921 when a motion was brought before the Faculty of Medicine of the university of London asking for permission to hold internal examinations at certain medical schools, and that one of the two examiners should be the students' teacher. While there was point in many of the criticisms of the existing system, the feeling of the Faculty was that examinations should not be abolished. nor so modified that they no longer provided adequate tests for granting a qualification which carries with it the right to practice, before an efficient substitute had been found for them, and the motion before the Faculty was accordingly defeated by a large majority. It was felt however that this was not the last word, and many held that a reform of the present examination system was overdue, that in its present condition that system exercised a baneful influence on the true educational purposes underlying the curriculum. On the other hand it appeared probable that many of the disadvantages laid at the door of the examination system were in fact due to the overcrowding of the curriculum. Subjects continue to be added to this, while much that is out of date or of little educational value is allowed to remain in the syllabus. While no sustained attempt has been made to unload the unwieldy vehicle which at present contains what the student is expected to carry away with him, there has been a growing tendency to consider and pave the way for ultimate reform, and these matters were in 1921 engaging the attention of the General Medical Council.

With regard to postgraduate instruction, the defects of the existing arrangements had been exposed and opinion was ripe for action. There was a consensus of opinion that undergraduate and postgraduate instruction cannot be combined at the same school, and that the facilities provided by hospitals in London not attached to medical schools were totally inadequate. The way had therefore been prepared for the report of the Committee on Postgraduate Instruction, of which Lord Athlone was chairman. In substance that report (June 1921) recommended that one of the London general hospitals, with at least 300 beds and proper modern equipment, should be set aside as a postgraduate centre. (C. M. Wi.)

*United States.*—In 1910 there were in existence in America approximately 150 medical schools, mostly in fact, if not in form, private ventures; even the few schools of high grade possessed meagre endowment and inadequate facilities. By a process of natural selection, the number of schools was rapidly reduced, having fallen in 1920 to approximately 85, and there were grounds for the belief that this number would in the near future be still further reduced. The organization, endowment, and facilities for instruction showed a notable advance. In 1910 few medical schools actually controlled the hospitals in which their teaching was done. Subsequently there was a distinct tendency to give the university medical schools exclusive and adequate control of hospital facilities for clinical teaching and research. Harvard, Yale, Washington, and other universities thus came into much more intimate relations with the hospitals in which the clinical staff teaches. The city of Cincinnati built one of the finest public hospitals in the United States, and amended the city charter so as to give the university of Cincinnati (a municipal institution) complete control of the hospital for the purposes of its medical school.

On the financial side public opinion was brought to realize that the university school of medicine is an expensive enterprise, for which large investments must be made by the public in both facilities and endowment. Mr. John D. Rockefeller gave the General Education Board approximately $35,000,000 to be used primarily for the purpose of coöperating with institutions in raising larger sums for the development of their medical schools, and the late Mr. Joseph R. DeLamar gave $5,000,000 each to the medical departments of Harvard, Columbia, and Johns Hopkins. Upwards of $10,000,000 was raised for the establishment of a new medical department at the university of Rochester, Rochester, N.Y., and $8,000,000 for the reorganization of the medical department of Vanderbilt University, Nashville, Tennessee. Many other endowed institutions also procured considerable sums for improved laboratory and teaching facilities. The current budgets of the state universities were similarly increased so as to enable the institutions to go forward in developing their medical schools correspondingly.

In respect to organization the main change in the decade was the introduction of the full-time plan corresponding to the English unit system in the teaching of the clinical subjects. The aim and purpose of this movement are the same in both countries, but in neither had sufficient time elapsed up to 1921 to allow a final verdict to be passed on the merits of the system. The complete satisfaction of the Johns Hopkins Medical School

in the working of this plan is shown by the fact that the system, which originally included medicine, surgery, and pediatrics, was in 1920 extended so as to take in gynaecology and obstetrics. The system was also adopted in the main clinical branches by the medical departments of Washington University (St. Louis), Yale University, Vanderbilt University, university of Chicago, and the university of Rochester.

*China.*—Through a subsidiary board (the China Medical Board) the Rockefeller Foundation of New York has established in China a modern medical school. The Rockefeller Foundation has furnished funds amounting to $8,000,000 to build and equip the Pekin Union Medical College, and in addition it was in 1921 supporting the institution on the basis of a budget for the year amounting to $500,000. The institution furnishes two years of pre-medical work, and intended to develop a four-year medical course. In addition to the undergraduate training of Chinese physicians, it will provide graduate training, offers short courses for physicians in the field, and endeavours to extend in the Orient a popular knowledge of medicine and public health. The China Medical Board also aids four other medical schools in China carried on by other organizations.

*Belgium.*—The university of Brussels had in 1921 planned a complete reorganization of its medical department. The city, the State, and the university coöperated in maturing plans for a modern teaching hospital, and new, well-equipped laboratories on a single site. Approximately 100,000,000 francs was needed to finance the enterprise, of which 40,000,000 was pledged by the Rockefeller Foundation. (A. Fx.)

*Canada.*—There were in Canada eight medical colleges in 1921 giving a complete course leading to the degree in medicine. In every case the college forms a part of a university, and most of them are to be found in the eastern provinces. In the West only one university (Manitoba) gives a complete medical course, though the university of Alberta offers the first three years of a six-year course, her students as a rule finishing their work in one of the eastern universities. During the years 1910–21 there was a steady advance in standards in the medical curriculum. The four-year course, which followed a minimum entrance requirement of Junior matriculation, was first increased to five years and later to six years in most of the schools. The five-year course was planned partly to meet the demand for increased instruction in the so-called pre-medical sciences and partly to give more time for the clinical branches. Where this course is in force the first year is devoted to biology, chemistry and physics, the second and third years to anatomy, physiology, histology and embryology, physiological chemistry, pharmacology, pathology and bacteriology, the fourth and fifth years practically to the clinical subjects, namely, medicine, surgery, obstetrics and gynaecology with their various special branches. The increase to six years gives more time to the clinical subjects, and in addition enables the Faculties of at least some of the schools to offer certain electives or options. This latter plan gives to the better-class student an opportunity to graduate with more than the minimum requirements for the degree of M.D. The six-year course is given in certain of the schools entirely within the medical department, although the curriculum includes certain courses to be taken in the other Faculties. Other schools plan to require two years as a pre-medical requirement to the four-year course. These two years may be taken in any of the standard universities and must include biology, chemistry and physics. At least one school was in 1921 planning to add to the four-year course a hospital year, which must be taken before graduation. In most of the medical schools the regular course in medicine leads to the degree of M.D. or to the degree of M.D.-C.M. One school gives the degree of M.B. at the close of the regular course, with the M.D. one year later on presentation of a satisfactory thesis. The combined degrees of B.A.-M.D. or B.Sc.-M.D. may be obtained in practically all the schools in seven or eight years. A special degree of B.Sc. (Med.) may be obtained in two of the schools by a year of special work at any time after the third year of the regular course in medicine. (J. W. S.)

**MEDICAL ENTOMOLOGY.**—What used to be called comprehensively "economic" entomology is now more conveniently divided into two distinct branches—economic (*see* ECONOMIC ENTOMOLOGY) and medical. In its medical bearings the scope of entomology comprehends not insects only but arthropoda of every kind directly hurtful to health. Until about 1880 the fact that many arthropoda can bite and sting, and that some are troublesome parasites of man, was not thought important enough in medical practice to require special attention in their entomological aspect; but when in the last quarter of the 19th century the startling announcement was made that one of the commonest diseases of the tropics is propagated by a bloodsucking insect it was soon realized that light might be thrown on many obscure problems in the causation of infective disease by a precise knowledge of the arthropoda that come into contact with man. This illuminating doctrine was first opened out in 1879, when Sir Patrick Manson, at that time a plain medical practitioner in China, published the essential parts of an experimental proof that the parasitic worm which causes the disfiguring febrile and subfebrile diseases known collectively as filariasis is communicated from man to man by a common house-haunting mosquito. It is true that long before 1879 seasonal fevers in several parts of the world had been ascribed, not only in popular tradition but also by plausible argument, to the bites of insects, but these vague glimmerings of the truth had not been regarded very seriously, and Manson was the first to demonstrate, by verifiable experiment, that in such cases the insect plays an indispensable triple part, namely, (1) after infecting itself with parasites responsible for the fever by imbibing the blood of a human being infected with them, (2) to provide in its own organs and tissues the appropriate medium for the growth and development of the parasites so absorbed and finally (3) to carry the parasites so fostered to fresh human victims. The precise manner in which the filariated mosquito passes on its acquired infection was not settled by Manson, but his wonderful discovery originated that new branch of study where a full and exact knowledge of all the arthropoda that touch man in his person, his dwellings, and his food and drink, finds, as Medical Entomology, a rational application in the control of disease.

*Subject-matter.*—In dealing with the subject-matter of Medical Entomology it is convenient rather than severely logical to group the arthropoda inimical to health in five categories, according to the nature, the direct effects and the after consequences of their results, namely as (1) simply parasitic, (2) simply predaceous, (3) specifically infective, (4) contaminative and (5) venomous, the third and fourth being far the most important.

*Simple Parasites.*—Here are included all those arthropod parasites that are hurtful solely by their presence on or in the body and not by any subsequently disclosed effects. Such are the itch-mites (*Sarcoptes*) specific to man, and the numerous food-mites, animal-mites, bird-mites, insect-mites, harvest-mites, etc., which in certain circumstances or at particular seasons may attack man, though not normally parasitic on him or in every case parasitic at all in normal habit. Though they usually attack the epidermis these mites may get into the bowel, or the lung, or the bladder. Such also are those muscoid flies which in their maggot stage are constantly and entirely dependent on warm-blooded animals for their existence: two such species of maggots are notorious subcutaneous parasites of man, namely the "macaw worm" (*Dermatobia hominis*) in tropical America, and the "tumbu" (*Cordylobia anthropophaga*) in tropical Africa. Bluebottles, flesh-flies and other domestic flies, which normally deposit their eggs or larval progeny in decomposing meat and carrion, may be attracted for this purpose to foul and neglected wounds, or to the eyes, nostrils and other natural orifices of unclean or incapable humanity, with dire results: the "screw-worm" flies (*Cochliomyia* in America and *Chrysomyia* in India) are said to be particularly prone to this deplorably mistaken instinct. Living maggots of many species of flies may find a congenial abode in the human bowel, as also may larvae of other orders of insects. Other simple parasites of man are the "Chigger" flea (*Dermatophilus penetrans*) common in certain parts of tropical America and Africa, the pregnant female of which embeds herself in the skin; and the "Congo floor-maggot" (*Auchmeromyia*) of tropical Africa, a maggot which infests native huts like a bedbug and sucks the blood of sleeping people, though the parent fly is harmless. An abnormal and misdirected parasite that, in places where large snakes are numerous, may get encysted in the human viscera, is the larva of the extraordinary wormlike arthropod *Porocephalus*, the adult of which is a bloodthirsty inhabitant of the lungs of snakes.

*Predaceous Arthropoda.*—To this category may be relegated a miscellany of blood-sucking insects, etc., the bite of which may be painful or may even cause severe inflammation, but is not known to be followed by any specific infection apart from a chance of ordinary septic contamination as a result of scratching. Though there are times and places when these insects may be an intolerable burden to travellers or to country folk, they have no preference for human blood and no particular affection for houses. They cannot therefore be regarded as a standing menace to the public health, although they may be treated with a reasonable amount of suspicion, because some of them are known to spread specific infections among domestic stock, and also because they may be chance mechanical carriers of some individual contamination, or may have parasites proper to themselves which might possibly under certain circumstances be transferred to man. This suspicious assemblage includes many species of mosquitos and gadflies, a lot of midges (*Simulium*, *Psychoda*, *Culicoides*, etc.), and numerous species of muscoid flies (*Stomoxys*, *Haematobia*, *Lyperosia*, etc.) that usually feed on cattle; also various flies (*Leptidae*, *Asilidae*, etc.) that normally feed on

other insects; and some kinds of plant bugs and leaf hoppers in which the thirst for blood is an aberration.

*Specifically Infective Arthropoda.*—The parasitic and predaceous forms so far enumerated are for the most part obnoxious rather than greatly dangerous, and the trouble they cause does not linger after their disappearance; but we have now to deal with an assortment of parasitic and predaceous arthropoda, which, by propagating micro-parasites pathogenic to man, cause ill effects that outweigh and outlast any direct damage that they themselves can inflict. Such arthropoda, having severally a definite biological association with a particular disease, and being specific "nurses" or intermediary hosts of the parasite actually causing the disease, are known as "carriers" or "vectors." Their function is beautifully exemplified in Sir Ronald Ross's great discovery of the way by which the parasites of malarial fevers are maintained and disseminated—a discovery which must here have precedence, not that it was historically the first of its kind, but because it was originally presented in a complete form and best illustrates the emergence of Medical Entomology as a distinct study.

Independently of Ross's investigations, it was known that the parasites multiplied periodically by non-sexual fission (*schisogony*) in the blood of malaria patients, and that they also gave issue to prospectively sexual bodies (*gametocytes*), male and female, which did not become ripe until after the blood had been withdrawn from the blood vessels; and it had been discovered by MacCallum that when the ripe sexual elements (*gametes*) did become revealed in the drawn blood the males and females paired together to form united couples or *zygotes;* it was known, in short, that while the parasites multiply non-sexually in the blood of the individual human sufferer, the process by which they are maintained as specific parasites of the human race must take place, somehow, outside the individual human host. Manson inferred, from his own earlier investigations of the filaria parasite, that it must be in the interior of some blood-sucking arthropod, probably a mosquito, and the arduous proof of this hypothesis was unravelled by Ross. Ross followed the parasites from the vertebrate host into the stomach of the mosquito, and thence into the insect's stomach wall, where the zygotes encyst and establish themselves as parasitic *oöcysts.* Under favourable conditions the oöcysts increase in size by the internal proliferation of their contents, and in about ten days ripen into *sporocysts,* full of minute spore elements or *sporozoites.* By the rupture of the sporocysts the sporozoites escape into the body cavity of the mosquito and accumulate considerably in its salivary glands, which also lie in the body cavity, so that when the now infective insect bites a healthy person the sporozoites are injected with its saliva into that person's blood, where they grow and multiply non-sexually, and after a definite interval usually reveal their presence in a paroxysm of malarial fever.

The mosquito thus is the medium for the necessary sexual reproduction of the malaria parasites; eventually the insect not only becomes a kind of supersporocyst at whose expense the actual sporocysts and their sporozoites are developed and nourished, but also acts as the locomotor instrument for distributing the sporozoites and planting them in their future sphere of action.

So far as is known, the only mosquitos that serve as nurses for the malaria parasites of man are mosquitos of the genus *Anopheles.* It can hardly be supposed that these parasites originated at the outset either in man or in *Anopheles* mosquitos. Kindred parasites inhabit the blood of other mammals as well as of birds and reptiles and are distributed by other kinds of blood-sucking insects, and it is reasonable to believe that all may have had a common origin and, up to a certain point, a common line of evolution, and that the species now adapted to man were derived, through the intermediation of *Anopheles* mosquitos, from forms whose evolution had been hammered out quite independently of the human race. Not every one of the many species of *Anopheles* is susceptible to infection, nor of the susceptible species are all equally so, or indifferently so under all conditions. Again, not all species of *Anopheles* are disposed to attack man, or to shelter in houses. Furthermore, although under favourable conditions the sexual development of the parasites in the mosquito is completed in about ten days, and although under ordinary circumstances the sporozoites would be discharged from the salivary glands of the infected insect in the course of a few bites, yet the sexual development may be much delayed by cold and other unfavourable conditions, and the salivary glands might remain infective for a long time if the insect remained inactive or torpid.

Ross's great work, which was experimentally elucidated with a common malaria parasite of birds, was the outcome of Manson's illuminative discovery of the necessary intermediation of mosquitos in propagating lymphatic filariasis, a disease, common in most tropical countries, caused by the invasion of the lymphatic system by the parasitic worm *Filaria bancrofti.* In certain phases of this disease the female worm gives issue to swarms of minute embryos, or microfilariae, which are carried into the patient's blood and are usually found in the superficial blood-vessels at night. Manson, in 1878, persuaded a Chinaman with microfilariae in his blood to suffer himself to be bitten by some common house mosquitos during sleep, and on examining the complete insects at intervals during a number of days following their infective repast he traced the ingested microfilariae through definite stages of larval development in the insects' stomach and muscles. Subsequent observers, of whom Dr. G. C. Low was the first to publish his investigations, discovered that the larval filariae find their way into the proboscis of the mosquito, whence on occasion offered they escape into the skin of a fresh human victim. More than a dozen species of mosquitos are now known to be capable of acting as intermediary host to the larvae of the worm of lymphatic filariasis.

Yellow fever is another disease which, so far as is known, is communicated from man to man exclusively by mosquitos of one species, namely, the notorious *Stegomyia fasciata.* The connexion between this characteristically house-haunting insect and the disease was inferred by Dr. Finlay of Havana in 1881, and was experimentally demonstrated by the U.S. Commission under Dr. Walter Reed in 1900. Here again, as in malaria and filariasis, the specific parasite of the disease must undergo a definite development within the insect, since the insect can become infected only if it feeds on a patient during the first three days of fever, and does not become infective until at least 12 days after so feeding.

Another disease spread in this way by mosquitoes is dengue fever. The actual virus of the disease has not yet been demonstrated, but there is good proof that it is transmitted from sick to healthy persons by two of the commonest house-haunting species of the tropics, namely *Stegomyia fasciata* and *Culex fatigans.*

Mosquitos may, possibly, spread other infections mechanically. Indeed they are known to be one of several kinds of flies that mechanically transport the eggs of the "macaw worm" (*Dermatobia hominis*) to its host. But such mechanical work is something different from the constant and indispensable biological accommodation which mosquitos alone provide for the parasites of filariasis, malarial fevers, and yellow fever, outside the human body.

Almost as notorious in recent history as the *Stegomyia* and *Anopheles* that at one time threatened to stop the construction of the Panama Canal are the tsetse flies, which, as intermediary hosts of the trypanosome parasites of sleeping-sickness, have depopulated certain parts of tropical Africa. These bloodthirsty insects, which constitute the genus *Glossina,* are akin to the stable-fly (*Stomoxys*), the house-fly, and the blow-fly, all being included in the great family of *Muscidae.* Except for one species, *Glossina tachinoides,* which ranges into the extreme south-western corner of Arabia, the entire genus *Glossina* is restricted to the torrid regions of the African continent. The trypanosome animalcules, which, so far as the species that cause disease in man and domestic animals in Africa are concerned, are associated mainly with tsetse flies, occur in the state of nature in the blood of all classes of vertebrate animals in most parts of the world; many, if not all, of the trypanosomes living naturally in the blood of wild animals appear to be harmless to their hosts, and it is perhaps because the trypanosomes that get into man and domestic animals, by the agency mainly of biting insects, are trypanosomes out of their proper place, that they are hurtful.

Recent investigations, beginning with the discovery made by Sir David Bruce in 1895 that the destructive "tsetse-fly disease" of domestic animals is due to a trypanosome parasite in the blood, have established the facts that there are two varieties of the human trypanosome disease known as sleeping-sickness, one predominant in equatorial Africa and transmitted mainly by *Glossina palpalis,* the other predominant in south-eastern tropical Africa and transmitted mainly by *Glossina morsitans;* that in both cases the respective trypanosome undergoes definite stages of development in the fly's gut and at last settles itself and continues to proliferate in the fly's salivary glands; and that a fly once infected remains infective by its saliva for the rest of its life. Thus in a general way the part taken by tsetse flies in spreading sleeping-sickness is similar to that taken by *Anopheles* in spreading malaria. But there is this difference: first, that the development of the trypanosome parasite in the tsetse fly is not actually known to have any sexual interpretation; and secondly, that although in epidemics of sleeping-sickness the fly derives its infection from human sufferers, yet in other circumstances it may possibly become infected from a wild animal, since trypanosomes morphologically indistinguishable from those that cause disease in man in Africa have been observed living naturally in some of the big game animals and also in the wild tsetse flies. The existence of these natural foci of possible—though not demonstrated—infection must enormously increase the difficulty of controlling sleeping-sickness. On the other hand, the laboratory experiments of Bruce and others have shown that only a small percentage of tsetse flies fed on infected blood take the infection. Finally it should be mentioned that there are some who still believe that in certain circumstances a tsetse fly may transfer infection from man to man mechanically on its proboscis.

In the instances reviewed so far a blood-sucking insect—mosquito or tsetse fly—acquires a specific infection while feeding, incubates it for a definite term during which infectivity is latent, and then at length transmits it, in the act of feeding, to another susceptible host. In this manner also *Conorhinus megistus* and other Reduviid bugs have been shown to transmit the trypanosome of Chagas's disease in South America, and in like manner the midge *Phlebotomus papatasii* is believed to transmit the virus of phlebotomus fever. In the same way, probably, as Manson suggested, the Tabanid flies *Chrysops dimidiata* and *silacea* in West Africa foster and transmit a filarial worm, *Filaria loa,* that is troublesome to man

in the working of this plan is shown by the fact that the system, which originally included medicine, surgery, and pediatrics, was in 1920 extended so as to take in gynaecology and obstetrics. The system was also adopted in the main clinical branches by the medical departments of Washington University (St. Louis), Yale University, Vanderbilt University, university of Chicago, and the university of Rochester.

*China.*—Through a subsidiary board (the China Medical Board) the Rockefeller Foundation of New York has established in China a modern medical school. The Rockefeller Foundation has furnished funds amounting to $8,000,000 to build and equip the Pekin Union Medical College, and in addition it was in 1921 supporting the institution on the basis of a budget for the year amounting to $500,000. The institution furnishes two years of pre-medical work, and intended to develop a four-year medical course. In addition to the undergraduate training of Chinese physicians, it will provide graduate training, offers short courses for physicians in the field, and endeavours to extend in the Orient a popular knowledge of medicine and public health. The China Medical Board also aids four other medical schools in China carried on by other organizations.

*Belgium.*—The university of Brussels had in 1921 planned a complete reorganization of its medical department. The city, the State, and the university coöperated in maturing plans for a modern teaching hospital, and new, well-equipped laboratories on a single site. Approximately 100,000,000 francs was needed to finance the enterprise, of which 40,000,000 was pledged by the Rockefeller Foundation. (A. Fx.)

*Canada.*—There were in Canada eight medical colleges in 1921 giving a complete course leading to the degree in medicine. In every case the college forms a part of a university, and most of them are to be found in the eastern provinces. In the West only one university (Manitoba) gives a complete medical course, though the university of Alberta offers the first three years of a six-year course, her students as a rule finishing their work in one of the eastern universities. During the years 1910–21 there was a steady advance in standards in the medical curriculum. The four-year course, which followed a minimum entrance requirement of Junior matriculation, was first increased to five years and later to six years in most of the schools. The five-year course was planned partly to meet the demand for increased instruction in the so-called pre-medical sciences and partly to give more time for the clinical branches. Where this course is in force the first year is devoted to biology, chemistry and physics, the second and third years to anatomy, physiology, histology and embryology, physiological chemistry, pharmacology, pathology and bacteriology, the fourth and fifth years practically to the clinical subjects, namely, medicine, surgery, obstetrics and gynaecology with their various special branches. The increase to six years gives more time to the clinical subjects, and in addition enables the Faculties of at least some of the schools to offer certain electives or options. This latter plan gives to the better-class student an opportunity to graduate with more than the minimum requirements for the degree of M.D. The six-year course is given in certain of the schools entirely within the medical department, although the curriculum includes certain courses to be taken in the other Faculties. Other schools plan to require two years as a pre-medical requirement to the four-year course. These two years may be taken in any of the standard universities and must include biology, chemistry and physics. At least one school was in 1921 planning to add to the four-year course a hospital year, which must be taken before graduation. In most of the medical schools the regular course in medicine leads to the degree of M.D. or to the degree of M.D.-C.M. One school gives the degree of M.B. at the close of the regular course, with the M.D. one year later on presentation of a satisfactory thesis. The combined degrees of B.A.-M.D. or B.Sc.-M.D. may be obtained in practically all the schools in seven or eight years. A special degree of B.Sc. (Med.) may be obtained in two of the schools by a year of special work at any time after the third year of the regular course in medicine. (J. W. S.)

**MEDICAL ENTOMOLOGY.**—What used to be called comprehensively "economic" entomology is now more conveniently divided into two distinct branches—economic (*see* ECONOMIC ENTOMOLOGY) and medical. In its medical bearings the scope of entomology comprehends not insects only but arthropoda of every kind directly hurtful to health. Until about 1880 the fact that many arthropoda can bite and sting, and that some are troublesome parasites of man, was not thought important enough in medical practice to require special attention in their entomological aspect; but when in the last quarter of the 19th century the startling announcement was made that one of the commonest diseases of the tropics is propagated by a bloodsucking insect it was soon realized that light might be thrown on many obscure problems in the causation of infective disease by a precise knowledge of the arthropoda that come into contact with man. This illuminating doctrine was first opened out in 1879, when Sir Patrick Manson, at that time a plain medical practitioner in China, published the essential parts of an experimental proof that the parasitic worm which causes the disfiguring febrile and subfebrile diseases known collectively as filariasis is communicated from man to man by a common house-haunting mosquito. It is true that long before 1879 seasonal fevers in several parts of the world had been ascribed, not only in popular tradition but also by plausible argument, to the bites of insects, but these vague glimmerings of the truth had not been regarded very seriously, and Manson was the first to demonstrate, by verifiable experiment, that in such cases the insect plays an indispensable triple part, namely, (1) after infecting itself with parasites responsible for the fever by imbibing the blood of a human being infected with them, (2) to provide in its own organs and tissues the appropriate medium for the growth and development of the parasites so absorbed and finally (3) to carry the parasites so fostered to fresh human victims. The precise manner in which the filariated mosquito passes on its acquired infection was not settled by Manson, but his wonderful discovery originated that new branch of study where a full and exact knowledge of all the arthropoda that touch man in his person, his dwellings, and his food and drink, finds, as Medical Entomology, a rational application in the control of disease.

*Subject-matter.*—In dealing with the subject-matter of Medical Entomology it is convenient rather than severely logical to group the arthropoda inimical to health in five categories, according to the nature, the direct effects and the after consequences of their results, namely as (1) simply parasitic, (2) simply predaceous, (3) specifically infective, (4) contaminative and (5) venomous, the third and fourth being far the most important.

*Simple Parasites.*—Here are included all those arthropod parasites that are hurtful solely by their presence on or in the body and not by any subsequently disclosed effects. Such are the itch-mites (*Sarcoptes*) specific to man, and the numerous food-mites, animal-mites, bird-mites, insect-mites, harvest-mites, etc., which in certain circumstances or at particular seasons may attack man, though not normally parasitic on him or in every case parasitic at all in normal habit. Though they usually attack the epidermis these mites may get into the bowel, or the lung, or the bladder. Such also are those muscoid flies which in their maggot stage are constantly and entirely dependent on warm-blooded animals for their existence: two such species of maggots are notorious subcutaneous parasites of man, namely the "macaw worm" (*Dermatobia hominis*) in tropical America, and the "tumbu" (*Cordylobia anthropophaga*) in tropical Africa. Bluebottles, flesh-flies and other domestic flies, which normally deposit their eggs or larval progeny in decomposing meat and carrion, may be attracted for this purpose to foul and neglected wounds, or to the eyes, nostrils and other natural orifices of unclean or incapable humanity, with dire results: the "screw-worm" flies (*Cochliomyia* in America and *Chrysomyia* in India) are said to be particularly prone to this deplorably mistaken instinct. Living maggots of many species of flies may find a congenial abode in the human bowel, as also may larvae of other orders of insects. Other simple parasites of man are the "Chigger" flea (*Dermatophilus penetrans*) common in certain parts of tropical America and Africa, the pregnant female of which embeds herself in the skin; and the "Congo floor-maggot" (*Auchmeromyia*) of tropical Africa, a maggot which infests native huts like a bedbug and sucks the blood of sleeping people, though the parent fly is harmless. An abnormal and misdirected parasite that, in places where large snakes are numerous, may get encysted in the human viscera, is the larva of the extraordinary wormlike arthropod *Porocephalus*, the adult of which is a bloodthirsty inhabitant of the lungs of snakes.

*Predaceous Arthropoda.*—To this category may be relegated a miscellany of blood-sucking insects, etc., the bite of which may be painful or may even cause severe inflammation, but is not known to be followed by any specific infection apart from a chance of ordinary septic contamination as a result of scratching. Though there are times and places when these insects may be an intolerable burden to travellers or to country folk, they have no preference for human blood and no particular affection for houses. They cannot therefore be regarded as a standing menace to the public health, although they may be treated with a reasonable amount of suspicion, because some of them are known to spread specific infections among domestic stock, and also because they may be chance mechanical carriers of some individual contamination, or may have parasites proper to themselves which might possibly under certain circumstances be transferred to man. This suspicious assemblage includes many species of mosquitos and gadflies, a lot of midges (*Simulium*, *Psychoda*, *Culicoides*, etc.), and numerous species of muscoid flies (*Stomoxys*, *Haematobia*, *Lyperosia*, etc.) that usually feed on cattle; also various flies (*Leptidae*, *Asilidae*, etc.) that normally feed on

As a general proposition it may be maintained that, although there are many occasions when systematic attack with destructive appliances is advisable, and several instances where it has been eminently successful—the Herculean cleansing of the yellow-fever and malaria stricken Panama Canal Zone from infective mosquitos by Gen. Gorgas and his staff being the crown and garland of them all—yet the only permanently successful procedure against a harmful arthropod is to upset its environment by steady perseverance in the ordinary principles of hygiene.

The truth of this proposition is illustrated by the history of malaria in England. Not so very long ago malarial fevers were quite common in many parts of that country: in 1657 John Evelyn's son Richard died at Deptford " after six fits of a quartan ague ": in Shakespeare's time ague must have been an every-day affair, for it is a familiar word in the mouth of his people, from homely persons like Mistress Quickly to great personages like Hotspur and Richard II.: Sir John Falstaff died of a " burning quotidian tertian," old John of Gaunt expired in an ague fit with " frozen admonitions " on his lips, and Sir Andrew Aguecheck is a catch-name for a shivering coward. Yet, except in a few water-logged spots where it may still linger, ague quietly disappeared from England ere ever any connexion with *Anopheles* mosquitos was dreamt of, or ever any malaria parasite had been discovered by a Laveran, although the species of *Anopheles* that used to spread it in England are still familiar British insects to those who know where to look for them. *Anopheles* mosquitos prefer to shelter in dark damp habitations, and they do not fly far from the waters where they are bred; and what seems to have happened in England is that, in the general improvement of drainage and sanitation, conditions have changed so completely that the population no longer lives among the breeding-haunts of *Anopheles* in houses that offer any attraction to those insects, and that thus the old communion between man and *Anopheles*, by which malaria was fostered, has gradually been dissolved. Something of the same sort has happened in the well-kept European quarters of some of the large towns of India.

It follows that medical entomology is really a branch of hygiene—a branch that finds its fullest application not so much in settled countries where man has long since set a bound to organic nature, as in those vast imperfectly developed tropical territories where sanitary arrangements are crude or non-existent and man is struggling with his organic environment.

As a branch of hygiene medical entomology should also be concerned with questions of the unwitting dissemination of pathogenic arthropoda in the intercourse of trade and travel, and in the special circumstances of war; and also with difficult problems relating to the destruction of such elements of the fauna of a particular territory as are believed to foster some local noxious arthropod, and to the introduction of such exotic species and parasites as are thought likely to destroy some local noxious arthropod, as sanitary measures; for such measures, if lightly undertaken, may start new mischiefs without mitigating those they are intended to check. (A. A.)

**MEDICINE AND SURGERY** (*see* 18.41 and 26.125).—By the year 1910 medical thought had reached one of its turning points, though this fact was not immediately evident. The great age of bacteriology had so vastly enriched our knowledge of disease that other aspects of work had been somewhat neglected. The belief prevailed that every disease was due to the presence of some microörganism, and that patient effort was bound, sooner or later, to find the specific microörganism in each case and enable a great work of prevention to be undertaken. In consequence bacteriology attracted the best brains in medicine, and enormous labour was expended in the search for organisms and in the study of their methods of growth. The fruits of this labour look smaller in the retrospect than the hopes concerning them which were entertained. A few new organisms have, it is true, been discovered, for example the spirochaete of infective jaundice (Weil's disease), the so-called filter-passers, and the still rather dubious rickettsia bodies supposed to be associated with typhus fever, trench fever and other conditions. Some differentiation, too, has been made between various "strains" of bacteria, notably in connexion with cerebro-spinal meningitis and bacillary dysentery (*see* BACTERIOLOGY). But an impression has gradually arisen and is growing that the greatest conquests in this field belong to the past. The trend of modern ideas is rather towards the application and elaboration of the knowledge newly obtained, and its absorption into the general body of medical thought.

### I. GENERAL PROGRESS IN MEDICINE, 1910–21

In any review of recent progress the above considerations must be borne steadily in mind. The mere circumstance that many common diseases—for example measles, scarlet fever, rheumatic fever—are still unrelated to a specific causative organism is much less significant than the fact that the after-effects of these complaints have been intensively studied and that the application of the laws of bacteriological invasion and growth has saved many victims who in other days would have perished.

One of the first results of the new orientation was a conception of disease as a process dependent on another parallel process—the course of an infection. The human body reacts in various ways to various assailants. This reaction is expressed in symptoms which tell us of the struggle going on, and may enable us, if we understand their mechanism, to arrive at conclusions about the nature of the attacking force and the strength of the defences. The researches of the laboratory are available here as an additional source of enlightenment, and so fall into their place in the general scheme of clinical medicine.

*Importance of Prognosis.*—When the World War broke out in 1914 this was the point which had been reached. Sir James Mackenzie and other thinkers, whose outlook was primarily clinical, were recalling attention to the lack of knowledge of symptoms and the lack of understanding of their importance. Medicine, they declared, was concerned too much with the gross signs of disease, too little with its earlier manifestations. The *post-mortem* room had too great an influence on opinion, and even the laboratory had failed to perceive that a vast body of truth lay beyond its reach. The positive side of this teaching was the setting-up of certain functional tests to replace the physical ones then in vogue. It was argued that, no matter what deviations from the normal form an organ or system might show, if it remained functionally efficient it could not, on account of such deviations, be condemned out of hand.

This doctrine was really a challenge. It demanded a restatement in the name of prognosis. The physician must be able to interpret symptoms and laboratory findings in terms of life. He must be in a position to tell his patient what a particular sign betokened, how it would affect him, and how its cause might be removed or rendered harmless. In short, the physician must draw upon all the sources of information available, yet must not abrogate his place as interpreter.

The position taken up was assailed from several quarters. But the outbreak of war served almost immediately to reveal its strength. When that event took place the medical profession was called on suddenly to examine a vast number of men and express views as to their fitness for field service. These views were stated with the knowledge that they would be put to the test immediately and that if they were erroneous the fact would soon be discovered. A test of this kind constitutes a great event in medicine. It will certainly be seen in the retrospect as one of the turning-points of the science. For it brought the whole body of knowledge to trial; it brought the exponents of every theory to account. More than this, it revealed the key to the problem of future progress—prognosis. The doctor was asked to say what the patient could do; it was not enough merely to recount symptoms or signs. Looked at in this way every medical board paper was a kind of forecast.

Almost at once the deficiencies in knowledge began to be apparent. It was found by experience that the organic view was not equal to the strain imposed on it. Those who had been content to recognize a sign and give a name to it perceived that this was not nearly enough. It was not enough even to find a particular germ in a laboratory, nor to discover by the use of X rays some abnormal condition. The laboratory, with all its

intricate and beautiful machines, was unable to answer the great new question: "What effect will this symptom or sign exercise on the field of battle?"

The whole weakness of the purely laboratory point of view was exposed in a flash. As a means of diagnosis this branch of medicine was of enormous value; as a means of arriving at a prognosis its value was much less. The new task of medicine was to interpret the findings of the laboratory and of the senses in terms of active life.

At the beginning there were many failures, and an outcry against the medical boards arose. Instances were cited of men who had broken down badly, though they had been passed "fit," and these made a considerable effect on the public mind. Nor did the retort that medicine had failed to find any sign of disease avail much. The layman replied that it was the doctor's duty to make a reasonable prognosis.

*Clinical Medicine.*—This difficulty led with great rapidity to a new orientation. Clinical medicine—the study of abnormal functioning *at the bedside* of the patient—became really important again; and the clinical revival which began at that time spread with amazing rapidity. Within a few years workers in every school of thought were adopting what are spoken of as "functional" standards.[1]

*Heart Disease.*—In no direction was progress so rapid as in the study of heart disease. This disease had escaped to some extent the bacteriological obsession. It remained a clinical problem because no definite infective agent had been found. In consequence old ideas prevailed and the shadow of the *post-mortem* room lay over every sign and symptom.

Popular apprehension of heart disease caused physicians, moreover, to stickle at sending any patient with a "murmur" to the fighting line. Happily, the British army medical authorities took a firm line, called to their help the leaders of what was then spoken of as the New Cardiology, who boldly applied their functional tests, and on the strength of them formed conclusions as to fitness for service. In spite of some anxious protests the views expressed were carried into effect, and men sent to fight who, in peace time, might possibly have been sent to bed. The result fully justified the method. Heart diseases, instead of proving the bugbear they had been in the early days of the war, ceased to give much trouble. This news spread rapidly, and a new era in the medical study of the heart began. Incidentally it was found that exercise greatly helped many sufferers from so-called heart affections, and later still many of those affections were traced back to bacterial diseases. Thus the so-called toxic theory of heart disease was strengthened. It came to be understood that with the advent of an infection disturbances take place in the mechanism of the heart and result in a depreciation of functional efficiency. This can be restored by two methods:—destruction of the invading germ (*e.g.* in syphilis) or increase in the human resisting power (*e.g.* exercise).

Thus modern medicine achieved its two great principles—the understanding of the meaning of signs and symptoms in terms of active life, and the necessity of conserving and building up natural resistance against the enemies of the body. These principles, it will be seen, are complementary to one another. For prognosis must always vary with treatment. In the days before antidiphtheria serum was discovered the prognosis in diphtheria was very bad. Since the use of serum has become general it is, on the whole, good.

*General Immunity.*—The early days of the bacteriological period had seen a movement away from drugs whose uses are directed to restoring the patient's strength. Instead, great search was made for substances capable of killing bacteria in the human body, and antiseptics and specifics of many kinds were introduced— *e.g.* salvarsan, new combinations of quinine, *sera*. Later still the extension of methods of vaccination, for increasing specific natural immunity, occupied the forefront of research. Now general immunity, health in the broad sense, commanded attention. There was a revival of physical culture, and this was applied to the diseased as well as to the healthy.

Inevitably such a movement brought the study of physiology into new prominence—and this indeed is another of the landmarks in a very interesting period. One of the applications was the work of Sir Almroth Wright and his assistants in war wounds. When the war began, surgery had passed back again from antisepticism to asepticism. It had been found that the technique introduced and used by Lister was not necessary, that antiseptics were troublesome, and that absolute cleanliness secured all the advantages which these bacterial—and protoplasmic—poisons had gained for us.

*Treatment of Wounds.*—The treatment of wounds made by a surgeon in a modern hospital and the treatment of wounds made by shells on the battlefields of France were two very different things. Asepsis was no use when sepsis was already present. As a consequence the cry "Back to Lister" was raised, and the wounds of war were deluged with strong solutions of carbolic acid, iodine and other substances. This procedure naturally resulted in some trouble, and at length Almroth Wright was commissioned to make an investigation of the whole subject.

His conclusions were that antiseptics are largely useless because they fail to kill the germs of septic poisoning but do injure and weaken the tissues in which these germs are embedded. They thus interfere with a physiological process of repair and cleansing. Wright conducted some most delicate experiments, the object of which was to determine how wounds tend to heal and how deleterious matter is got rid of. He studied the lymph, or natural fluid, which flows out when a wound is made, and came to the conclusion that this, so long as it is fresh and uncontaminated, is an agent capable of destroying bacteria. If, however, the flow of lymph is dammed up, the fluid becomes corrupted and then forms an excellent pabulum for bacteria.

The case against antiseptics was that they tended to cause coagulation of the lymph and so produced "crusts" which dammed up the lymph flow. Thus more harm than good resulted. Wright, on the contrary, used salt solutions of various strengths, which increase lymph flow, and was able by this means to make wounds cleanse themselves. His views were received with immense interest, and were soon under discussion in every theatre of war and indeed in every civilized country. By some they were hotly contested, but they served effectually to put an end to the rash and indiscriminate use of antiseptics. Meanwhile, however,

[1] There was founded in 1920 by Sir James Mackenzie in the town of St. Andrews, Scotland, an Institute for Clinical Research which had hitherto no counterpart in the world. The reasons for taking this step were twofold:—(1) While the signs of organic disease are well known and more or less easily recognizable, those of disease before organ damage occurs are almost entirely unknown. Disease before organic breakdown is thus an uncharted country. (2) In order to chart it, it is necessary to study carefully and extensively the so-called "trivial" symptoms. Only by such an investigation can light be obtained on the real meaning of those symptoms. The town of St. Andrews was chosen for the site of the work because it is small and self-contained. It was felt that, if the history of any given symptom was to be followed up, and its progress into the future—the only final proof of its seriousness or triviality—to be determined, a resident and non-shifting population must be studied. Moreover, the work must be carried out by general practitioners because they alone are consulted by sufferers from trivial ailments, and so alone see the earliest manifestations of disease.

Sir James Mackenzie gathered around him the local medical men at St. Andrews, and they all became research workers in the institute. The methods employed are those of the bedside amplified and extended. Every symptom of which a patient complains is carefully observed and noted down and the records are filed, indexed and classified. Any laboratory examination which may be necessary can be carried out in the institution, but for the most part such instruments as the X rays are inapplicable, there being no objective signs of disease. Periodically a particular symptom is studied intensively, for example exhaustion. By 1921, several important papers had come from the research workers. Their work revealed the fact that all symptoms depend for their production on disturbances of the normal reflexes of the body, another way of saying that they are exaggerations of physiological events. As most reflexes depend on the presence of a stimulating agent, a nervous mechanism and an organ or region stimulated, it is evident that a new pathway to the study of disease had been suggested. Thus, a morbid condition may fall under the heading of one or other of the three factors mentioned: it may be an excessive or extraordinary stimulus (a stone in the ureter), or an agent acting in the nervous mechanism (the toxin of a disease) or actual involvement of organic structure.

another worker, the Franco-American surgeon Alexis Carrel, had introduced with Prof. H. D. Dakin an antiseptic not formerly much employed. This was a hypochlorite solution which had been christened "ensol" or "Dakin's solution." The technique employed was more important than the antiseptic, and to some extent justified the views of Wright. It was a continuous drainage secured by the use of cans and rubber tubes. The wound was thus kept flushed and all its discharges were washed away. This system found many supporters but was attacked by Wright. Finally a third school dealt with the problem and brought to its solution the methods of the great German biochemist Paul Ehrlich. Ehrlich's idea was that a drug possessing a specific effect on specific forms of protoplasm might be found in connexion with any bacterium. He proved his case with his own discovery "salvarsan" or "606," which possesses a special destructive power where the spirochaetes of syphilis are concerned.

In the case of the bacterial poisons of wounds another substance, flavine, was brought forward. This preparation belonged to the same group as salvarsan; it was used in the first instance by Prof. C. H. Browning. Very good reports of its efficacy were received. But again Wright and his followers attacked it on the ground that it failed of its object, the destruction of bacteria, and interfered with the physiological processes of nature.

It cannot be said that any permanent settlement of this dispute has as yet been reached, but it does seem clear that the foundations of Wright's work—physiological study—will be hard to shake. Indeed he has here an advantage over all his critics, the nature of which they did not seem at first to realize.

*Vaccine Methods.*—To Wright indeed belongs the credit of having brought the laboratory to the bedside. He saw that no method can succeed unless it is based on practice. Practice in this sense means physiological principle. It was recognition of this fact which inspired his antiseptic studies. Further, though this has not been sufficiently appreciated, it was recognition of it which enabled him and those who worked with him to bring the anti-typhoid vaccination to the high pitch of perfection it had reached when war broke out.

*Typhoid.*—Of the single facts of medical history during the war period the success of this anti-typhoid vaccination is certainly the most conspicuous. Such a success was indeed undreamed of, for of all the enemies of the soldier typhoid fever ranked first. A study of earlier campaigns reveals the fact that this scourge usually swept away large proportions of the armies engaged in European warfare, and in some cases the casualties by bacilli—chiefly typhoid—stood to the casualties by bullets in the proportion of 80 to 20. Thanks largely to the preventive inoculation against typhoid this condition of affairs was reversed in the World War, the proportion being gun-shot wounds (including all forms made by all manner of missiles) 80 and disease 20. The credit for this result is due largely to Sir Almroth Wright and Sir Wm. Leishman, who devoted endless trouble to the work of perfecting this brilliant application of bacteriological and physiological principles to preventive medicine.

*Tetanus.*—Not less striking, though less dramatic, was the success achieved in the prevention of tetanus or lockjaw. This dreaded disease began to manifest itself almost at the beginning of the campaign. Before the battle of the Marne was fought it was relatively prevalent and was causing great consternation, for it was recognized that the intensively cultivated soil of Europe was impregnated with tetanus bacilli, and that thus every wound was dangerous. Moreover, up till this time the treatment of tetanus had proved singularly ineffective, so much so indeed that the patient was regarded as doomed.

As the tetanus bacillus presents many features in common with the diphtheria bacillus, and as the antidiphtheria serum had proved a very great success, it was thought that a serum prepared in the same manner might solve the tetanus problem. This hope had not been realized in practice at the time of the outbreak of war. Nevertheless, there was some reason to think that, though the serum failed when given after the disease had declared itself, it might not fail if administered at the time of actual wounding.

Tetanus, as is well known, takes several days to incubate. In consequence, there is available a period in which measures for its suppression can be carried out. This fact was the basis of the antitetanus inoculation which was begun experimentally in 1914. From the outset the experiment succeeded beyond the expectation of those who had planned it. Tetanus became a rare disease, thanks to the fact that every wound, no matter how trivial, was regarded as a possible source of danger. It was an order that as soon as a soldier got even a scratch of the skin he must report to his medical officer. A prophylactic dose of serum was then administered.

At a late period the War Office set up a Tetanus Committee under the chairmanship of Sir David Bruce. This committee investigated cases of so-called "delayed" tetanus, and also those cases in which tetanus made its appearance at long periods after the initial wounding when surgical measures had been carried out on the wound. The view which was formed was that the bacilli in such cases were walled in and rendered innocuous; but manipulations of the wound were apt to break down the walls and so release the toxins.

*Shell Shock.*—Meanwhile the circumstances of war were directing attention to a series of new disease conditions which the peace-time physician had not encountered in so severe a form. Chief perhaps among these was the nervous disturbance caused by high explosive shells. At first a number of wild statements were made and believed, but presently, and thanks in no small measure to the common sense of Sir Frederick Mott and other distinguished neurologists, some light on the darkness was obtained. Mott pointed out that among the large group of cases classed as shell-shock patients there were a number who had suffered actual physical injury of the brain as a result of explosives. If these people died, punctiform haemorrhages were found in the brain substance.

These cases were not psychopathic, they were organic lesions—cases of injury. After elimination of this group there remained a large group of individuals, considerable numbers of whom had not received any injury. These cases were often very severe, but they differed in no material respect from the neurasthenics and victims of functional neuroses well known in civil life. The question was asked why these patients should break down whereas other men could be severely wounded and yet show no sign of nervous disturbance.

Various answers were given to this question, and probably all of them contained a germ of truth. Thus it was pointed out that hereditary influences played a part in some of the cases. The men came from mentally unstable families; they themselves had only just managed to support the conditions of ordinary life. The conditions of life in the trenches broke them down. Again, many of these patients were clearly the victims of chronic infections such as rheumatism, which exercise an irritant effect on the nervous system. Thus the men were more easily stimulated than in normal cases, and so more easily fell victim to the excessive stimulation of war.

Thus new recognition was given to relationship existing between disease and temperament, between the nervous system and the functional activity of the body. It was seen with a clearness not before achieved that the mental case may be the case of disease, slight, unrecognized, yet perpetually active. The treatment of these cases occupied a large number of distinguished workers. Little by little a process was evolved whereby disease elements were eliminated so far as possible before mental conditions as such were pronounced upon. Thus the patient's general health was made the subject of careful study, while at the same time his mind was being dealt with.

*Psycho-analysis.*—The purely mental aspect of the subject forms one of the fascinating chapters of modern medicine. Never before was so vast a material presented to scientific workers. This material, too, came at an hour when a great upheaval in mental medicine was in process. The writings of Sigmund Freud of Vienna had just begun to find adherents among British psychiatrists. They were the subject of hot dispute; but the first wave of incredulity was spending its force. Thus Freud's methods

were applied to many cases of shell shock and their value put to immediate test.

These psychic methods were founded on recognition of a mental field operating below consciousness and charged with various "repressions." A repression is a desire which for one reason or another cannot be fulfilled and so is forgotten. It does not again enter consciousness; but it nevertheless remains active and unsatisfied, and under various disguises attaches itself to desires which are permitted to become conscious and greatly intensifies those. Thus the patient shows abnormal reactions to certain stimuli and evinces abnormal likes and hatreds which cannot be explained in terms of his evident circumstances. This man has an unbalanced mental outlook, and, given circumstances such as warfare, will evince symptoms of nervous breakdown. The method of treatment suggested by Freud was to analyze his mental state, discover the repressed wish, and bring it into consciousness. Once the patient knows it and realizes it, it is said to lose its power over him.

The method is called *psycho-analysis*, and in some hands has yielded important results. It is now being widely practised. Unhappily, while in some directions perversely applied by Freud himself, it lends itself also to the uses of unqualified persons and also of mere charlatans. On this account it has to some extent fallen into evil repute. That it is, when properly applied, a great contribution to the study of the mind is nevertheless evident. Its application to shell shock did much to convince the medical profession of the necessity of seeing its work as a whole and not in little bits. It also helped to convince physicians of the importance of the "imponderabilia" in every case.

*Mental Hygiene.*—It had another effect not less far-reaching. There sprang into being a body of physicians who declared that mental effects of warfare could be prevented to a great extent if a kind of mental hygiene was instituted for the soldier. So far as possible the causes operating to lower his physical and mental vitality must be found and removed. Well-being must become a study. Effects of this theory were the rest camps, the convalescent depots, the insistence on games, on baths, on lectures, on medical supervision. Other effects included the care taken to show the soldier that if he fell ill or if he was wounded every sort of effort would be made for his safety and comfort. Thus while the enemy on the one hand was doing all in his power to break the soldier's *moral*, physicians of the new school were steadily and tirelessly building it up. In a large view of this work we are entitled to include every one of the schemes which had as their object the comfort of the soldiers—we are entitled also to include such appliances as steel helmets and gas masks. These were more than defensive armaments; they were expressions of preventive medicine as applied to the human mind in time of great stress.

That the success which attended these labours has left an indelible impression on modern medicine goes without saying. Circumstances and environment are now receiving a measure of attention never before accorded to them. The demand for playing-fields for the nation's youth, for swimming-baths, for holiday camps, is a part of this campaign. So is the interest which all doctors are exhibiting in food values, in housing, in ventilation, in industrial welfare. Indeed, the science of industrial welfare is largely a war product.

*Welfare Work.*—This science has made an immense progress in the last few years. Employers of labour have been aroused to the fact that their human machinery is as important, is indeed more important, than their working plant. In consequence, physicians have been called in to act as expert advisers to many great industrial undertakings. Attempts are being made to select suitable candidates for the vacancies in industrial life, and it is becoming a working maxim that to employ unfit persons is both unjust and uneconomic. The study of what is called "welfare" is progressing, and money is being laid out on good ventilation, on rest-rooms, on workers' canteens, on bathing facilities and other amenities. All this expenditure is found to return a profit both to employer and employed.

Moreover, the study of industrial fatigue has shown that it is in the highest degree wasteful to keep men at work after they have become exhausted. Thus, shorter hours of labour have been instituted on medical advice and have increased instead of lowered output. The method known as motion study has helped to eliminate wasteful movement in particular operations and so has added to the profit of them while reducing their cost. Further investigations have been carried out into the circumstances of what are known as "lost workers," *i.e.* persons who learn a trade only to leave it, and into those of industrial misfits.

The effects, too, of environment on industry have been studied from a new angle. The whole science of ventilation has been reviewed and restated. Thanks to the work of Dr. Leonard Hill, it is now accepted that ventilation is no mere question of cubic feet of air but is a large and difficult problem involving a study of air movement, humidity and temperature. Stimulation of the skin by moving currents of air is of as great or greater importance as the amount of oxygen available. Moreover, the drying quality of the air depends on its movements, and so the degree of evaporation of sweat on which cooling of the body largely depends. In this work Dr. Hill has employed an instrument of his own, known as the kata-thermometer, a thermometer the bulb of which is enclosed in a glove finger and kept moist. It records rate of temperature-loss in any given room. It is significant that changes in ventilation effected on the advice of Dr. Hill have resulted in a marked increase of output.

Another vastly important series of observations of this kind are those of Dr. John Scott Haldane of Oxford on dust phthisis. He has conclusively demonstrated that silica dust is the real agent of destruction. Coal dust is actually beneficial. Why this should be so is not known, but it would seem that the coal dust excites responses in the body which result in a cleansing of the lungs; silica or rock dust, on the other hand, excites no such response, and the gritty particles in consequence tear the lung tissue and prepare a nidus for the tubercle bacillus. An outcome of the work is the clever method of sprinkling coal dust in rock-dust mines. By this means the rock dust is rendered harmless.

The mining industry has further benefited by the work of Dr. Thomas Lister Llewelyn, who has traced miners' nystagmus or blindness to its cause—bad lighting. He has placed this subject on a sure foundation and made it possible to say that if certain changes in lighting are introduced this most costly and disabling disease will be abolished. (*See* INDUSTRIAL MEDICINE.)

*Orthopaedic Surgery.*—The immense strides recorded in this branch of medicine are paralleled by the brilliant advances in another. (*See* ORTHOPAEDIC SURGERY.) If the war influenced industrial medicine only indirectly, it actually revolutionized orthopaedic surgery. This study had rather languished in England owing to the relatively small number of cripples. In America, where infantile paralysis is rife, it had advanced farther. English practice, however, was well represented at the Liverpool school, at the head of which was Sir Robert Jones. The War Office called on Sir Robert Jones, and he became the organizer of a rest salvage corps, the duty of which was to mend the broken soldier. The subject soon divided itself up into branches; there was the work for the limbless at Roehampton, from which has come the modern light artificial leg. This appliance almost, if not completely, restores lost function; it is a permanent boon to humanity. Again, there was the astounding development of so-called "plastic" surgery, the result of which has been to render any disfigurement capable of great improvement if not of complete cure. The treatment of severe fractures, too, and especially fractures of the thigh was studied as a new problem and undertaken on new lines. These results are now a permanent gain to surgery.

General orthopaedics evolved from a method to a science. The study of muscle groups and their antagonistic action led to the formulation of new ideas and so to the application of new lines of treatment. Every case was considered on its merits and regarded as a separate problem; yet it was found that the same general laws could be applied to all. We are perhaps entitled to include in this progress the surgery of the heart, which was undertaken on a large scale in the war. As a result a remarkable diminution in death-rate from heart wounds was achieved both

in England and France. Further, the advances made in the treatment of surgical tuberculosis are really of an orthopaedic nature. They do not belong to war surgery, but they owe something to the conservative spirit which war surgery inspired. They consist, briefly, in preserving the integrity of the skin in all cases of tuberculous invasion of bones or joints. It has been found that if this is maintained the patient outgrows his disease—provided that he has good food and healthy surroundings. If, on the other hand, operative measures are carried out and so the skin broken, other bacilli and cocci enter the tissues, which, being weakened, form a suitable medium for growth. The severe septic cases are those which have been surgically treated. These new methods owe their origin to Sir Harry Gauvain, working at the Sir William Treloar's Cripple Home at Alton.

*Trench Fever.*—In the realm of medicine proper the war exerted an influence which must endure. Incidentally several diseases were encountered the existence of which had passed unrecognized before. One of these was trench fever, a condition closely resembling the muscular rheumatism of peace time, but characterized by bouts of fever, severe pain in the shins and great chronicity. This disease was investigated by a committee presided over by Sir David Bruce. Col. Wm. Bryan conducted the investigations. Thanks to the fact that volunteers offered themselves for research purposes it was proved that the disease is carried by lice, and that the infective agent is found in the excreta of these insects. The louse does not become infective until some 8–12 days after it has bitten a trench-fever patient. Thereafter it appears to remain infective indefinitely. Its excreta if scratched into the skin produce the disease after a period of incubation lasting about eight days. The disease spread with great rapidity owing to the conditions of trench warfare. It is calculated that some 500,000 persons were affected. Every effort was made to discover a cure, but in spite of this no success was achieved. The disease seems to run a chronic course and relapses are frequent. It is attended by nervous symptoms and also by some cardiac disturbances. As a consequence many people are now labelled " heart disease " and " neurasthenia " who are in reality sufferers from chronic trench fever.

Another disease of this kind came to be known as trench nephritis. It is a true acute nephritis of short duration but showing a tendency to relapse. The evidence, so far as it is available, points to an infection carried by lice. So far no specific organism has been discovered for either condition, but there is some reason to think that the rickettsia bodies which Arkwright found in infected lice are the causative agent. This view is supported by the entomologist Arthur William Bacot, who contracted the disease himself in Poland and found rickettsia bodies in the lice which had been on his person. These diseases accounted between them for a large proportion of the total war morbidity. Had not the work of disinfestation been very well carried on they must have proved a serious menace.

*Wound Shock.*—Another condition which received careful and intensive study during the war years was surgical or wound shock. A number of eminent physiologists and pharmacologists took part in this work, the names of Prof. Wm. Maddock Bayliss and Dr. H. H. Dale being noteworthy. Wound shock, it was found, is a complicated condition depending on a dilatation and permeability of the capillary circulation. A stasis or stagnation of blood results, mainly in the abdominal area (*see* INTESTINAL STASIS). The blood fluids tend to pass out of the circulation.

Bayliss suggested that this condition might be treated by injections of a viscid fluid which would increase the volume of fluid in circulation and at the same time be retained in the permeable vessels. His choice fell on solutions of gum arabic, which he accordingly introduced. The idea proved eminently successful, and it was found possible by the use of the gum arabic to restore patients who must otherwise have died.

A most interesting feature of this work was the discovery by Dale of a substance, histamine, having the power, when injected, of producing an artificial state of shock with fall of blood-pressure and symptoms of collapse. Dale's work was carried on side by side with that of Bayliss, and thanks to the combined effort a new physiological conception of the capillary circulation was arrived at. The subject nevertheless remains to some extent obscure and still engages the attention of many workers.

*Anoxaemia.*—Two other advances in medicine remain to be mentioned—the treatment of gas-poisoning and the testing of flying men. To some extent these matters overlap one another because they both gave impetus to a new study of respiration. From the work on poison-gas came Haldane's method of intensive oxygen administration in pneumonia and other conditions. From the necessities of the air was evolved the theory of " oxygen want." The term " anoxaemia " has now been added to medical nomenclature. It signifies not so much impurity of the blood as lack of purity—a negative rather than a positive quality. The chief sign of anoxaemia is cyanosis. The condition is of a most serious character. Arising out of this work came the idea of Haldane and his co-workers that the living membrane of the lungs is able to seize hold of oxygen and actively take possession of it. This quality of oxygen-reception is, it was suggested, capable of cultivation, so that a man might, as it were, develop it in himself to a high degree. More recent work, that of Bancroft, has, however, cast some doubt on the idea.

The medicine of the air (*see* AEROTHERAPEUTICS) is still in its infancy, but already it is clear that candidates for pilots' certificates must possess what is known as a rapid reaction time if they are to prove successful airmen. In other words, action must follow stimulus to action with great speed. This consideration has opened up new vistas in the physiology of nervous response.

(R. M. Wi.)

## II. Medical War Organization

When the World War broke out the British Army Medical Corps was a small body with a personnel amounting to about 1,000 medical officers. At the end of the war its personnel numbered over 12,000 medical officers, a vast number of orderlies and stretcher-bearers, nurses and laboratory attendants, constituting collectively the most efficient medical service ever created.

The deficiencies of the existing corps were seen within a week of the beginning of hostilities. Indeed, the extreme heroism displayed by the officers and men during the retreat from Mons only served to accentuate their ill-equipped condition. There was not a single motor ambulance; there were no hospital trains in the modern sense; the supply of surgical requisites was deficient. It is true that the frequent changes of base, from Boulogne to Havre and again to St. Nazaire and then back again to Boulogne, made it difficult to obtain supplies. Yet the condition of affairs aroused a great deal of anxiety, and those who saw the earliest ambulance trains—mere collections of wagons—set to work to improve matters.

In the late autumn of 1914 Sir Alfred Keogh, an ex-director-general of the Army Medical Service, was recalled to the head of the service and began the work of reorganization which was to prove so successful. At that time the first battle of Ypres was in progress, and the stream of wounded men which flowed down to Boulogne was overwhelming. It was a case for emergency measures. A large number of officers was hurried to the scene and within about 10 days order was brought out of chaos. The Casino and a large number of hotels were taken over, fitted with beds, equipped and filled. A few motor ambulances were got to work, and as many men as possible transferred to England by the hospital ships which, happily, were available. In this way the beds at Boulogne were kept for the very severe cases which could not at once bear a sea voyage.

This arrangement, formed out of the necessities of the case, became the basework of the whole organization. All through the war the medical service had three main areas of work—the front, the base and home. The idea was always to use the base for two purposes: the treatment of cases too ill to be taken across the English Channel immediately, and the treatment of cases which might be expected to recover within a short space of time. Thus evacuation to England was used for the most part in cases where immediate recovery was improbable, yet where the nature of the injury or disease was not such as to preclude a voyage.

This basework remained, but was subject to some important modifications as the campaign progressed. One of these was the tendency to move the operating surgeon nearer and nearer to the front. It was a recognition of the fact that in war-wounds every hour of delay prejudices the chances of recovery. A few experiments carried out at first tentatively showed, for example, that the mortality from abdominal wounds was greatly reduced when these were operated on within a few hours instead of within a few days. The success of these experiments led to the development of the field hospitals, situated close behind the lines. Thus, after a wounded man had been brought from the first-aid post to the casualty clearing-station, he was "sorted out" by a medical officer, and, if he seemed to require immediate attendance by an experienced surgeon, was sent direct to the field hospital, which might adjoin the clearing-station. Cases not so urgently requiring operation went by ambulance to the railhead and from there, by train, to the base.

Another modification was found in the introduction of convalescent camps. Experience showed that if a man was to make a good recovery he must be followed through all the stages of his convalescence. If he was allowed the freedom of the base town he often did himself hurt and always found it a great strain to get ready again for the life of the trenches. If, on the contrary, he was "kept in the machine," taken from hospital to what was a great military camp equipped with every conceivable means of healthful amusement, he recovered much more rapidly and never fell out of the army spirit.

These convalescent camps were therefore established in the near neighbourhood of the base hospitals. They combined sport and pastime with a certain measure of physical culture. Discipline was fully maintained. On coming to the camp a convalescent man found himself in the company of hundreds of other men all in process of recovering and all making ready for the fighting ahead. He lived in the war atmosphere. He trained for war. At the same time he was able to enjoy many different kinds of entertainments and to play any games he chose. He might also engage in gardening or less strenuous pursuits while strength was returning. At all periods of his stay he was under careful medical scrutiny. The camps relieved the burden on the hospital ships and also on the base hospitals themselves. They prevented an undue loss of fighting material, and, moreover, gave to the active forces the sense of being well cared for in the event of wounding, which is an important moral support.

Yet a third modification was the introduction of special methods of treatment in the field. An illustration is furnished by the camps for cases of soldiers' heart or nervous heart. This condition was investigated at the request of the War Office by a group of specialists in England who declared that it was not heart disease and that it could be benefited by a course of graduated exercise. Instructors were therefore obtained and trained in the application of the special exercises and were then sent out to France to work under the direction of highly qualified medical officers. Heart cases of all kinds were forwarded at once from the hospitals to the heart centres. Here they were sorted out into serious and non-serious types. The first class were sent to England forthwith to be discharged from the service as permanently unfit; the second class began at once the course of treatment training. By this means an immense relief was afforded to hospital accommodation—there were vast numbers of these cases—and a large number of useful soldiers were retained in the active force.

In the meanwhile Sir Alfred Keogh inaugurated, in conjunction with the Medical Research Committee, his famous system of team-work research on war diseases. He called to his assistance all the best British brains in medicine and he made it easy for any physician or surgeon with an idea to approach him. Very early in the day anti-typhoid vaccination was enforced throughout the whole army and every recruit received his dose of the vaccine as a matter of routine. Then came the Gallipoli campaign and with it the discovery that, while the vaccination protected against the typhoid bacillus, it did not protect against its prototypes, the paratyphoid bacilli A and B. This discovery was made the basis of an immediate inquiry, and the result was the introduction of a new vaccine giving protection against all the typhoid group of organisms. After this the typhoid fevers steadily declined and became a minor problem.

Another routine which was instituted was the administration to every wounded man, no matter how slight his wound might be, of a dose of anti-tetanic serum. This measure soon made tetanus a negligible factor. Methods of dealing with the infections of wounds also engaged attention and resulted in much greater care being bestowed on the cleansing and treatment of wounds near the front line. Teams of workers were also set to solve the problems of cerebro-spinal meningitis, which broke out severely in various camps, trench fever, trench nephritis, wound shock, gas gangrene, the treatment of fractures and so on.

In almost every instance valuable knowledge was acquired. So perfect had the organization become that it was possible to apply this knowledge forthwith. Thus a better spacing of sleeping accommodation reduced the incidence of cerebro-spinal fever, while the preparation of a serum having powers against all the four strains of meningo-cocci present reduced the mortality by some 30 per cent. As soon as it became known how great a part lice were playing in the spread of trench fever a campaign of disinfestation was started. The services of distinguished entomologists were secured, and these were commissioned and sent out to France to examine and report. The result was an added care of the bathing facilities for men behind the lines and a very perfect system of disinfestation of clothing by heat. In this way enormous numbers of lice and nits were disposed of and the incidence of the disease restricted. Sleeping-quarters were also taken under expert care, and blankets and night attire subjected to careful and continuous scrutiny.

The entomologist indeed became a part of army organization and had plenary powers which were undreamed-of in earlier campaigns. Acting in conjunction with the sanitary corps, he stood between the soldier and the deadly pest which threatened him. Large fly-destruction campaigns were inaugurated and every measure calculated to prevent the breeding of flies in or around camps was put into force. The results were exceedingly good, more especially in the East, where flies constituted a serious menace. In the same way, in the Struma valley, pools containing the larvae of mosquitos were drained or treated with paraffin and the troops thus protected against malaria. In Egypt, too, Col. Leiper was set to solve the riddle of that troublesome disease bilharziosis, and was so successful in his quest that within three months he had located the intermediate host of the parasite, a water snail, and suggested means for its destruction.

Indeed, the organization of preventive medicine in the war was as good in every way as the organization of curative measures. The sanitary corps developed to a state of efficiency which has probably never been equalled. Methods of chlorination of water were brought to high perfection, so that if the men obeyed the instructions issued to them—and most of them did—all danger from imbibing contaminations was eliminated. Cholera threatened, but it never became serious; even dysentery, though it claimed enormous numbers of victims at Gallipoli and elsewhere, was brought under a great measure of control. Nor was food inspection less successful. The army ate well throughout the whole war; it ate safely, thanks to the unremitting vigilance of this most capable body of officers and men.

An organization of this kind was ever ready to seize on and apply new methods. Thus the use of steel helmets was early suggested by surgeons in France and was finally enforced by the demands of the R.A.M.C. These helmets represent a very good example of preventive surgery, since head wounds, before they were introduced, had claimed great numbers of victims. The reduction in the number of those wounds after the helmets were obtained was a complete justification of everything urged in their favour. The small cuts and scratches, the scalp wounds, the bruises, which before had killed many useful soldiers, became things of the past.

Nor was the work accomplished in connexion with poison-gas less triumphantly successful. It is difficult to realize the immense

confusion occasioned in the ranks of the medical corps by the introduction of this method of warfare. The problem presented was new and terrible. Men who had been exposed to the fumes were brought in hundreds to physicians who had small idea of how to help them. Yet within a space of some three days measures had been devised. The medical authorities in England had obtained respirators and sent them out. The doctors in the field had learned to use them. Moreover, a body of expert chemists and physiologists were at once set to work to devise better protection and also to seek for efficient means of treatment. The extraordinary elasticity of the organization is shown by the way in which, within a very few weeks, anti-gas measures had been perfected and the treatment of gassed patients reduced to a routine. In this connexion the work of J. S. Haldane, of Oxford, must be mentioned. He introduced his intensive method of administration of oxygen, thanks to which the sufferings of gassed patients were greatly alleviated.

The organization was concerned at first wholly with the task of getting men back to the front. In course of time, however, it was seen that this policy would require to be extended in order to deal with the broken soldier. The reason was that the army had absorbed so many doctors and surgeons that outside of it means were lacking of giving adequate assistance.

The War Office was at first reluctant to add to its labours the care of many hundreds of thousands of disabled and sick men, but in the end consented. Thereafter the rule was that no man should be discharged from the service so long as it was possible to do anything further to help him. In this way there sprang up an immense "repairing" organization collectively described as orthopaedic surgery. It was divided into many sections. There was the central orthopaedic work concerned with problems of restoration of a non-special kind. There was, further, the work of facial reformation known as plastic surgery. This work achieved a series of triumphs which are among the brightest episodes of the war period. No disfigurement was regarded as hopeless, and by a series of carefully planned manœuvres results were achieved which had seemed beyond the scope of possibility. This department of restoration included surgeons, nurses, artists, sculptors and various workers in plastic materials who planned the "new faces" which it was the doctor's duty to create.

Another great department of this work was founded at Roehampton, where limbless men were dealt with. The problem here was the production of a suitable limb at a reasonable price, its accurate fitting and its subsequent care. At first very many difficulties were encountered, for no one possessed the necessary experience. The early limbs were much too heavy and were found by wearers to put a great strain on their energies. Moreover, all kinds of technical troubles arose. Finally, however, a light limb was devised and, under the Ministry of Pensions, standardized. This limb has the great advantage of being capable of manipulation by the muscles of the stump; shoulder action in lifting it is eliminated.

These various branches of orthopaedic surgery necessitated the employment of a great number of masseurs and of attendants. They also necessitated the training of surgeons and nurses in the special methods employed. It speaks for the success of the organization that at the end of the war there were expert staffs in every region of England. Moreover, the so-called manual curative workshops were conducted as a part of the orthopaedic surgery method. The idea was that a man who required to exercise a stiff limb might do this and at the same time learn a trade, *e.g.* by swinging a hammer instead of a club. So great was the success achieved that a curative workshop was soon to be found in proximity to each orthopaedic hospital. This was first suggested by ex-King Manoel of Portugal.

Equally important was the branch of restoration which gained the name of "medical orthopaedics"—the work on behalf of the soldier with broken nerves. The War Office took this matter in hand at a very early period and called to its help noted psychologists and psychotherapists. The result was a reëxamination of functional nervous disorders and the formation of a great department of army medicine. Instead of being branded as a coward the nerve-broken soldier was cared for and treated, and so in many cases saved from the loss of his reason. Here again the method employed was to take advantage of all the available knowledge and attempt to increase it by research work. There were practising side by side, in the military hospitals set apart for nerve cases, physicians of different schools of thought and even of opposite views. Yet so elastic was the organization that no difficulties arose. On the contrary, an immense stimulus to new work was afforded.

This vast organization of British army medical work grew up under the hands of Sir Alfred Keogh. His methods were simple but, as the event proved, invariably effective. He believed that the more complete the organization of the medical corps became the better was the effect exercised on the *moral* of the common soldier. Thus, not only was every effort made to secure personal health and protection against disease and injury, but even personal comfort and happiness became the doctor's business both in the line, in hospital and at the convalescent camps. The soldier, too, knew that if he was broken in mind or body all the resources of medicine would be exhausted over years to save him.

This great effort could never have been achieved had not Sir Alfred Keogh called to his aid the leaders of every branch of medicine and surgery and given them, so far as possible, a free hand. Nor could he have achieved what he did without the assistance of the Medical Research Committee. He saw that research work is as urgent in war as in peace; and he reaped great rewards for this foresight. Indeed, his organization was as strong on its constructive as on its executive side. (R. M. Wt.)

### III. Diseases in the World War

The medical diseases of the World War fall into two main groups. In the first are the neuroses or nervous disorders which resulted from the stress of active service, and in the second are the diseases which resulted from infection with disease-producing organisms. Whereas the former were infinitely more common than in any previous war, owing to the far greater strain to which the soldier was subjected as a result of modern methods of warfare, the latter were unexpectedly rare owing to the wonderful improvements in military hygiene, resulting from medical research in the comparatively short period of thirteen years which had elapsed between the conclusion of the South African War and the outbreak of the World War in Aug. 1914. While the neuroses opened up new and perplexing problems to the neurologist, the relative frequency of the various infectione differed greatly from that of previous campaigns and presented many subjects for research, which were studied with great enthusiasm and success, especially by the large body of British civilian medical officers who were called in to assist the regular R.A.M.C., whose hands were generally fully occupied with administrative details.

(*A.*) *War Neuroses.*—The frequency of neuroses in soldiers during the war compared with their comparative rarity in men in civil life was due to the exhaustion and emotional strain inseparable from active service. The exhaustion caused by long days of forced marching and strenuous fighting, followed by nights with little or no sleep, combined in some cases with insufficient food, and, especially in eastern campaigns, with a great variety of infections and exposure to extreme heat, naturally led to a more profound condition of nervous exhaustion or neurasthenia than is commonly seen in civil life. It was not, however, as frequent as might have been expected, as exhaustion was largely prevented by the intervals of rest and opportunities for relaxation, which became increasingly common as the war progressed and the need of adapting conditions to fit in with the psychology of the soldier was more fully understood by those in authority. At the same time the supply of food was almost invariably admirable, and there was a remarkable freedom from epidemic infections on a large scale, especially in France, owing to the excellence of the sanitary arrangements. More important perhaps than the actual production of neurasthenia was the increased liability to the development of hysteria and psychasthenia and the aggravation of incipient organic diseases, such as locomotor ataxia, general paralysis, and epilepsy.

Though a few fortunate individuals are born with a temperament which does not allow them to know what fear means, the vast majority, including many of the bravest, were terrified when they first approached the front line. Many men became accustomed to it

in time, though never to the horrors of a heavy bombardment, but sooner or later the exhaustion of active service often resulted in a gradual failure of the adaptation, so that not only the constitutionally timid—the martial misfits—but also some who had faced the life cheerfully for months or years broke down from the long-continued emotional strain.

The emotion of fear acted in three ways. In the martial misfit, who is by nature very suggestible, it gave rise at once to such physical symptoms as tremor, inability to speak and inability to move, which might be perpetuated by auto-suggestion as hysterical tremor, mutism and paralysis, the three together constituting one form of the condition often called shell-shock, though it rarely had anything to do with actual shell concussion. In other cases it resulted in a man passing into a dazed condition or stupor, which might lead him to wander from his post of duty and run risk of being court-martialled as a deserter. Finally, it might result in such a disturbance of the suprarenal and thyroid glands that a condition of continuous over-activity, with symptoms not unlike those of Graves's diseases (exophthalmic goitre), might follow.

The acute emotion caused by a single exceptionally terrifying experience sometimes led to such a change in an individual that he became for a time extremely liable to develop hysterical symptoms by suggestion, especially if the experience led to actual physical results. Thus, when a man was gassed he became temporarily unable to see or to speak owing to irritation of his eyes and his larynx, and he often vomited owing to irritation of his stomach. Any of these symptoms might be perpetuated by suggestion—hysterical blindness, inability to make any sound at all or more commonly inability to speak above a whisper, and vomiting being the respective sequels. If a man was blown up or buried, the loss of memory, headache, paralysis, deafness and convulsions which might result from the concussion of his brain were often perpetuated as hysterical symptoms long after the actual changes in the nervous system had so greatly diminished that the symptoms should have completely disappeared. After much study of the problems presented by these hysterical symptoms, which became increasingly frequent as the war progressed, psychotherapeutic methods, consisting of explanation, followed by persuasion and reëducation, were devised, which resulted in extraordinarily rapid recovery, the majority of cases, even after the symptoms had persisted for many months, being cured at a single sitting.

An exhausted officer, who was constitutionally unsuited to the life of a soldier, was more likely to develop psychasthenic symptoms than his men owing to his greater responsibility. He found it increasingly difficult to decide between two possible lines of action, and, when at last he had adopted one, he was full of doubt as to whether he had decided rightly. His power of concentration became deficient owing to his mental energy being largely taken up, without his fully realizing it, in repressing painful thoughts and conflicts, which he kept in the background of his mind in order to avoid distress. He consequently showed want of confidence in his actions, and became terrified that he would be unable to perform his duties in an emergency. His sense of duty urged him to carry on, but this was in acute conflict with his instinct of self-preservation, which urged him to get away from his hateful surroundings. In the daytime he might become suddenly overwhelmed with apparently causeless dread or terror, and he often found it difficult to fall asleep at night owing to the need of active thought to keep his distressing memories and conflicts buried. When at last he fell asleep and the controlling influence over his thoughts was relaxed, they came into consciousness in a distorted form as nightmares, with the result that he would wake in a condition of terror. The disturbed nights increased his exhaustion, until it was no longer possible for him to carry on with his duties. In early cases improvement rapidly followed a change to more favourable surroundings, especially if, instead of receiving the old-fashioned advice to forget his worries and occupy his mind with more pleasant matters, which it was totally impossible for him to do, he fell into the hands of an understanding medical officer, who, after gaining his confidence, helped him to solve his difficulties by freely discussing the thoughts he had been attempting to repress, however painful they might be. It was remarkable how rapidly persistent war nightmares, long-standing phobias and obsessions, and hitherto inexplicable emotional crises disappeared directly the patient understood the mental processes which had given rise to them.

(B.) *Infective Diseases:* (*a*) *Typhoid and Paratyphoid.*—In the South African War of 1899–1902, 60,000 cases of typhoid fever with 8,227 deaths occurred in the British army. In the far larger British army in France and Flanders only 4,571 cases of typhoid and paratyphoid fever occurred between Aug. 1914 and Nov. 1916, and the incidence of these diseases steadily diminished after the first few months of the war in spite of the steadily increasing size of the armies. This was almost entirely due to the remarkable success of the prophylactic inoculation with typhoid and, later on, with mixed typhoid and paratyphoid vaccines.

Paratyphoid fever was throughout much more common than typhoid fever both in France and in the East. There were probably 6,000 cases of paratyphoid fever among the 300,000 troops who were at Gallipoli, but the disease was comparatively rare in all other theatres of the war owing to more thorough protective inoculation after the end of 1915. The mortality in France was only 1·3%; in Gallipoli and Mesopotamia it was higher, but much below that of typhoid fever in the South African War.

(*b*) *Cerebro-spinal Fever.*—An outbreak of cerebro-spinal fever occurred among the Canadian troops on Salisbury Plain in 1915. A wide-spread and very fatal epidemic followed in many home-camps, and shortly afterwards the disease appeared in France. By the end of the year a number of cases developed on the eastern fronts. Investigation showed that the disease was caused by different types of the same bacteria, and when sera were introduced which were specific for each of these types, the very high initial mortality was greatly reduced, particularly when the disease was diagnosed early and serum given without delay.

(*c*) *Trench Fever.*—In the early summer of 1915 a form of fever was observed in the British army in France, in which two or more periods of raised temperature were separated by normal intervals of a few days. Similar cases were recognized with increasing frequency, and the disease soon became widely known as trench fever. Thousands of cases occurred in France and Flanders between April and Oct. 1915; it was comparatively rare in the winter, but increased again each spring. Trench fever did not occur in Gallipoli, but was introduced into Salonika by troops arriving from France in Dec. 1915. It was first recognized in the French army in May 1916 and in the Italian army in Oct. 1917, and it was common both in Germany and Austria from 1916 until the end of the war. The characteristic fever and painful shins of trench fever appear to constitute a disease which had never before been described, but it is conceivably identical with a disease mentioned by Hippocrates, Galen and Avicenna, in which relapses occurred at five-day intervals. The organism which causes trench fever was never isolated, but it was proved that the disease was spread solely by means of lice, which had fed on the blood of patients suffering from the disease and had then bitten other men. The frequency of trench fever thus varied with the prevalence of lice, and if they could be exterminated in an army, the disease would disappear as surely as the lice-borne typhus fever disappeared from the Serbian army when it was freed from lice in 1915. The disease had nothing to do with the trenches beyond the tendency for men to become lousy when herded closely together. It appears to have died out completely since the Armistice. Trench fever was never fatal, but it caused an enormous amount of sickness; it was indeed the only infection which gained any hold on the British army in France and Flanders, except for the wide-spread and very fatal influenza epidemic in the summer of 1918.

(*d*) *Dysentery.*—Amoebic dysentery, though common in tropical and sub-tropical countries, had never occurred in epidemic form in Europe until the summer of 1915, when nearly every soldier in the British army at Gallipoli suffered from it, and a large proportion of the thousand sick men who were daily removed from the peninsula during Aug. and Sept. had amoebic dysentery. It was less common in Oct., and the cold and rain in the great gale at the end of Nov. were quickly followed by the disappearance of the epidemic. But no sooner had amoebic dysentery abated than bacillary dysentery became increasingly frequent. Amoebic dysentery was probably conveyed to Gallipoli by troops coming from Egypt, where 13% of healthy natives harbour the amoeba of dysentery in their intestines and where large numbers of cases occurred among British soldiers. Amoebic dysentery was also very common in the army in Mesopotamia. A few cases occurred in France after the autumn of 1915 owing to the arrival from India, Morocco and Senegal, and later from Gallipoli, of men infested with the amoeba, though not actually suffering from dysentery. The disease was spread mainly by flies which swarmed in enormous numbers wherever there was any food and in every latrine. As flies always defecate each time they feed, amoebic cysts are deposited on jam and any other human food upon which they settle within twenty-four hours of feeding on the stools of dysenteric patients. During the hottest months in Mesopotamia flies were uncommon and dysentery very rare; when flies were present in enormous numbers—in the spring and autumn—dysentery became epidemic. As soon as it became recognized that the predominant form of dysentery on the Gallipoli peninsula was amoebic and men were treated with emetine from the moment of onset, the symptoms rapidly disappeared, but reinfection was common. It was the universal sickness caused by dysentery rather than the occasional death that mattered at Gallipoli, and it can be truly said that dysentery was one of the deciding factors in the failure of the campaign. Cases of inflammation and abscess of the liver due to the amoeba of dysentery continued to occur even three and four years after infection in men who had not been adequately treated.

The dysentery which has been common in armies on active service since the Peloponnesian War has probably always been of the bacillary variety. Out of 30,000 British troops who fought in the Crimea, 7,883 suffered from dysentery, and of these 2,143 died; in the South African War there were 38,103 cases with 1,342 deaths. Bacillary dysentery made its first appearance in the early weeks of the World War in East Prussia and Galicia and was brought to France by von Kluck's ill-fed and tired soldiers on their march on Paris. It was present on every front whenever the weather was hot, and caused an enormous amount of illness in Salonika, Mesopotamia and Palestine as well as in Gallipoli. The disease was spread by flies in the same way as amoebic dysentery.

The chief means of combating both forms of dysentery is to

destroy flies and to destroy or disinfect infective faeces directly they are passed. Anti-dysenteric serum was shown to be as valuable in the treatment of bacillary dysentery as emetine was for the amoebic form, but unfortunately the supplies of serum were totally inadequate, and in none of the eastern theatres was there any central bureau of information which could inform the scattered medical officers about recent advances in the treatment of the diseases they were called upon to fight. It is probable that in the future an anti-dysenteric vaccine will be produced which will have as powerful a protective action against bacillary dysentery as anti-typhoid vaccine has against typhoid fever, but very little satisfactory vaccine was available for use during the war.

(*e*) *Epidemic Jaundice.*—A mild form of jaundice was very common in the Gallipoli campaign between Aug. and Dec. 1915, and in Mesopotamia during the hot weather of 1916 and 1917. The symptoms were similar to those of the catarrhal jaundice, which occurs sporadically among civilians in peace-time, and the condition appears to have been of the same nature as the epidemics in the American Civil, Franco-Prussian and South African wars. It appears to have been due to infection with an organism allied to the bacillus of paratyphoid fever, and numerous investigations failed to reveal the presence of a spirochæte. The mortality was so low as to be almost negligible; many men continued on duty though jaundiced, especially at Gallipoli, but the majority were not fit until six or eight weeks had elapsed from the date of onset.

From the spring of 1916 until the end of the war an entirely different form of infective jaundice occurred among the troops of all the armies engaged in France and Flanders. It was caused by infection with a spirochæte, and was identical in nature with a disease which every year attacks between 3,000 and 4,000 miners in Japan. It is best described as spirochætal jaundice rather than by the older name of Weil's disease, as it was accurately observed amongst French soldiers by Larrey at Cairo during Napoleon's Egyptian campaign in 1800, and by numerous other French physicians before Weil's paper appeared in 1886. The spirochæte was discovered in rats caught in trenches in which the disease had occurred; the infection in rats is chronic, the organism being excreted in the urine, which is probably the source of infection in man. The disease could be prevented if adequate steps were taken to drain trenches and exterminate rats. The symptoms were much more severe than those of the bacillary jaundice of Gallipoli and Mesopotamia; the mortality, however, was only about 4% in the British army, though it was 13% in the German army and is about 30% in Japan.

(*f*) *Malaria.*—Malaria had the same effect on the operations in Macedonia that dysentery had in Gallipoli. Few men in the Salonikan army failed to become infected with malaria during the summer of 1916, and there is no doubt that throughout the campaign the mosquito was a far more formidable enemy than the Bulgar. Prophylaxis by means of quinine completely failed and it was found quite impossible to reduce the numbers of malaria-carrying mosquitos to any appreciable extent. The conscientious use of mosquito nets was, however, very effective. The disease was of a particularly virulent form, the mortality being exceptionally high. Even after the Armistice it proved a matter of great difficulty to exterminate malaria in men who were infected in the Struma valley.

The Mesopotamian army also suffered greatly from malaria but not quite to the same extent as the army in Macedonia. The disease was very common and very severe in the army in Persia. The number of cases in France was quite trivial, most cases being due to relapses in men who had been in one of the eastern theatres of war.

(*g*) *Infective Nephritis.*—Acute nephritis, or inflammation of the kidneys, is a comparatively rare disease in civil life. It does not appear to have been common in any previous campaign except the American Civil War, in which over 14,000 soldiers of the Northern armies were invalided for nephritis, and to a less extent in the Franco-Prussian War. A considerable number of cases occurred among British troops in France throughout the World War, and a slighter outbreak occurred in Gallipoli and Salonika. It appears to have been less prevalent among the French and still less among the Belgians. It was very common among the German and Austrian soldiers on every front, though not a single case was observed by German medical officers among the Turks. It was very rare among officers of all nationalities, and was never sufficiently common among the men to be of any real importance to the strength of the army, the maximum incidence (in Dec. 1916) being only 104 cases per 100,000. All attempts to discover the cause of the disease failed, but there appeared to be something about the conditions of life of the soldier, as distinct from those of the civilian, which made him specially liable to develop nephritis, as it never occurred among the civilian population or refugees of Belgium and France, who lived in the midst of soldiers and with many soldiers billeted on them. This was in striking contrast to the parallel incidences of most of the epidemic diseases among civilians and soldiers.

The mortality of the infective nephritis of soldiers is much lower than that of the ordinary nephritis of civil life, being approximately 1% in the early stages, though a few additional deaths probably occur from relapses some months after apparent recovery. Most patients recover well within a month, but the complete disappearance of symptoms was sometimes delayed for a year or even longer.

(*h*) *Soldier's Heart.*—Soldiers not infrequently suffer from symptoms due to functional circulatory disturbances during their period of training and still more often whilst on active service. In neither case do the symptoms differ from those which may occur among civilians, but their relative frequency has led to the adoption of the term "soldier's heart." The effect of active service on the heart was first studied during the American Civil War, and a great many valuable investigations were carried out during the World War.

Already by the end of May 1916, 2,503 out of the 33,919 soldiers (7·4%) invalided from the service since the beginning of the war had been discharged on account of "heart disease," and this proportion was maintained until the end.

Soldier's heart was most commonly caused by over-exertion, often associated with prolonged mental strain and insufficient sleep, acting on a heart and nervous system which were already weak before the war or which had become weakened on active service as a result of an infection or other form of poisoning. Some men are born with a circulation sufficient for ordinary purposes, but with insufficient reserve power for increased strain. They generally know their limitations, adopt a sedentary occupation in civil life, and do not indulge in out-of-door sports. Many of them break down during training, but even if they develop into efficient soldiers they are likely to develop cardiac symptoms on active service. Thus nearly 60% of men suffering from soldier's heart were recruited from sedentary occupations.

In most cases the symptoms developed during convalescence from some acute infection, such as typhoid and paratyphoid fever, epidemic bacillary dysentery as well as non-specific chronic diarrhoea, malaria and influenza. Excessive smoking was undoubtedly a contributory cause in many cases, and gassing was frequently followed by cardiac symptoms. In a small proportion of cases the excessive activity of the thyroid and suprarenal glands which results from prolonged mental strain was a further factor.

Over-exertion is a relative term. A well-trained man can do work which would be impossible in the early stages of his training and which again becomes impossible if his heart and nervous system are damaged by the poisons produced by an infection, excessive smoking or incursive activity of the thyroid gland. But in the absence of these factors a trained soldier rarely develops cardiac symptoms.

In addition to the effect of nerve-strain on the circulation through its influence on the thyroid and suprarenal glands, the nervous exhaustion or neurasthenia, which results from the combined effect of physical fatigue, mental strain and infection, gives rise to a condition of nervous irritability, which causes slight circulatory disturbances to produce palpitation and discomfort and pain in the region of the heart, although the actual condition is such that subjective symptoms would not occur in a man with a normal nervous system.

The commonly accepted official diagnosis of "D.A.H." or "disordered action of the heart" for soldier's heart is most undesirable, as it at once makes the patient believe that he has "heart disease." Some indifferent diagnosis such as "debility" would be preferable. Treatment by graduated exercise instead of prolonged rest in bed was almost invariably followed by rapid improvement if undertaken at a sufficiently early stage, and whenever the comparatively innocuous nature of the condition was widely recognized by medical officers most men suffering from "soldier's heart" were able to return to duty after a few weeks in special training camps. When, however, it was regarded as if it were due to a serious disease of the heart and treated for long periods in hospital, the outlook was much less hopeful, and many men were invalided from the service and became chronic invalids as a result.

(D.) *Heat-Stroke.*—Heat-stroke occurred very frequently among the British troops in Mesopotamia during the hot summer months. It did not in any way differ from the heat-stroke which sometimes occurs in India. In Mesopotamia it was, however, more common owing to the less favourable conditions of life.

During the earlier years of the campaign heat-stroke was very nearly always fatal, mainly owing to the lack of facilities for treatment. By 1917, however, great progress had been made both in prevention and treatment, and the proportion of recoveries was much increased. The most important precautions for avoiding heat-stroke were the provision of large quantities of cool drinking-water and of suitable clothing and equipment. Men suffering from other illnesses, such as malaria, sand-fly fever and gastro-intestinal disorders, were specially liable to fall victims to heat-stroke.

The disease was always dramatically sudden in onset, and usually within an hour the patient was completely unconscious and in convulsions. In untreated cases death occurred within a few hours with a body temperature of 110° or over. The one essential for treatment was found to be an ample supply of ice. The establishment of special heat-stroke stations in all camps and depots proved most effective in reducing mortality. Those who recovered, however, were seldom fit for further service in Mesopotamia and in most cases were eventually invalided to England. (A. F. Hu.)

## IV. Surgery During the War

Military surgery during the progress of the World War reached unexampled levels of efficiency and width of scope, and the general results attained exceeded any limits which had been anticipated. Yet this consummation was not arrived at

by a smooth and easy path, neither were the full fruits rapidly gathered. Experience indeed was but a repetition of that gained in all previous campaigns. In Aug. 1914 time had been allowed for collation and digestion of the observations made in the more recent wars, while in civil life progress in surgery had been continuous and considerable. Hence the military surgeon entered upon his duties with confidence in the methods at his disposal and with fair hope of eliminating more or less completely many of the mischances from which his predecessors had suffered. These anticipations were not promptly realized; in spite of the perfected technique which was considered to have been acquired in the general treatment of wounds, and the accurate knowledge which had accumulated as to the characters of the injuries inflicted by modern rifle bullets, it soon became evident that this war, like all its predecessors, would have to teach its own lessons. This experience depended chiefly upon two factors: (1) bullet wounds did not form the preponderating element, but were less frequent than those produced by fragments of shells and bombs, which latter were of a severity and extent scarcely conceived beforehand; (2) the forms of infection met with were more varied and virulent than those commonly dealt with.

Thus in the earlier stages of the war the entire field of surgery was necessarily dominated by the elementary but fundamental question of appropriate treatment of the mere wound, to an extent which materially prejudiced advance in the management of individual injuries. The actual starting-point of real advance was relegated almost to the pre-Listerian period, and a vast amount of past experience required to be repeated and controlled before a firm foundation for progress was established.

When definite principles had been laid down to guide the routine treatment of infected wounds, a second great question still demanded settlement: At what stage in relation to the fighting-line should the definite treatment of gunshot injuries be undertaken? The result of all previous experience had been to the effect that field hospitals were unsuitable for any but temporary measures except in the case of great urgency. The casualty clearing-stations, a recent introduction into the British establishment, were originally intended to act mainly as sorting and distributing centres, and it was laid down that the great bulk of the wounded men should be transferred to the stationary and general hospitals on the lines of communication.

A short time sufficed to prove this arrangement to be defective, since, in spite of the efficient means of transport which had been rapidly developed, it became evident that the primary treatment of the wound needed to be more radical than had been anticipated; when only provisional measures were adopted the patients were in little better condition for the procedure on their arrival at the stationary and general hospitals than if treatment had been entirely omitted. The progress of the infections, in fact, was far more rapid than any means of transport, and such preliminary steps as had been taken required to be repeated upon wounds already increased in extent, with very definite disadvantage to the patient. At this stage the settling-down of the form of warfare to a stationary character allowed for the development of the casualty clearing-station into a potential stationary hospital, while in addition it was found practicable to establish small advanced operating units still nearer to the front to deal with injuries to the abdomen, head, etc. To this development, and in great measure as a result of the bravery and efficiency of the bearers who brought in the wounded men, the whole of the advance in the primary treatment of gunshot injuries is referable. Such conditions may not often recur, but one result of the work done must remain and exert a permanent influence on military surgery. The efforts and firm convictions of a band of enthusiastic and capable surgeons demonstrated for all time that results of equal excellence can be obtained by the military as by the civil surgeon if only sufficient initiative, care and resolution be maintained. The bugbear of "the exigencies of warfare" has been in fact displaced from the commanding position which it has held heretofore.

*The Treatment of Wounds.*—At the outbreak of war it was generally held that the treatment of gunshot wounds should approximate itself in procedure to the methods in use in civil practice, purely aseptic measures being supplemented by the addition of some antiseptic medium in the case of open wounds fouled by contact with the clothing, the missile or the soil. It was believed that this addition should suffice at the primary dressing to check the progress of the initial infection. This view was founded upon experience gained in recent wars, in which the great majority of the injuries were inflicted by bullets of small calibre. It had been observed that many of these healed well even in the absence of any surgical aid, while the great majority closed without any serious accidents when protected by an occlusive dressing adjusted either by a bandage or some sort of adhesive such as collodion or mastisol. Too little attention indeed was given to the further observation that the comparatively rare shell wounds always suppurated even under the favourable conditions which attended the S. African War of 1899–1902. In the early days it was assumed that the ravages induced by infection were to be explained by the conditions then existing, such as the long distances the patients had to travel, the impossibility of sufficiently frequent changes of dressing, and the want of proper rest. The pernicious influence of these conditions is obvious, but it was rapidly grasped that they should not be held to be an insurmountable element of failure. An attempt was at once made to combat the primary infection more efficiently by mechanical procedures, consisting of free excision of bruised, soiled or devitalized tissue by the knife or the scissors, followed by drainage of all recesses of the wound by india-rubber tubes and a completely "open" method of treatment.

At this period two principles concerning the management of an open infected wound were freely debated. By Almroth Wright and his school it was maintained that the extinction of infection was most rapidly effected by attempting to increase the activity of the normal factors in the process of healing. The method adopted was called the "physiological or phylacogogic," and an endeavour to accomplish the desired aim was made by flooding the wound with a saline solution of a higher specific gravity than that of the fluids permeating the body tissues and thus to "draw" an abundant flow of lymph towards the free surface. By this means also the tissues were "lavaged" by a stream of lymph, the current of which flowed in a direction opposed to the spread of infection inwards. Later the "hypertonic" solution, while accomplishing this end, was found to check the migration of leucocytes to which Wright eventually ascribed the chief place in subduing the infection; hence at a certain stage in the course of healing an isotonic was substituted for the hypertonic solution.

The second school, influenced by the early work of Lister, retained allegiance to the use of antiseptic media of varying kinds. By many the hope was cherished that an agent might be discovered that would not only cleanse and disinfect the exposed surface of the wound, but would also penetrate the underlying infected tissue and thus hasten the natural process. This dream, emanating from an imperfect appreciation of the "preventive" nature of Lister's work, was not fulfilled. Nevertheless, the supporters of the antiseptic theory played a highly important part during the period of argument and uncertainty both as to principle and practice. The most important of the media employed consisted in perfected solutions of the hypochlorites, and certain anilin dyes, particularly flavine and brilliant green. It may fairly be stated that the application of an antiseptic to the wound, or in the dressing, in itself played a minor part, the real advance which followed depending not upon the antiseptic which was employed but upon the development of an efficient system. In the Carrel-Dakin system, although great importance was attributed to the hypochlorite solution, yet the success which it attained was really due to exact observation of the nature and course of the infection concerned, careful initial preparation of the wound, meticulous precaution against stagnation of infective material in recesses in the cavity, and the prevention of reinfection of the surface. It was the experience gained from the practice of this method in the treatment of compound fractures of the bones that clearly demonstrated the possibility of the

routine secondary closure of the accompanying open wound, an achievement only second to that of Lister in his early treatment of similar injuries. This result attained, the practicability of resort to secondary suture in most wounds was established.

Subsequent advance proved the practicability, under favourable conditions and environment, of primary closure of the compound fracture without the aid of any antiseptic medium. This ideal was reached by a rational extirpation of the infected tissue by mechanical means, followed by a sufficient period of rest to the patient and to the injured part.

The net result, therefore, of a period of strenuous work and argument was to reaffirm the principles with which surgeons were already acquainted at the commencement of the war: (1) that sterilization of living tissue can only be effected by the natural vital process; (2) that no chemical agent is known capable of penetrating the tissues of the body and destroying microörganisms which is not at the same time deleterious to the tissue itself, and that the sole means of procuring abortion in an infected portion of the body is radically to remove the infected tissue. Again, no novelty in principle was introduced by the practice of either the primary or secondary closure of compound fractures, or of wounds in general; the triumph consisted in the translation of these occasionally used methods within the limits of routine practice. It may be added that the method of secondary suture is to be regarded as the more valuable of the two, since it is but rarely that conditions will not allow its adoption, while in military surgery it is generally difficult to ensure the requirements essential to the success of primary suture. Paradoxical as these conclusions may appear, success was only gained after strenuous effort and the development of a technique and degree of judgment equal to those required for the most exacting operations in the entire realm of surgery.

*Nature of the Infections.*—It can hardly be said that any novel form of wound infection was discovered, but knowledge was extended in many directions. The hourly progress of mixed infections was investigated, and the vital tenacity of the different organisms determined, while a still more fruitful series of observations was made in the effort to determine the moment at which a wound with a fouled surface became an actually infected one. The result of the latter investigation allowed a general assumption to be made that during an interval of from four to eight hours the multiplication of organisms in their new environment was slow and penetration of the living tissues by them unlikely. Thus a definite time-limit was assigned, beyond which primary closure should not as a rule be attempted. It was shown that only the staphylococci and streptococci as a rule remained present in the terminal infection, and that of these the streptococcus was the more undesirable occupant of the wound. Further, the power of haemolysis possessed by some forms of streptococcus marked them out as the more dangerous to the progress of the wound and to the life of the patient.

The unusual frequency of anaërobic infections afforded opportunity for an extensive investigation of the microörganisms concerned, the special characters of the changes produced by each, also of the importance of symbiosis in these phenomena, thus accentuating the importance of suppuration in the development of such diseases as tetanus, or in the causation of gangrenous cellulitis.

Although acute traumatic gangrene was well known in civil practice, yet it seems doubtful whether it has played such a prominent part in any previous war. There is good evidence that it was rare in the American Revolutionary War, and in the S. African War it was certainly but very rarely met with. One very distinct advance was made in the treatment of the condition. It was observed that the spread of the infection tended to be limited by the fascial envelopes of the muscles, particularly in the case of *B. perfringens* (the organism which specially attacks the muscle fibres), and that, if the vitality of the muscle was lowered by cutting off its blood-supply, the entire muscle rarely escaped destruction. Hence the practice of complete excision of a muscle from within its sheath was introduced, and proved most successful in limiting the spread of the gangrene in the limb, especially when the long muscles were affected.

Little success attended any but the mechanical treatment of anaërobic gangrene, but the treatment of tetanus afforded one of the great triumphs of preventive medicine—in fact, the result attained must be placed upon a level with that reached in the preventive treatment of enteric fever. It was recognized at an early date that every breach of surface with which the intensively cultured soil of northern France had come in contact was potentially infected with *B. tetanus*. Hence it was laid down that in the case of every serious wound the man was to receive an injection of tetanus anti-toxin, and this [illegible] extended to every wound, and even to chilled [illegible] vesication had occurred.

Further, since the protection afforded by this measure is known to disappear rapidly, a second injection was given at the end of seven days, and in severe injuries at similar intervals for the succeeding two or three weeks. Again, in view of the known fact that *B. tetanus* may lie latent in a healed wound for indefinite periods, a prophylactic injection was administered to many of the patients in whom late secondary operations became necessary.

In the curative treatment of tetanus it cannot be claimed that any very important advance was made. The chief variation in method consisted in the administration of greatly increased doses of anti-toxin. While it remains doubtful whether much advantage was gained by this procedure, it was demonstrated that in some instances the dosage had previously been insufficient. In base hospitals in England, as a result of mainly intra-thecal injections, the average mortality of the disease was reduced from 57·7 % to 19 %. In France, where a more acute series of cases had to be dealt with, the reduction only reached equivalents of from 78·2 % to 67·4 %.

With regard to the route for the injections, many surgeons considered the spinal intra-thecal the best, but clinical observation does not appear to give strong support to this view, although experimental evidence from animals is adduced in its favour. Intra-muscular injections probably gave the most consistent results, while subcutaneous injections proved sufficient for prophylactic purposes.

In connexion with the prophylactic treatment, mention should be made of the fact that, if it failed to prevent, it was still capable of modifying the disease, and local phenomena were much more common than would otherwise have been the case. Except in the splanchnic form, although the local might be only the commencement of a general attack, the prognosis was much better.

*Shock and Haemorrhage.*—The circumstances attendant on active warfare, such as anxiety, heated and ill-controlled emotions, fatigue, want of sleep, hunger and thirst, exposure to cold and wet and, lastly, severe injury, often combined with loss of blood and pain, afford every condition with which we are accustomed to associate the occurrence of shock. In spite of the arduous investigations undertaken it can hardly be said that the actual explanation of the phenomena has been unveiled. Observations, however, tended to negative certain theories, such as those of acapnia, acidosis, suprarenal incompetence, exhaustion of the vasomotor centres or cardiac weakness, as a primary factor. Hence we must still be content vaguely to regard the phenomena of shock as nervous in origin. In one particular a definite advance was made in the realization that the fall in blood-pressure, which is so prominent a feature in the condition of shock, is strictly comparable to the fall attendant on haemorrhage, the volume of blood within the arterial system being reduced not by external escape from the open vessels but as a result of stagnation in the capillaries. The older theory of stagnation in the visceral veins of the thorax and abdomen was not only exploded by experimental observation, but its error was also demonstrated by the appearances observed during the performance of numerous operations for visceral injuries during the period in which the state of shock was in some degree persisting.

The condition known as "secondary shock," in which the phenomena develop hours or even days after the initial injury, perhaps after primary shock has already been recovered from, had since the Listerian era been regarded as an evidence of toxaemia. The similarity was well illustrated in the cases of acute toxaemia in connexion with anaërobic infections, with which the war made everybody familiar. The experimental work of Dale and others on the action of histamine when introduced into the circulation of animals led to an investigation which seems to prove that the phenomena of shock may be produced by absorption of the metabolic products resulting from the mechanical destruction of muscle fibre, a common result of gunshot injuries.

The outcome of the observations made was to show that the first principle in combating shock is to attack the most prominent of its phenomena, *i.e.* lowered blood-pressure. The effect of infusions of normal saline solution for this object was known to be evanescent, and successful attempts to prolong the effect and at the same time to diminish the volume of fluid required were made by adding a colloid constituent to the solution. In order to place the patients under the most favourable conditions possible, a heating-system was added to the ambulances, and special resuscitation wards were equipped, so that the more simple means, such as the application of warmth, the administration of fluids by the mouth or *per rectum*, and the ensurance of absolute rest, were facilitated. When necessary, these methods were supplemented by infusion of the "gum-saline" fluid of Bayliss. This solution contained sufficient of the colloid (6 %) to increase its viscosity and endow it with an osmotic pressure comparable to that depending upon the colloid constituent of normal blood. The saline constituent (1·5 to 2 %) of bicarbonate of sodium was introduced to counteract the decreased alkalinity of the blood occurring in shock and to prevent haemolysis.

The same solution was employed in the treatment of the slighter cases of haemorrhage. Serious cases were dealt with by the replacement of whole blood. The indication for the latter method was sought for in persistence of a blood-pressure as low as 80 mm. of mercury. In primary haemorrhage estimation of the haemoglobin content of the blood was considered too elaborate a method and unsuitable for use from want of time.

Transfusion became common in consequence of the ease with which donors of blood could be secured from amongst the soldiers. The older method of direct transfusion was found inconvenient from an operative point of view, and unsatisfactory from the fact that it is difficult to estimate the amount of blood which has actually passed from donor to recipient. Hence blood was more commonly collected from the donor into a glass vessel coated with paraffin to prevent coagulation (Kimpton's tube), and thence transferred to the recipient. To meet difficulties resulting from premature coagulation, the blood was sometimes drawn into a vessel containing a solution of citrate of sodium, since it had been found that the addition of 0·5% of this salt to the blood had no deleterious action. In the later stages of the war it was found practicable, in view of the possibility of having to transfuse a large number of men in an emergency, to substitute a fluid containing preserved red blood-corpuscles suspended in a sufficient volume of a 2·5% solution of gelatine to bring the total volume into consonance with that of the whole blood originally drawn from the veins of the donor.

To meet the well-known difficulty that individuals fall into definite classes in regard to their capacity to receive the blood of others with safety, a simple classification was arrived at by means of agglutination tests. Thus suitable donors were previously selected and were always available. Four groups were differentiated, of which it was determined that those belonging to the first (8%) could take blood from either of the remaining three groups. Of the other three, the second group (40%), the third group (12%), and the fourth group (40%) could receive blood only from individuals belonging either to their own group or to the fourth group.

*Special Surgery.*—One great principle that in the past has governed the application of a ligature to the great arteries of the limbs received considerable modification. It had always been held that, when a main artery was tied, the conservation of the accompanying vein was of the utmost importance for the preservation of the vitality of the limb affected. Experience gained from observation of a long series of cases, in which both vessels were implicated, demonstrated that not only was the integrity of the vein of no vital importance, but that the immediate results were more favourable when both vessels were occluded simultaneously and a better balance maintained between the capacity of the modified arterial and venous systems. Experimental investigation supported this clinical experience, since it was shown that the blood-pressure in the affected portion of the limb was maintained at a higher level.

The substitution of local repair of the wounded walls of arteries for complete obliteration of the vessel by ligature made little progress until the general methods of wound treatment allowed such operations to be made without fear of subsequent infection. In the later years of the war steady progress was made in this direction, and it was shown that ideal results might be obtained, and further that even should the local patency of the vessel not be maintained, yet the result was at any rate in no way inferior to that following successful ligature of the vessel.

The general treatment of compound fractures has been already alluded to, but beyond improvement in the management of the wound, considerable modification took place in the nature of the means adopted to ensure good position of the bones. The change depended on the general introduction of the metal wire splints of Hugh Owen Thomas. These were found capable of adaptation to the great majority of all fractures of the limbs, and also equally suitable for employment in the front line and in base hospitals. It is of interest to note that one of the main principles of their originator was found capable of modification, as well as variations in construction. Fixed extension did not prove convenient or easy of application in military practice, and the substitution of weight-and-pulley extension, or the employment of the weight of the patient's body as a means of counter-extension, was widely and successfully resorted to. In no department of surgery was more initiative and ingenuity shown than in the numerous devices designed to meet the needs of individual cases or different regions of the body.

Infected wounds involving the articulations maintained the reputation of this form of injury as a source of difficulty and anxiety. One heterodox principle was propounded. Absolute rest to the joint has always been regarded as the surest means of checking the spread of infection, but success attended resort to a method in which active movements of an open articulation were commenced from the outset. It was claimed, and with some justice, that this method favoured the escape of infective exudation from the cavity of the articulation, and that the formation of adhesions and ultimate restriction of the normal movements were minimised. It is perhaps too early to give a definite opinion on this subject.

As regards injuries to the nervous system, it suffices here to say that the advances made in the more accurate knowledge of localization of function in the different parts of the brain and the spinal cord, and increased knowledge of the mode and progress of regeneration in wounded peripheral nerves, took a more important place than those in technical treatment of the injuries.

The book of knowledge concerning the possibilities of thoracic surgery (*see* HEART AND LUNG SURGERY) may be said to have been opened up by the experience of the war. It was proved upon an extensive scale that the mere laying-open of the great serous sacs of the chest was not the dangerous procedure that had been widely assumed, and that, as Sir W. MacEwen had already demonstrated, no special artificial arrangements are necessary to maintain the normal intra-thoracic pressure during operations. Appreciation of this fundamental fact opened the way to free primary treatment of a large number of thoracic injuries which had formerly proved rapidly fatal not from the hopelessness of the actual injury but from the results of the infection which commonly followed it in consequence of insufficiency in boldness of surgical attack. Thus the way was cleared for dealing with intra-thoracic haemorrhage and its complications, wounds of the lung, retained fragments of infected foreign bodies, and even for dealing on rational lines with wounds of the heart. Of scarcely less consequence than these visceral operations were those rendered possible for removal of foreign bodies from the mediastina, a fruitful source of immediate danger, and of intractable fistula-formation at a later date. It is impossible to estimate how widely this new field of surgery may be exploited in the civil practice of the future.

The technique of the surgery of abdominal injuries had been already so highly developed as to call only for judgment and initiative to elevate military practice to the same level that had been reached in civil life. The difficulties which required to be surmounted were partly administrative, depending on the all-important element of time and the ensurance of as near an approximation as possible to the golden interval of six hours between injury and operation; partly dependent upon the severity of the injuries themselves. Both were overcome, and perhaps the most satisfactory feature of the result is seen in the increased tendency to conservancy in the extent of the operations—the effort to repair rather than to excise the injured part. The most striking in a series of successes was that attained in the treatment of severe abdomino-thoracic injuries, which had previously been regarded as beyond legitimate surgical intervention.

The experience gained during the war is likely to influence the future of surgical practice mainly in two directions. In the first place, the intimate personal association of workers in the branches of pure science ancillary to the practice of the art of medicine with the practical application of the principles laid down by them demonstrated the fruitfulness of this combination and its capacity to lead to rapid advance in elucidation of the problems constantly confronting the medical practitioner. Secondly, the assemblage of vast numbers of crippled men brought forcibly before the medical profession and the public the waste in national power which results from impairment or defect in physical capacity amongst a whole population, and accentuated the fact that in civil life circumstances had not been favourable for following up continuously the history and results of many common injuries. Hence surgeons who in the past had busied themselves particularly in the treatment of acquired defects and deformities extended the scope of their activities to preventive effort, and as a consequence greatly increased facilities have been provided for continuous treatment. (G. H. M.)

**MEDICINE, INTERNATIONAL.**—A decision of considerable importance in matters pertaining to international health was taken by the Assembly of the League of Nations at its first meeting held at Geneva in December 1920, when the following resolution was adopted:—

"In pursuance of Articles 23 (*f*), 24 and 25 of the Covenant of the League of Nations, and in order to facilitate the discharge by the League of Nations of the responsibilities which may be placed upon it by provisions of the various Treaties of Peace, the Assembly of the League of Nations resolves as follows:—

"That a permanent International Health Organization be established as part of the organization of the League of Nations."

Article 23 (*f*) of the Covenant of the League of Nations, embodied in the Treaty of Versailles, contains these words:—

"Subject to, and in accordance with, the provisions of international conventions at present existing, or hereafter to be agreed upon, the members of the League will endeavour to take steps in matters of international concern for the prevention and control of disease."

Articles 24 and 25 of the Covenant refer to the necessity of arrangements being made for carrying out the above principle in so far as it affects existing international health bureaux and voluntary international Red Cross societies.

The functions of the organization are as follows:—

(*a*) To advise the League of Nations in matters affecting health.

(*b*) To bring administrative health authorities in different countries into closer relationship with each other.

(*c*) To organise means of more rapid interchange of information on matters where immediate precautions against disease may be required (e.g. epidemics) and to simplify methods for acting rapidly on such information where it affects more than one country.

(*d*) To furnish a ready organization for securing or revising necessary international agreements for administrative action in matters of health and more particularly for examining those subjects which it is proposed to bring before the Standing and General Committees, with a view to international conventions.

(*e*) In regard to measures for the protection of the worker against sickness, disease, and injury arising out of his employment, which falls within the province of the International Labour Organization, the International Health Organization will coöperate with and assist the International Labour Organization, it being understood that the International Labour Organization will on its side act in consultation with the International Health Organization in regard to all health matters.

(*f*) To confer and coöperate with international Red Cross societies and other similar societies.

(*g*) To advise, when requested, other voluntary organizations in health matters of international concern.

(*h*) To organize missions in connexion with matters of health at the request of the League of Nations with the concurrence of the countries affected.

Underlying the various functions, as detailed, is the important principle that this newly created international health organization will "deal with such matters as affect individual countries only in their relation to other countries." This last phrase clearly indicates and defines the international aspect as opposed to any interference with the internal health organization of any individual nation. These functions were in their main outline drafted in London in April 1920, at an international health conference convened by the British Minister of Health, and subsequently submitted to the Council of the League of Nations for approval; such approval was granted by the Council at the meeting held at San Sebastian.

The machinery so far outlined for the new health organization consists of the following three departments: a general committee, a standing or executive committee, and an international health office or secretariat. The general committee was to consist of: (*a*) the delegates or their successors appointed to the Office International d'Hygiène Publique by the various signatory Powers to the international agreement drawn up at Rome in 1907; (*b*) other delegates appointed by countries not included in the Rome agreement, but who had become members of the League of Nations; (*c*) the medical secretary. This committee was to meet at least once a year at its headquarters in Paris, namely the Office International d'Hygiène Publique; it would appoint its own president and sub-committees and draw up its own constitution. Any member of the committee was empowered to call in the assistance of technical advisers, with no power to vote except when acting as deputy in the absence of the delegate he represents and only after due notice of the change has been sent to the president in writing. The main function of this committee was to receive full reports of the standing or executive committee and of all sub-committees.

The standing or executive committee was to consist of: (*a*) delegates of the States permanently represented on the Council of the League of Nations; (*b*) the president and five members of the general committee; (*c*) a representative of the League of Red Cross Societies; (*d*) a representative chosen by the governing body of the Labour Conference. This committee was to elect its own chairman and sub-committees, and meet not less than four times a year, and oftener as occasion required; the members were to be elected for a period of three years, and then be eligible for reëlection. The committee was empowered to draw up new conventions and revise old ones and render all its reports to the general committee. The International Health Bureau, the headquarters of the League of Nations, was to include the medical secretary, appointed by the standing committee, and directly responsible to it for such duties as it might assign. The medical secretary is entitled to attend all committees or sub-committees and to have the right of direct access to the secretary-general of the League and to communicate with the various national health organizations. The personnel of the bureau was to consist as far as possible of persons of different nationalities, all appointed by the standing committee on the nomination of the medical secretary. The medical secretary was to prepare in advance an annual budget for the approval of the standing committee and be responsible to the secretary-general of the League for all expenditure he might incur. The League of Nations was to provide all approved expenditure.

It will readily be agreed that the organization above outlined indicates great possibilities for the advancement of international public health; such machinery as is proposed should be capable of effecting a much-needed coördination among the individual nations, especially in such matters as shipping hygiene, port sanitation, etc., but how far the new organization will prove an advance on the work carried out by the various international health congresses held periodically at different centres will depend in some measure on the capabilities of the personnel to be appointed for the control of the new machine. It is greatly desired that the health organization of the League of Nations shall prove to be something more than an international bureau for the collecting and transmitting of health statistics.

Important as is the consideration of the various points of contact among individual nations in matters pertaining to general sanitation, yet there lies before the League of Nations the larger function of influencing the health of the people in the various countries in matters pertaining to the prevention of disease. Popular educational propaganda for the dissemination of knowledge in hygiene is likely to be more effective in raising the general standard of health of a people than the more tedious method of "patchy" and intermittent legislation. The "will to health" has to be quickened in the individual citizen by means of education, and one of the most hopeful elements in the new organization is the proposal to work in coöperation with voluntary organizations, which are more likely to be effective in carrying out educational health propaganda than when such is attempted by an official state organization.

One other aspect of the new organization that is suggestive of great possibilities is the fact that International Labour is to be represented on the standing or executive committee. The whole question of industrial hygiene as it affects the health and welfare of the worker is thus likely to receive that degree of attention which is so much needed. (N. B.)

**MEDINA** (*see* 18.64).—Before the World War, Medina was less known to Europeans than Mecca, although it was described by the earlier travellers, Burckhardt and Burton, and by Wavell (who visited it in 1908) as late as 1912. Much new information regarding existing conditions in the city was obtained as a result of the war operations.

A Turkish staff map of the environs of Medina, on the 1:50,000 scale, captured after the surrender,—the first map available since Burton's sketch made about 70 years ago,—shows the plan and disposition of the city, and photographs seized from the Turks revealed for the first time the nature and character of some of its buildings. The dimensions of the city were overestimated by earlier writers, the walls actually measuring not more than 1½ m. in circumference, with the longest diameter a little over ½ m. E. and W. The Hejaz railway has its terminal station outside the city walls at the Bab el 'Ambari, the gate on the S.W. through which runs the road to Yambo'. During the war a branch was carried from the main line, through a breach in the walls on the N.W. side, to the outskirts of the *Haram*, or Great Mosque, which was used as a munition store and intended to serve as an inner citadel in case of siege.

At the outbreak of the revolt in June 1916 the Arabs, unable to take the city by assault, withdrew and began a blockade which—as they were unwilling to bombard the city for fear of damage to the holy places and refused to cut the water-supply conduit—lasted until the Turks surrendered the city in Jan. 1919. In 1917 Fakhri Pasha, commander of the garrison, devised a scheme for the rebuilding and modernization of Medina, but all that happened was the destruction of a great number of houses for the sake of the beams and woodwork to feed the railway locomotives. Extensive palm plantations outside the walls, E. and N.E., were also ravaged for the same purpose. Large palm-gardens which formerly occupied much space within the walls were, in great part, built over, and the Barr el Manakha, or central open space, was encroached upon.

Before the World War the normal resident population was estimated at 40,000, of whom a large proportion were aliens who had settled after pilgrimage. The Turks deported about three-quarters of the inhabitants during the blockade, and, allowing for further decrease by disease, the population in 1920 was well under 10,000.

For plan, see ARABIA.

**MEHTA, SIR PHEROZESHAH MERWANJI** (1845–1915), Indian Moderate leader and municipal reformer, was the son of a Bombay merchant. Educated at the Elphinstone College, he

was the first Parsi M.A. of Bombay University, and coming to London to read at Lincoln's Inn was also the first Parsi to be called (1868) to the bar. With Dadabhai Naoroji he founded the organization which grew into the present East India Association. Returning to Bombay he rapidly made a name as an advocate and built up a fortune at the bar. Appointed in 1869 as Justice of the Peace, to participate in municipal affairs, he eagerly promoted the reform of civic administration begun in 1872, from which date he served on the new Bombay Corporation till his death. Through these 43 years he exercised wisely an extraordinary personal ascendency in that body and was four times president. He was also the dominant non-official figure in the Bombay Legislature, where he served for over 30 years. He represented its non-official members on the Supreme Legislature for three triennial terms to 1902, when he made way for G. K. Gokhale. One of the founders of the Indian National Congress, he presided at the Calcutta session of 1890. A stout opponent of violent methods, he did perhaps more than anyone else to stave off the complete triumph the extreme section in the Congress secured soon after his death. Most influential in the affairs of the Bombay University, he was in the last few months of his life vice-chancellor. A great orator, with remarkable gifts for managing men, his steadfast devotion to local and provincial reform and progress, while not irresponsive to wider calls, had a most valuable influence in moulding nascent Indian public life. Created a C.I.E. in 1894, he was advanced to the knighthood of the Order 10 years later. In the last year of his life, in spite of declining health, he threw his great influence strongly on the side of full Indian coöperation with the rest of the Empire in the World War. He died in Bombay Nov. 5 1915.

See the political biography by H. P. Mody (2 vols. 1921). Much light is thrown on Mehta's services to his native city in *Rise and Growth of Bombay Municipal Government* (1913), by his most intimate friend and co-worker, Sir Dinshaw Wacha. (F. H. Br.)

**MEIGHEN, ARTHUR** (1874– ), Canadian statesman, was born June 16 1874 at Anderson, Perth co., Ontario. After studying law, he practised for some years in Portage la Prairie, Manitoba. He was elected to the Canadian House of Commons in the general election of 1908, and was reëlected in 1911 and 1917. In 1913 he was appointed Solicitor-General in the Borden administration and in 1915 was sworn of the Privy Council for Canada. He became Secretary of State and Minister of Mines in 1917, and the same year was made Minister of the Interior and Superintendent-General for Indian Affairs. In 1918 he went to England with the Prime Minister, Sir Robert Borden, to attend the Imperial Conference. Following the retirement of Sir Robert Borden in 1919 he was chosen to succeed him as leader of the Union Government. He became Prime Minister and Secretary of State for External Affairs July 10 1920, and was appointed a member of the King's Privy Council in October of the same year. He attended the conference of Prime Ministers in London in June 1921. But he resigned office on the heavy defeat of his party at the elections in December.

**MELBA, MADAME** [NELLIE PORTER ARMSTRONG] (1859– ), British singer (*see* 18.90), was the organizer of many charitable efforts during the World War, and collected considerable sums for war charities. In 1918 she was created D.B.E.

**MELDOLA, RAPHAEL** (1849–1915), British chemist, was born at Islington July 19 1849. Educated at the Royal School of Mines, he became a lecturer at the Royal College of Science, South Kensington, and subsequently professor of chemistry at Finsbury Technical College in 1885, and did valuable work in connexion with the manufacture of coal-tar dyes (*see* 3.82 and 19.168). He was also interested in biological questions, such as the colouring of butterflies and animals (*see* 6.733). He died in London Nov. 16 1915.

See *Raphael Meldola; Reminiscences of his worth and work by those who knew him.* Edited by James Marchant (1916).

**MELLON, ANDREW WILLIAM** (1855– ), American banker and public official, was born in Pittsburgh, Pa., March 24 1855. After graduating from the university of Pittsburgh he entered the banking house of Thomas Mellon & Sons and later became a partner. The business developed into three strong institutions, the Mellon National Bank, the Union Trust Company, and the Union Savings Bank, all of Pittsburgh. Mr. Mellon was elected president of the first mentioned in 1902, and was vice-president of the other two. In the 'eighties he was interested in the development of the coal, coke and iron industry of Western Pennsylvania and was often associated in various enterprises with Henry C. Frick. He founded the town of Donora, Pa., and established a large steel mill there. He built the first independent pipe line, in competition with the Standard Oil Co., through Pennsylvania. He was a director in numerous corporations, and was a conservative Republican, opposing the League of Nations. In 1921 he was appointed Secretary of the Treasury in the Cabinet of President Harding.

**MENDELISM** (*see* 18.115).—The progress in physiological science made possible by Mendelian methods is described in the articles GENETICS and SEX. In the present article the influence of those discoveries on the development of biological thought and their application to the practice of breeding are considered.

(1) *Analysis.*—Modern genetics introduces into biology a factorial or analytical conception of organisms, which are now recognized as largely possessing attributes behaving as units and as such capable of being detached and transferred to any other type with which cross-breeding can be effected. The limits governing this principle of segregation and recombination are still undetermined.

(2) *Phenotype and Genotype.*—In former considerations of biological problems no account was taken of the consequences of the fact that each of the higher organisms is, in modern language, *diploid*, that is to say, a double structure containing factorial contributions derived respectively from the *haploid* or simple male and female cells which in fertilization united to produce it. Since some of these factors inhibit the effect of others, and since some give no sign of their presence in the organism unless other complementary elements are also present, the appearance of an organism is an imperfect guide to its genetic potentialities. We have thus to distinguish the organism as it outwardly appears to be from that which it actually is by genetic composition, a distinction which Johannsen has conveniently expressed by the use of the terms *phenotype* for the former and *genotype* for the latter. Systematic or classificatory works, both zoölogical and botanical, abound with errors arising from want of appreciation of this fundamental distinction, which must constantly be remembered, especially, for instance, whenever the significance of varietal or intermediate forms has to be estimated.

(3) *Variability.*—Evidence formerly regarded as proof of abundant contemporary variability in the species of animals and plants must be submitted to searching tests before it can be so accepted. Observations of variability once deemed adequate are now seen to be capable of quite different constructions. Proof that an observed departure from type is a contemporary genetic variation can only be obtained in exceptional cases which have been critically observed under experimental conditions. Putative variation is commonly nothing but the recurrence of a recessive form, or the emergence of some other segregant, from a stock genetically impure; more often still the direct product of a cross. The existence, therefore, of a multitude of varietal forms, so far from simply providing a convenient basis upon which a theory of the evolution of species can be erected, becomes itself an antecedent problem; and instead of asking, as they used to do, how the species have been built up out of the varieties, biologists are rather concerned to discover whence and by what process these variations have come to exist. The belief that substantial genetic change commonly accrues by summation of impalpable differences has been generally abandoned as devoid of evidential foundation. Such differences are mostly fluctuational, largely dependent on circumstance rather than on genetical units, and hence not transmissible. Summation, when a genuine phenomenon, is a consequence of purification or the attainment of homozygosis. The idea that a characteristic could in any other way increase as a result of selection is out of place in an exact or even a logical science.

(4) *Variation by Loss and by Addition.*—Whether the evidences of authentic variation remaining after the deduction of spurious testimony has been made suffice as a basis of evolutionary theory has been questioned by competent naturalists. Lotsy, for example, maintains that we have no proof of contemporary variation arising otherwise than as a consequence of crossing; and apart from such extreme pronouncements it is noticeable that as regards varieties of animals and plants anciently domesticated, modern authorities usually incline to ascribe a multiple origin even for forms like wheat, the fowls, pigeons, sheep, horses, etc., which used formerly to pass for derivatives from single types, a belief which is now felt to be inconsistent with what is known of the limits of variability. Distinction must be made between recessive and dominant variations, arising respectively by loss and by addition. As regards recessive variations arising by loss of elements few will doubt the adequacy of the records (*e.g.* in the sweet pea, *Primula sinensis*, etc.). As regards the *de novo* appearance of dominant characters the evidence is less abundant. Morgan and the American geneticists have made prominent several instances of this kind in *Drosophila* (fruit fly), of which the spontaneous origin of "eosin" (a new and peculiar pink) eyes in a white-eyed strain may be cited. Admitting provisionally these examples as free from objection they are nevertheless extraordinary events and not common occurrences. Were the dominant in question one already familiar we should hesitate to believe in its spontaneous origin. That a pea genetically wrinkled, having the characteristic starch of the wrinkled varieties, should without crossing produce a variety with "round" starch-grains would in modern lights appear not much less improbable than the spontaneous generation of life.

But, as explained in the article GENETICS, nothing absolutely forbids us from inverting the representation of positive and negative factors by extension of the conception of inhibitors of which many are familiarly known; so that we may express the apparent addition of a new element as a loss of one which when present had repressed the new attribute. This symbolism, though admittedly objectionable when dominance is complete, does without strain apply to all cases in which the heterozygote is intermediate, and a large range of alleged new dominants can be covered. In so far as this conception applies, evolution is conceived of as a process of unpacking, a progress consisting in the loss of component elements.

(5) *Mutation.*—The term *mutation* introduced by de Vries is now generally accepted to denote definite genetical variations which are sensibly discontinuous. Though contemporary examples which satisfy all tests are not abundant, there is no question that they occur and have occurred in most of the forms of life. They are indeed part of the occasional experience of most breeders of animals and plants. The special example, the Oenotheras, on which de Vries mainly founded his own theory was singularly unfortunate, and must, as explained in the article GENETICS, be now discarded as inapplicable. Mendelian analysis was only lately made known and the group of discoveries comprised in the term genetics were in an incipient stage; nor had the criteria of genetic purity, which must be applied to a parental form before the production of new types from it can be accepted as proof of original mutation, been clearly established. The Oenotheras which produce the presumed mutations are now proved to be no pure genotypes, and the suggestion that they were in a "period of mutation" arose from a misunderstanding of the nature and consequences of heterozygosis.

(6) *Inter-specific Sterility.*—The new forms whose productions we witness are never new species. In *Primula sinensis* about 20 pairs of factorial differences have been determined, which in their several combinations present an amazing polymorphism. A systematist, if he met these forms in nature, might and probably would quite justifiably take many of them for distinct species. But interbred, they and their products are perfectly fertile. Polymorphism like this, even in a state of nature, far more abundant and far greater than the evolutionists of the last century imagined, yet it avails us little as material out of which true specific differences can be supposed to develop. The conspicuous defect in the evidence for the origin of species by common descent remains. Though much is known as to the incidence of variation, not rarely of a magnitude which might naturally be claimed as constituting specific difference, no one has yet raised types from a common origin which when interbred produce sterility of the kind and degree which is one of the commonest attributes of crosses between natural species. By whatever concatenation of arguments theories of evolution have been constructed, that most essential link has never been supplied. The lapse of time is occasionally invoked in the hope of rectifying this and similar evidential defects, a strain which has been maintained distinct for a long period being thought more likely to show interracial sterility when crossed with its progenitor than one newly separated. Reasoning of this kind, plausible enough in scholastic days, is not acceptable in an age of chemistry, nor may we suppose that that which is never begun will be attained by mere effluxion of time. The more genetical experience extends, the more serious does this hiatus in the evidence become.

(7) *Evolution.*—In allusion to this and other difficulties, which genetic research has forced into prominence, the question is sometimes asked whether the theory of evolution holds its place so firmly as it did, or, more crudely put, whether Mendelian discovery has not "upset Darwinism." It should therefore be stated explicitly that in spite of all the objections with which the doctrine of the origin of species by descent is now seen to be beset—objections of which the strength is far more clearly known than before—and though as to the manner by which new species have come into existence geneticists adopt for the most part an agnostic attitude, yet all agree that the lines of argument converging to support the theory of common origin are so forcible and so many that no alternative can be entertained. The geological record is conclusive. To take one most cogent instance: if Angiosperms had existed in the carboniferous age their remains must have been preserved; therefore Angiosperms have arisen since that time, and we cannot conceive whence they came if not by descent from the preëxisting plants. Common descent, though rarely if ever a proposition demonstrable in any detail, ranks as an axiom. For Darwin and any other evolutionist before or after him this is a concession of the main claim. Parts of the apparatus by which the validity of that claim was enhanced have fallen into desuetude. In particular the modern geneticist assigns to *natural selection* a subordinate and inconsiderable *rôle*. Organisms are to be considered as coördinated systems. That each particular structure or instinct comprised in the system, which shows permanence or definiteness, makes a contribution to the success of the system equivalent to the cost of its production is recognized as a fallacy. We are also reluctant to apply to the interrelations of the collective properties of organisms arguments which would be out of place in similar considerations of the attributes of unorganized substances. We no more look for utility in the details of a peacock's feather than in the iridescence of a Roman bottle or in the regularity of basaltic prisms.

(8) *Adaptation.*—It is not merely in regard to the mode by which species have arisen that agnosticism has prevailed. While unwilling to accept adaptation, with Darwin, as a summation of happy accidents, we have no alternative to offer, nor is there in the recent attempts of various experimenters to find that organisms transmit to their posterity structural emendations in response to parental experience anything which sensibly alleviates the difficulty. Most of these claims are obviously faulty and few require serious notice.

Each step in the progress of this branch of science has rather compelled the recognition of genetic determinism; and the hope that by change in the conditions of life or by any external influences significant alteration can be induced in succeeding generations, whether of organisms amenable to experiment or of the human population, must be abandoned.

(9) *Classification.*—The full implications of factorial analysis in relation to biological classification are not yet appreciated. The fundamental idea of the systematist, that animals and plants can be grouped into species, and that the distinctions between species are of a different order from those characteristic of vari-

eties, is now scarcely open to question. Nevertheless the belief held very widely by systematists, that certain classes of differences are important as being more fixed, and others trivial as being more liable to variation, is scarcely consistent with genetical knowledge. The frequency and amplitude of variation and the perfection of segregation must be empirically determined for the various organisms and for the various characters. No general rules can be predicated. Anthropologists, for example, are accustomed to regard special features of anatomy as comparatively sure guides to racial origin. Knowing what we now do of segregation and recombination we suspect that no characteristic is incapable of segregation and so of transference to another race: given the possibility of cross-breeding, the shape of the skull or other bodily peculiarity may be transferred in its entirety to individuals descending by another parent from a different race, and hence to a resulting population, more slowly but not less completely than a language or a custom.

The classificatory dichotomies in common use in the systematic arrangement of animals and plants have no prerogative significance except for mnemonic or demonstrative purposes; for the number of the dichotomies is merely an enumeration of the pairs of factorial differences, and the order in which they are taken into account, though often treated as a matter of cardinal importance, is purely arbitrary. Peas, for instance, are divided first into tall varieties and dwarf varieties, then into round and wrinkled, yellow and green, etc., but it would be logically as sound and physiologically as justifiable to divide them first into yellow and green, then into early and late, and so on. If the races of men could be crossed under experimental conditions we should find the same principles governing their distinctions.

(10) *Applications.*—The applicability of genetic discoveries to the betterment of the human race is discussed in the article EUGENICS, but a few words as to the progress in the art of breeding animals and plants made possible by the development of Mendelism may be given here. The use and consequences of crossing in the search for new forms of economic value are now apparent. The reasons for preserving the first generation ($F_1$) though it may present no valuable feature and the desirability of raising from it as many individuals ($F_2$) as space will accommodate, are obvious. The breeder now knows what he is about and is able to interpret countless phenomena previously meaningless. Granting that the chief breeds of animals now in the keeping of civilized man are not capable of much amelioration, experience has shown that enormous improvements can be made by applying accurate knowledge to the breeding of even such old-established crops as wheat, oats, tobacco, etc. If this is true of the crops which have for ages been the object of unremitting care, it will be understood that the cultivated plants of tropical regions offer limitless possibilities. The breeding of coconut, rubber, jute, cacao and many more has scarcely begun. These are all still raised from seed gathered almost promiscuously, the result of uncontrolled fertilization, and the produce is what we should see if our orchards were raised from seeds and those seeds gathered at random from garden varieties and from wildings in the hedgerows. At first, selection and fertilization under control will suffice to make great progress. Even at that stage some genetic knowledge will be of value, but when the more difficult task of making genetic recombinations of desirable qualities is begun the breeder will require skill in the management and interpretation of the generations and the various terms in the series of forms which only accurate knowledge of principle can supply. Genetic science shows primarily what can be expected, providing the breeder with an aim, and also indicates how it may be attained. For example, a crop of sugar beet often contains 4%—sometimes many more—of plants which "bolt" or flower in the first year making no "bulb," and so worthless. This state of things has long been accepted as inevitable. But when the geneticist finds that the annual habit is a recessive, he suspects that the plants which produce the bolters are heterozygous in that respect, and that if he can raise plants homozygous in the biennial habit he will have eliminated bolting. The breeder, whether scientific or practical, ignorant of genetics, would never suspect the nature of the fault, still less could he devise a cure. Common sense in the art of seed-raising is an imperfect guide. Apart from any question of making new races, the purification of existing varieties and their maintenance in a state of purity are exacting tasks. What has been done in these several phases of the industry, in ignorance of principle, is remarkable, but we may confidently foresee that the application of scientific method will in the case of the breeder's art effect a change in magnitude no less than that which has been witnessed in the other industries.

**MENÉNDEZ Y PELAYO, MARCELINO** (1856–1912), Spanish scholar and critic (*see* 18.128), was at the time of his death working at the second edition of his *Historia de los heterodoxos españoles*. He died at Santander May 19 1912, and bequeathed his valuable library of 40,000 volumes to that town.

See A. Donoso, *Menéndez y Pelayo y su Obra* (1913); Bonilla y San Martín, *Menéndez y Pelayo, 1856–1912* (1914); and A. G. de Amezua y Mayo, *Nota bibliografica de Menéndez y Pelayo* (1918).

**MENSDORFF-POUILLY-DIETRICHSTEIN, ALBERT,** COUNT VON (1861– ), Austro-Hungarian diplomatist, was born at Lemberg Sept. 5 1861. He was the second son of Alexander von Mensdorff-Pouilly, Prince Dietrichstein von Nicolsburg, and Alexandrine, born Countess Dietrichstein-Proskau and Leslie. Entering the diplomatic service at an early age, he was assigned in 1886 to the Paris embassy and in 1889 transferred to London, where with short intervals he was ambassador from 1904 to Aug. 13 1914. He used his family relations with the English court, derived through the marriage of Count Emmanuel Mensdorff-Pouilly (1777–1862) with Queen Victoria's aunt, Princess Sophia of Saxe-Coburg, his friendship with Edward VII. and George V., and his popularity in English aristocratic circles, to establish and secure friendly relations between the Cabinets of Vienna and London. In the critical negotiations before the outbreak of the World War he supported every attempt to avert the danger. During the war he was repeatedly entrusted with missions directed towards the restoration of peace. He met Gen. Smuts in Switzerland in Dec. 1917, but these negotiations proved as fruitless as those which he conducted with the Entente representatives in the last days of the Habsburg Monarchy. At the end of 1920 he represented the Austrian Republic on the occasion of its reception into the League of Nations.

**MERCIÉ, MARIUS JEAN ANTONIN** (1845–1916), French sculptor and painter (*see* 18.152), died in Paris Sept. 12 1916.

**MERCIER, DÉSIRÉ** (1851– ), Cardinal Archbishop of Malines, Belgium, was born Nov. 21 1851 at Broine l'Allemt, in the Walloon portion of Brabant, of a bourgeois family. After finishing his course at the college of St. Rombaut at Malines, he entered the larger seminary of that town, and on April 5 1874 was ordained priest. He continued his theological studies at Louvain, and in 1877 was appointed professor of philosophy at the lesser seminary of Malines. In 1882 he was appointed to the recently created chair of Thomist philosophy at Louvain, and during the ensuing years was active in the scheme for founding the Institut Supérieur de Philosophie at Louvain, which was finally opened in 1894.

In Feb. 1906 Monsignor Mercier was appointed Archbishop of Malines in succession to Archbishop Goossens, and in 1907 he was created a cardinal. Soon after the outbreak of war in 1914 he was summoned to Rome to attend the funeral of Pope Pius X. and the election of his successor, and it was therefore not until his return to Belgium that he became fully aware of the incidents

of the German invasion. He personally inquired into many of the allegations against the invading army, and as a result issued his famous pastoral letter "Patriotism and Endurance." In this he strongly protested against the cruelties which had been inflicted on the Belgian population, at the same time recommending submission to the authorities in everything that was just. This pastoral was widely read, in spite of all the efforts of the German authorities, and the cardinal declined in any way to retract his words. Henceforth, during the four years of the German occupation, he did not cease to protest against violations of right and justice by the Germans, and was often in conflict with the military authorities, as his correspondence with the German governor shows. Some of his protests were successful and on Oct. 17 1918 Baron von der Lancken, head of the political department at Brussels, announced to him the impending liberation of political prisoners. The dignity and courage of the cardinal's conduct were universally recognized.

Cardinal Mercier's published works include *Cours de philosophie* (in four vols., I. *Logique*, II. *Métaphysique générale*, III. *Psychologie*, IV. *Critériologie générale*, 1892) and also *A mes séminaristes* (1907); *La Vie intérieure (1918)*; *Retraite pastorale* and five vols. of *Œuvres pastorales*. See also *Correspondance de S.E. le Cardinal Mercier avec le gouvernant général allemand pendant l'occupation.* (F. M.)

**MERRIMAN, JOHN XAVIER** (1841– ), South African statesman, was born on March 15 1841 at Street, Som., England. He was a son of Nathaniel James Merriman (1810–82) who in 1841 had become vicar of Street, and was afterwards archdeacon of Grahamstown, dean of Cape Town and, from 1871, Bishop of Grahamstown. The family removed to South Africa in 1849. John Xavier was educated at the Diocesan College, Rondesbosch, and later at Radley College, England. He returned to South Africa in 1861 and became a farmer.

Merriman began his political career in 1869, when Cape Colony was in the transition stage of representative government. In temperament and outlook an aristocrat of the Whig school his subtle mind brought him in turn into coöperation with opposing parties, but he was always a champion of personal liberty and an advocate of native rights. In 1872, despite his opposition, the Cape obtained self-government, and in 1875 Merriman joined the Molteno Ministry as commissioner of public works. He was already distinguished for his energy and capacity, and when in 1877 war with the Galeka Kaffirs broke out Merriman became virtually Secretary for War in the Cabinet. In this work he came into collision with the governor, Sir Bartle Frere, who complained of Merriman's "insane attempt to ape Gambetta," and insisted that he (Frere) alone had the right to direct the war. Molteno supported Merriman; in the result Frere dismissed the Cabinet, Feb. 1878.

Merriman came into office again in the Scanlen Ministry (1881–4), and again as commissioner of public works. It was a period of great difficulty following the Majuba campaign and the retrocession of the Transvaal. In the Cape the Afrikander Bond had been formed, and its more than dubious attitude to the British connexion alienated Merriman from the Dutch extremists. "My quarrel with the Bond," he said in a speech at Grahamstown in 1885, "is that it stirs up race differences. Its main object is to make the South African Republic (the Transvaal) the paramount power in South Africa." The Bond had caused the fall of the Scanlen administration because the Ministry opposed the attempt of the Transvaal Boers to seize Bechuanaland. In the last few weeks of its existence Merriman and Cecil Rhodes had been colleagues and when Rhodes formed a Ministry in 1890 Merriman joined it as treasurer-general. Meanwhile the Bond, under the guidance of Jan Hofmeyr, had adopted a constitutional programme, and 1890 saw a drawing-together of the Dutch and British elements at the Cape. But the uitlander troubles in the Transvaal became acute, and in 1893 Merriman resigned. In Dec. 1895 came the Jameson Raid. Merriman, who was chairman of the Cape parliamentary committee which inquired into the raid, and drew up its report, desired reforms in the Transvaal, not its absorption into the British Empire. "The greatest danger to the future," he declared in a letter to President Steyn (dated March 11 1898), "lies in the attitude of President Kruger and his vain hope of building up a State on a narrow, unenlightened minority."

The general election in Cape Colony in the latter half of 1898 gave the Bond a very narrow victory, and P. W. Schreiner became Prime Minister, with Merriman (treasurer-general again) and J. W. Sauer as his chief colleagues, though none of them was members of the Bond. This was the Ministry in office when the Anglo-Boer War of 1899–1902 broke out (*see* 5.244). Merriman was among the ministers who in 1900 opposed the measure to disfranchise the Cape rebels; this opposition led Schreiner to tender the resignation of the Cabinet. Later Merriman and Sauer came to England to plead for the restoration of the independence of the Boer republics. At the general election of 1904 Merriman was defeated, but was returned shortly afterwards at a by-election. He led the opposition during the Ministry of Dr. Jameson and in Jan. 1908 succeeded him as Prime Minister and treasurer-general (*see* 5.247).

Merriman lent the weight of his great authority to the movement for unification and was a member of the national convention which hammered out the new constitution. He was one of the delegates who came to London in connexion with the passing of the South Africa Act as well as a delegate to the imperial conference on naval and military defence of 1909, on which occasion he was made privy councillor. When on the establishment of the Union in 1910 the Cape Parliament ceased to exist he did not join the Union Ministry under Botha (*see* article SOUTH AFRICA, section *History*). He remained a somewhat detached member of the South African party and a not infrequent critic of ministers. Holding that as an equal member of the British commonwealth South Africa had found its proper place, he opposed the disruptive policy of Hertzog as strongly as he had formerly supported the independence of the Boer republics. He married, in 1874, Agnes, daughter of Mr. L. Vintcent, a member of the Cape Legislative Council. (F. R. C.)

**MERRITT, WESLEY** (1836–1910), American soldier (*see* 18.173), died at Natural Bridge, Va., Dec. 3 1910.

**MERRY, WILLIAM WALTER** (1835–1918), English classical scholar, was born at Evesham Sept. 6 1835. Educated at Cheltenham and Balliol College, Oxford, he became fellow and lecturer of Lincoln College, Oxford, in 1859 and rector of the college in 1884. A witty and fluent speaker both in Latin and in English, he acquired a great reputation as public orator to the university, a post he held from 1880 down to the time of his death. He published editions of many of the plays of Aristophanes (1879–1900), as well as an edition of Homer's *Odyssey* (1870–8) and *Selected Fragments of Roman Poetry* (1891). He died at Oxford March 5 1918.

**MERSEY, JOHN CHARLES BIGHAM, 1ST VISCOUNT** (1840– ), English judge, was born at Liverpool, Aug. 3 1840, and was educated at the Liverpool Institute and later at Berlin and Paris. He was called to the bar in 1870, was made a Q.C. in 1883, and became leader of the northern circuit. He entered the House of Commons in 1895 as Unionist member for the Exchange division of Liverpool, but lost his seat in 1897. In the same year he was raised to the bench and knighted. In 1902 he was president of the Royal Commission for the revision of the South African martial law sentences, and from 1904 to 1908 president of the railway and canal commission. From 1904 to 1910 he was chief judge in bankruptcy, and in 1909 became president of the Probate, Divorce and Admiralty division of the High Court, and was made a privy councillor. In 1910 he was raised to the peerage. He was recognized as one of the highest authorities on Admiralty and shipping questions, and in 1912 became wreck commissioner, being the same year president of the commission which investigated the loss of the "Titanic." He presided in 1913 over the conference on the safety of life at sea, and in 1914 over the commission of inquiry into the loss of the "Empress of Ireland." On the outbreak of the World War Lord Mersey's wide experience and knowledge were recognized by his appointment as head of the Admiralty transport arbitration board, and in 1915 he investigated the circumstances

attending the losses of the "Falaba" and the "Lusitania." In 1916 he was created a viscount.

**MERTHYR, WILLIAM THOMAS LEWIS, 1ST BARON** (1837–1914), British engineer, was born at Merthyr-Tydvil Aug. 5 1837. He was trained as a civil engineer and in 1864 married Anne Rees, daughter of a S. Wales coal-owner. Thenceforth he was a large employer of labour in the S. Wales collieries and effected many improvements both in the machinery of the mines and the condition of the miners. He was the originator of the sliding scale of wages introduced into the district in 1875, and also of a miners' provident fund. He was called in to settle the serious Taff Vale railway strike in 1900, and was an active worker for industrial peace. He was a member of several Royal Commissions, was knighted in 1885, created a baronet in 1896 and raised to the peerage in 1911. He was made K.C.V.O. in 1907 and G.C.V.O. in 1912. He died at Newbury, Berks., Aug. 27 1914.

**MESDAG, HENDRIK WILLEM** (1831–1915), Dutch marine painter, was born at Groningen Feb. 23 1831. He adopted a business career, entering the family banking firm of Mesdag, but about 1866 he came under the influence of Josef Israels, with the result that he took up the study of art. His sea pieces became famous, and earned him the gold medal of the Paris Salon, among them being "Effet du soir à Scheveningen" (1872); "Après l'Orage" (1895); "Rentrée des bateaux de pêche" (1900) and "Une soirée sur la plage de Scheveningen" (1911). He also made a fine collection of pictures and *objets d'art*, which he presented to the nation, and they are housed in the Mesdag museum at The Hague. He died at The Hague July 7 1915.

**MESOPOTAMIA** (*see* 18.179).—In the classical sense "Mesopotamia" is the country from Mosul and Tikrit on the Tigris to the borders of Syria. In the earlier article it was this area which was described under the heading of MESOPOTAMIA. It was then said concerning the name itself that "in modern times it is often used for the whole Euphrates country. That would provide a useful name for an important geographical unit, but it is too misleading." The point has, however, now been settled, for when the Indian Expeditionary Force landed at the head of the Persian Gulf in 1914 the public decided that it was Mesopotamia which was in question, and the name is now applied, under the sanction of international treaties, to the country stretching from the head of the Persian Gulf as far up the Tigris and the Euphrates as the direct responsibilities of the British Government extend. The area coincides, except for a slight variation in the northern boundary, with the Turkish vilayets of Basra, Bagdad and Mosul. The Arab name for what is now called Mesopotamia is *Iraq*—a term (sometimes Englished as Irak) formerly covering only the alluvial plain from about Tikrit southwards, but now commonly and even officially used for the whole area governed from Bagdad.

The boundaries of Mesopotamia are: N., a line running roughly E. and W. through a point on the Tigris rather nearer to Jeziret ibn 'Umar than to Mosul. S., territory of the Sheikh of Mohammerah (Persia), the Persian Gulf and Kuwait. E., the Turco-Persian frontier (this boundary was the subject of a Turco-Persian commission assisted by British and Russian representatives in 1913–14; the commission completed its labours just before the war began, but its report was never ratified). W., the Arabian and Syrian deserts.

Southern Mesopotamia consists of an alluvial plain which stretches from the Persian Gulf a distance of some 400 m. to the north. This plain passes into rolling downs S. of Mosul; and beyond Mosul, to the N. and E., it rises into the limestone mountains of Kurdistan, where some peaks attain a height of 11,000 feet.

*Climate.*—The climate of Mesopotamia is continental sub-tropical. The main features are large daily and annual ranges of temperature, lack of moisture and scanty rainfall. The annual rainfall totals recorded at the three largest towns are:—

| Place | Number of years | Annual average rainfall in inches |
|---|---|---|
| Basra | 18 | 6·68 |
| Bagdad | 29 | 6·64 |
| Mosul | 4 | 16·71 |

All the rain falls during the winter months; there is a long rainless summer lasting from April or May to Oct. or November. The temperature in summer is as high as that of any place in the world; 120° F. in the shade is not uncommon at Bagdad and Basra and in 1921 128° F. in the shade was recorded at Basra. On the other hand severe frost is often experienced in winter. At Mosul temperatures of over 30° F. below freezing-point have been registered, and the absolute minimum on record runs from 0° F. at Mosul to 19° F. at Bagdad and 24° F. at Basra. The heat of summer is tempered by the excessive dryness of the atmosphere and by the prevailing wind, the *shamal*, which blows from the north. (A. T. W.)

*Medical Conditions.*—The Tigris and Euphrates and the Shatt al Arab river formed by their junction overflow their banks in the spring and early summer months owing to the water derived from the melting snows of the mountains near their source. As a result of this, the lower portions of Mesopotamia contain large marshy districts near the banks of these great rivers which have a great influence on the hygienic conditions prevailing. The hot months of the year are from May to Oct., the hottest being July and Aug., but fortunately even in these months the nights are relatively cool. Just as in the case of the Persian Gulf, the intense heat is rendered much more dangerous to human life by the high relative humidity of the atmosphere caused by the moisture derived from the rivers and marshy districts adjoining.

The dangers from heat exposure experienced in the Persian Gulf exist equally in the lower parts of Mesopotamia, such as Basra, Mohammerah, Gurna and as far up the Tigris as Ezra's Tomb, and similarly the lower reaches of the Euphrates up to Nasiriya are subject to like climatic conditions. In these districts, owing to the ample opportunities provided by the marshy areas, mosquitoes flourish abundantly and the malaria-carrying *anopheles* varieties are prevalent. Malaria is consequently a disease which is very common, and it is usually of the type known as benign tertian. In these regions the greatest care is necessary to avoid infection and the constant use of mosquito-nets is essential. The taking of quinine, 5 gr. *per diem*, has been recommended as a prophylactic measure during the months when mosquitoes abound, but the mosquito-net is the surer safeguard. The other parts of Mesopotamia are subject to equally high temperatures but the air is drier and the dangers from heat-stroke are much less. Malaria is less prevalent, though it occurs in the neighbourhood of the marshy districts.

Dysentery is prevalent throughout Mesopotamia. The form of dysentery caused by the *Amoeba dysenteriæ* occurs all the year round and it may be complicated by inflammation of the liver and liver abscess. The other variety of dysentery known as bacillary dysentery is common and is apt to occur in epidemic form, especially in the autumn months. Both varieties of dysentery are conveyed by impure water, so that the drinking of water which has not been boiled or chlorinated, or the eating of salads, etc., which may have been washed in contaminated water, must be carefully avoided.

Enteric fever, which includes typhoid fever and the fevers of paratyphoid A and B organisms, is a water-borne disease and is common in Mesopotamia. A valuable protection against them is afforded by prophylactic inoculation with T.A.B. vaccine, which protects against the three enteric-group fevers. Every resident should obtain the valuable protection afforded by a yearly inoculation with T.A.B. vaccine.

Cholera occurs in Mesopotamia and is a water-borne disease. It is frequently also introduced into Basra by infected persons arriving on ships from India and elsewhere. Prophylactic inoculation against cholera has been recommended, but the immunity conferred is of short duration, only lasting a few months, and it is not recommended as a protection for white residents unless a serious epidemic is prevalent.

"Carriers" of disease are persons who are apparently in good health but whose excreta contain the organisms of an infectious disease. "Carriers" of the water-borne diseases above mentioned, dysentery, enteric-group disease and cholera, are frequently found in tropical countries; and not uncommonly cooks and servants or persons who handle food and drink, when "carriers" of these diseases, cause infection to others. Such persons suspected of being "carriers" of disease should be submitted to a bacteriological examination which would detect the presence of the disease-producing organisms in their excreta.

Sand-fly fever is exceedingly common; it is an acute and painful fever of about three days' duration which is caused by the bite of an infected sand-fly (*Phlebotomus Papatasii*). This pest is so small that it can readily find its way through an ordinary mosquito-net, and in order to protect oneself against sand-fly fever it is necessary to sleep under a net of sufficiently fine mesh to prevent its entry. Sand-fly nets are commonly used in the tropics and are preferable to ordinary mosquito-nets, since they keep out both sand-flies and mosquitoes. Insect repellants, such as oil of citronella, eucalyptus, paraffin, vermijelli, turpentine, etc., may be smeared on exposed parts of the body to prevent the bites of sand-flies and mosquitoes at times when one is not protected by a net.

Plague is not common in Mesopotamia, though in former years serious epidemics have been recorded. At the present day plague is generally introduced from India by cargoes landed in the Mesopotamian ports, and sporadic cases frequently occur in Basra amongst seafaring people. The disease is spread by rats, which are readily infected with the *Bacillus pestis*, the organism being carried from the rat to man by the flea. Prophylactic inoculation is of value

when an epidemic is prevalent, and in 1919 it was a valuable means of arresting an epidemic of plague amongst the native populations of Basra, 'Amara and Bagdad.

Oriental sore (Bagdad boil) is very common in Mesopotamia, and few of the native population escape infection. It is a chronic ulcer caused by inoculation of a protozoal organism known as *Leishmania tropica* by means of an insect bite, probably the sand-fly. The latent period may be several months. It is a slowly healing sore, lasting often a year or more, and leaves a scar. Usually exposed parts of the body are affected and the scars are known as date-marks.

Eye diseases such as conjunctivitis, trachoma, etc., are exceedingly common amongst the natives of Mesopotamia and cause a great amount of blindness. They are spread by dust, dirt, flies and infection from one person to another. There is an immense field of much-needed work open to specialists in eye diseases in Mesopotamia, since most of these are preventable and many curable.

Tuberculosis in all its forms is a fairly common disease amongst the native population. Leprosy is also fairly common and no attempts have been made in the past to isolate affected persons. Smallpox is of frequent occurrence and every resident should be protected by repeated vaccination. Typhus fever is also of frequent occurrence in Bagdad and the northern areas of Mesopotamia. It is a disease carried by infected lice, and is introduced into the country annually by lice-infected persons along the caravan routes from the cooler countries adjoining, viz. Persia and Asia Minor. Typhus is of rare occurrence in the southern parts of Mesopotamia, the intense heat destroying lice. Venereal diseases, such as syphilis and gonorrhoea, are common amongst the native population.

Diarrhoeal diseases are very common, and are due to infection of food and drink by dust, flies, and contaminated water. The Arab children are severely affected, and infantile mortality is high.

Deficiency diseases, such as scurvy and beri-beri, were prevalent to a great extent during the early part of the World War amongst the British troops in Mesopotamia. This was due to the difficulty of transport of fresh vegetables and fruit on account of their perishability owing to the intense heat. These diseases are not likely to occur during peace conditions and they do not appear to occur amongst the native population, who can obtain fresh and wholesome food, dates, vegetables, corn and meat, etc., in abundance.

Though this account of the diseases occurring in Mesopotamia may appear somewhat alarming to those contemplating residence there, nearly all of the diseases are preventable by simple precautions, such as care of food and drink, protection at night from insect bites, avoidance of unnecessary exposure to heat, and the ordinary habits of personal cleanliness. Under proper precautions Mesopotamia is a healthy country, especially north of 'Amara and Nasiriya, and for 8 months in the year the climate is perfect. There is no reason why white races resident there should not experience excellent health, but it is advisable that residence in a cool climate during July and Aug. should be arranged for as often as possible.

(W. H. W.)

*Population.*—According to a census taken in 1920 the pop. of Mesopotamia is nearly three millions. The figures, according to religions, are given in Table 1.

The population is Arab, with the following exceptions: (1) A strong Turkish element in a string of towns stretching N. from Mandali near the Persian border, through Kifri and Kirkuk to Altun Köprü and Erbil. Tall Afar, some 40 m. W. of Mosul, is a Turkish town, and there are Turkish villages in the plain of Mosul. These Turks are not Osmanlis but descendants of earlier Turkish invasions and of mercenaries brought in by the Abbasid caliphs to guard the borders of their realm. (2) The Kurds, who inhabit, to the almost complete exclusion of other races, the country E. of the line of Turkish towns. (3) The Jews, most of whom live in Bagdad, Basra and Mosul. They are supposed to be descended from those Jews of the Babylonian captivity who disregarded Nehemiah's summons to return to rebuild the walls of Jerusalem. (4) The Christians, who are confined to the big towns, except in the Mosul area where there are several thriving Christian villages which live by agriculture. Most of the Christian population are Chaldeans (*i.e.* Nestorians who have become Roman Catholics), but there are some Syrian Catholics and a few Jacobites (or old Syrians) and Armenians; and during the war thousands of Nestorians drifted to Mesopotamia as refugees from the country between Lake Van and Lake Urumia, and some of these have settled in villages to the N.E. and E. of Mosul. (5) A considerable Persian population living in the Shiah towns of Najaf (Nejef), Karbala and Kadhimain, and in Bagdad. (6) The Yezidis (the so-called devil-worshippers), who inhabit the Sinjar and also certain villages E. of Mosul. (7) The Sabeans (Mendaites), a curious people, now reduced to a handful, who live in Lower Mesopotamia, mainly at Qal at Salih and Suq ash Shuyukh. They hold John the Baptist in great reverence and there are traces of star-worship in their cult.

The Arabs, who by reason of their numerical predominance give the character to the country, range from the partly Europeanized "notables" of Bagdad to the almost Bedouin population of desert "ports" such as Zobeir and Kubaisa; from sections of ancient tribes, famous in pre-Mahommedan verse, such as Bani Tamin and Khasraj, to the wild "Marsh Arabs" of Lower Mesopotamia, who are hardly recognized as Arabs by the rest of the population; from sheep-rearing tribes, nomad or semi-nomad, to men who have cultivated the same date-gardens for generations and have long lost all their tribal characteristics.

*Religion.*—Except for the insignificant proportion which is composed of Jews, Christians, Yezidis and Sabeans, the people of Mesopotamia are all Mahommedans. They are, however, split into Shiahs and Sunnis. South of a line drawn roughly from W. to E. through Bagdad, the population, except for the big towns, is almost exclusively Shiah (Shi'ah) while N. of it few Shiahs are found. All the Turks, and with very few exceptions all the Kurds, are Sunnis.

*Language.*—The Turks of the Erbil–Kirkuk–Mandali line talk a tongue that is akin to Azerbaijani rather than to Ottoman Turkish. The Kurds and the Yezidis talk Kurdish, which is closely allied to Persian and, indeed, is maintained by some to be only a Persian dialect. It may be said, however, that south and west of the Turkish towns only Arabic is spoken. There are considerable variations in vocabulary and pronunciation. Everywhere there is found an admixture of Turkish, Persian and—in the south—English words, but the Arabic of Mesopotamia is generally pure and homogeneous.

*Agriculture.*—The most important occupation is agriculture. The winter crops are wheat and barley, barley predominant in the Bagdad and Basra areas, wheat in the Mosul area. In the north the winter crops are grown on the rain; but in the south, where the rainfall is less than seven inches, no crops are grown (except, occasionally, scanty catch crops) without assistance from irrigation. For summer crops, even in the north, irrigation is required. The chief summer crop is rice, which is grown chiefly in the marsh lands of the middle and lower reaches of the Tigris and the Euphrates. Most of this rice is red rice of common quality. Better kinds, but in very small quantities, are grown in the Kurdish hills. Millet also is grown, and a little maize. In the Kurdish hills large quantities of cigarette tobacco are produced, and the coarse tobacco used for water-pipes (*tumbak*) is grown on a small scale in the Hilla area. Before the war cotton was grown in very small quantities for local use. The silk industry had been started, but on a small scale.

A very important product is the date. It is grown mainly in the tidal stretches of the Shatt al 'Arab. From Fao to Qurna, a distance of about a hundred miles, there is an almost continuous grove

TABLE 1.—*Population.*

| Division | Sunni | Shiah | Jewish | Christian | Other Religions | Total |
|---|---|---|---|---|---|---|
| Bagdad | 130,000 | 54,000 | 50,000 | 15,000 | 1,000 | 250,000 |
| Samarra | 66,455 | 14,215 | 300 | — | — | 80,970 |
| Diyala | 54,953 | 46,097 | 1,689 | 397 | 900 | 104,036 |
| Kut | 8,578 | 98,712 | 381 | 127 | — | 107,798 |
| Diwaniya | 1,000 | 192,300 | 6,000 | 5,000 | 200 | 204,500 |
| Shamiya | 445 | 189,000 | 530 | 20 | 5 | 190,000 |
| Hilla | 15,983 | 155,897 | 1,065 | 27 | 28 | 173,000 |
| Dulaim | 247,000 | 200 | 2,600 | 200 | — | 250,000 |
| Total vilayet of Bagdad | 524,414 | 750,421 | 62,565 | 20,771 | 2,133 | 1,360,304 |
| Basra | 24,408 | 130,494 | 6,928 | 2,221 | 1,549 | 165,600 |
| 'Amara | 7,000 | 284,700 | 3,000 | 300 | 5,000 | 300,000 |
| Muntafiq | 11,150 | 306,220 | 160 | 30 | 2,440 | 320,000 |
| Total vilayet of Basra | 42,558 | 721,414 | 10,088 | 2,551 | 8,989 | 785,600 |
| Mosul | 244,713 | 17,180 | 7,635 | 50,670 | 30,180 | 350,378 |
| Erbil | 96,100 | — | 4,800 | 4,100 | 1,000 | 106,000 |
| Kirkuk | 85,000 | 5,000 | 1,400 | 600 | — | 92,000 |
| Sulaimani | 153,900 | — | 1,000 | 100 | — | 155,000 |
| | 579,713 | 22,180 | 14,835 | 55,470 | 31,180 | 703,378 |
| Grand Total | 1,146,685 | 1,494,015 | 87,488 | 78,792 | 42,302 | 2,849,282 |

of date-palms on each side of the river. But every town as far north as Samarra on the Tigris and 'Ana on the Euphrates has its date-groves. Large flocks of sheep are raised, particularly in the Mosul and Kurdistan areas; their wool and skins are important articles of export.

*Industries.*—The industries of the country—dyeing, tanning, leather-working, silk-spinning and weaving—are for the local market only. The large towns, especially Bagdad, live on the distributing trade of Mesopotamia and Persia. On account of the competition of the Caucasus routes Bagdad was declining in importance during the decade before the World War.

### Political History, 1910–21

The Constantinople revolution of 1908 brought to Mesopotamia as to other parts of the Turkish Empire such advantages as freedom to travel, but the population outside the big towns was scarcely affected. The strong centralizing influence of the Committee of Union and Progress was represented by branches in the large towns, and the decentralization (Adem-i-Merkeziyet) party seems to have had little open support, though the tribal Arab continued to resist centralization as represented by attempts to collect taxes, and in Basra a local notable, Saiyid Talib, was able to raise himself to a position of influence from which no efforts of the Turkish Government could oust him. In the matter of education Syria was half a century ahead and that perhaps accounts for the greater strength of the Arab movement in Syria. Even in the use of their mother tongue the inhabitants of Mesopotamia seem to have been lukewarm, and the concession regarding the teaching of Arabic and its use in official documents, wrung from the Turks mainly by disturbances in the Yemen, was little appreciated if indeed adopted in Mesopotamia. The most important posts, *e.g.* the governorships of Bagdad and Mosul, continued to be filled by Turks, and such posts of influence as were given to Mesopotamians went, with very few exceptions, to the local Turks of Kirkuk, Erbil, etc. Attempts to encourage education were, however, made, and the largest school in Bagdad owes its construction to a subscription—not perhaps always voluntary—raised by the Committee of Union and Progress. The "Young Turks" also paid some attention to the possibility of developing Mesopotamia. They engaged the distinguished engineer Sir William Willcocks to draw up an irrigation scheme for the country and, by acting on his report to the extent of getting a British firm to build the Hindiya Barrage, whereby the Euphrates could at will be turned down the left arm of the river, past Hilla and Diwaniya, they restored to prosperity an area which had fallen into destitution and been largely depopulated. The claim that this policy was due to real foresight on the part of the "Young Turks" is discounted to some extent by the manner in which they treated the Crown lands which had formerly belonged to Sultan 'Abdul Hamid and had been confiscated when he was deposed. 'Abdul Hamid had been a model landlord to the cultivators of these estates, giving advances of seed on easy terms and granting remissions of revenue in bad years; but the Turkish Government concerned itself with nothing but squeezing out the maximum revenue, and the estates had deteriorated considerably by the time the war began. One real concession, however, was made to provincial opinion in Turkey, and Mesopotamia profited by this. Certain minor heads of revenue were allocated to objects of public utility, *e.g.* education and medical work, in each province and the control of the expenditure was given to the provincial council.

Law and order were no better, though perhaps no worse, than in 'Abdul Hamid's time. Nearly every summer, when the crops had been harvested, there was trouble somewhere. Travel on the Hai and the Euphrates was often unsafe; there were several serious acts of piracy on the Shatt al 'Arab at Basra; the inhabitants of Diwaniya cut off the head of their governor; and in the spring of 1914 Turkish forces were defeated in a pitched battle at Shatra and lost guns and many men.

An important and disagreeable feature of the period was the anti-British attitude of the Turkish authorities in Mesopotamia. Partly as a result of a quite legitimate desire to throw off all foreign control, as represented especially by the judicial and other privileges of foreigners (usually known as the "Capitulations"), and partly as a consequence of an inflated conceit, the "Young Turk" was inclined to be hostile to foreigners in Turkey, and in Mesopotamia there were few other foreigners to share this hostility with the British. Her long connexion with the Persian Gulf, the proximity of Basra to India, the importance attached by the Indian Government to Mesopotamia as a market and as the goal of thousands of Indian pilgrims, and the importance of British trade in the country, combined to give Great Britain a predominant position in Mesopotamia, and that predominance was emphasized by certain privileges consecrated by concession or custom, notably the right of the British Consulate-General at Bagdad to have a sepoy guard at the consulate and an armed Royal Indian Marine ship in the river, and the right of Messrs. Lynch to run boats on the Tigris and to fly the British flag on them. There is no doubt that the hostility of the Turks was fostered by the Germans, who had begun to build a section of the Bagdad railway northwards from Bagdad and had started several German firms in Mesopotamia. Meanwhile British interests were increasing in importance, owing to the relations with the neighbouring sheikhs of Kuwait and Mohammerah, to the growth of the oil interests just over the Persian border, and to the now urgent necessity of ensuring that no European Power should establish itself at the head of the Persian Gulf. Negotiations which had for their object the settlement of all outstanding questions in Mesopotamia were in progress when the World War broke out. It is said that, under an agreement which had been initialed but not ratified, the British Government were to participate in the last section—Bagdad to Basra—of the Bagdad railway, and were to have a controlling interest in the port of Basra.

The outbreak of the World War, however, in Aug. 1914 put an end to this. It speedily became evident that the attitude of Turkey towards the Allies would at best be that of malevolent neutrality, and in Mesopotamia this attitude was particularly marked. Before the end of Aug. the Basra authorities were making badly concealed preparations for blocking the Shatt al 'Arab, with the result that only two British vessels ventured up to Basra during the next two months, and those at the masters' own risk and peril. In defiance of ancient treaties the Turks, believing that Europe was too busy to resent any affront, however gross, issued decrees declaring that as from Oct. 1 1914 the Capitulations would cease to be recognized, the foreign post-offices in Turkey would be closed, and the customs dues would be raised from 11% to 15% *ad valorem*. The predominance of British over all other foreign interests in Basra and Bagdad made it seem to the local population as though these measures were directed almost exclusively against England, and anti-British feeling was created and fostered by the dissemination of propaganda derived mainly from German sources. Not content with action within their own borders, the Turks threatened the sheikh of Mohammerah and the independent sheikh of Kuwait with hostile action unless they adopted a policy of active coöperation with the Turks.

With the outbreak of war consequent on the Turkish bombardment of Odessa the Turkish officials' policy of pin-pricks changed to active hostility. British and British-Indian subjects were arrested and British goods of all kinds seized; and at the British Consulate-General at Bagdad the floors of the cellars were pulled up in a vain search for the stores of arms and ammunition and the hoards of gold which were supposed to be hidden there to be used in a British attempt to seize Mesopotamia.

The hostile attitude of the Turkish Government, their threats to the friends of Great Britain in the Persian Gulf, and the menace to the oil industry in Persia had already compelled the British Government to take precautionary measures. In Oct. a force of all arms was sent from India to Bahrein to await developments. When the Turks forced war on the Allies by attacking Russia, this force moved up the Gulf and occupied Fao and, after some resistance, Basra. The military campaign, from the occupation of Basra with one division till the time of the Armistice, when British and Indian troops—the advance-guard of a great host—were at Mosul, threw a great strain

on British resources, and on the personal courage and endurance of the men employed. There were no battles on the scale of those in France; but the qualities of the British and Indian troops in Europe can be matched by those shown by their comrades in arms in Mesopotamia in such operations as the capture of Nasiriya in the middle of the hot weather, in the defence of Kut, in the gallant attempts to relieve Kut, and in the stoical endurance by British and Indian prisoners of the calculated barbarities of the prisoner-of-war camps.

Whether to attack the Turks in Mesopotamia was wise or not has been the subject of much discussion. Why the expeditionary force went to Basra is clear enough. The Turks were threatening the friends of Great Britain in the Persian Gulf; and there was good ground for the belief that the supply of oil from the Persian oil fields—essential for the navy—might be cut off by the Turks on some pretext or other. But was there any necessity to go farther than Basra? Was the occupation conducted as part of a carefully thought-out policy, or was it carried out, as the British Empire is said to have been built up, in a fit of absence of mind? It is claimed that the successive advances were forced on the British Government in the first place by military necessity. The battle at Shu'aiba, only 12 m. from the British base at Basra, and the successful raid (instigated by the Turks) on the oil pipe-line in Persia, showed that it was essential to push the Turks farther back. Once Basra and the pipe-line were secured by the capture of 'Amara and Nasiriya, it might have been thought sufficient to consolidate the position; but as often as Turkish armies re-formed it was necessary, according to the military authorities, to go forward and destroy them, and, having destroyed them, the British forces stayed in the area captured.

There were not wanting critics who attributed the campaign in Mesopotamia to a desire to control the oil supplies of the country, but such critics ignore the considerations set forth in the preceding paragraph and the whole history of British relations with the Persian Gulf. Moreover, the oil supplies of Mesopotamia were already in British hands.

It was repeatedly announced, in the course of the campaign, that Great Britain had come to fight the Turk, not the Arab, and on the whole the Arabs (and the non-Arab inhabitants, too, Kurds and even Turks) reciprocated by not fighting against the British. The Turkish authorities in Mesopotamia got little help from the local people. Of those called up for military service many fled, and those who were actually brought into the fighting line fought without heart. Large bodies of Arab and Kurdish tribesmen came down with the Turks early in 1915 to fight at Shu'aiba, but they held aloof during the battle and after the defeat of the Turks they scattered, never to re-form. It is true that the most prominent member of the Sa'dun family, 'Ajaimi, joined the Turks (after negotiating unsuccessfully with the British authorities) and remained their ally until the end of the war, but he never once joined battle with the British forces, or, indeed, did anything else to earn the monthly subsidy the Turks paid him.

But it must not be thought, because they gave the Turks no help, that the Arabs eschewed violence. They hung on the skirts of both armies, and after a battle murdered the wounded and stragglers and robbed living and dead on both sides. The beaten side suffered most, and it was fortunate that it was usually the Turks who were beaten. Nevertheless, once an area was definitely occupied, the country usually became quiet enough. The sheikhs maintained order among their tribes, and native police were formed to help keep the peace in the towns and along the lines of communication.

It is a proof of the strength of the Turkish hold over Mesopotamia that when the Turks withdrew the whole administration collapsed. The mere departure of the Turkish officials was enough to ensure this, for they held nearly all the highest executive positions; but to make doubly sure the Turks sometimes compelled the few Arab officials occupying posts of importance to go with them, and they always, if there was time, carried away or destroyed the official records, in order to embarrass the invader and—it would appear—to spite the Arabs for the lukewarmness of their support.

Thus it happened that the occupying forces found that the whole framework of civil government had fallen to pieces, and the political officers accompanying the troops had no easy task to put it together. The task would have been impossible but for the retention and extension of the system of using tribal sheikhs as—if one may use the expression—sub-contractors in the work of government. The sheikh was made responsible for law and order in his own tribal area, and was often used as the medium for revenue collection. The defect of this system is that it puts wealth and power into the hands of sheikhs who may at any time use them against the Government which has made them—a defect which the Turks remedied by setting one sheikh against another and by various other devices which could not be copied by a British administration. But, good or bad, the system was inevitable during the occupation.

With each successive advance the task of the administration became more difficult, not merely because of the difficulty of finding officials of experience to take over an area constantly growing, but also because, as the war went on, the country in the Turks' hands fell into greater destitution. Thousands of people at Khaniqin were found to have died of starvation; and at Kifri, when the British forces entered the town, starving women and children—the men had nearly all fled to avoid conscription—were eating grass, and the only food in the whole of the bazaar was a few handfuls of dates. For the last eighteen months of the war, almost the first work of a political officer in a newly occupied district was to get food from Bagdad for the civil population. The country, however, showed great vitality: in a few weeks the bazaar would be busy, in a few months more busy than ever.

On the whole the Turkish system of administration was continued with little change. To effect economy the work of collecting the taxes allotted to the Public Debt and the Tobacco Régie was handed over to the Government revenue officials, and the appointment of British officials as heads of districts made it possible to abolish the clumsy division of executive and revenue functions which provided the Turks with a necessary counter-check on corruption. In the sphere of law two concessions were made to local requirements. The first was the official recognition of the impossibility of treating wild tribesmen by the ordinary processes of law, and the introduction of a regulation, adapted from a regulation in force on the Indian Frontier, providing that civil and criminal cases in which a tribesman was concerned might be settled according to tribal custom.

The second was the institution of recognized Shiah Qadhis to deal with questions of personal status, inheritance, etc., among Shiahs, so that Shiahs might not be forced, as they were under the Turkish régime, either to accept the ruling of a Sunni Qadhi, or to settle their difficulties by private arrangements which might afterwards be questioned in a court of law.

Apart from a few changes of which these are perhaps the most important, the British administration rests its claim to superiority over the Turkish mainly on the greater care and honesty shown in working the existing system. The Department of Waqf (Pious Endowments), for instance, was penniless, the mosque employees were paid ludicrously small stipends, and the mosques and religious schools were tumbling into ruin; yet every year considerable sums were remitted to Constantinople, where they were absorbed to a very large extent in overhead charges. Now salaries were raised—in some cases hundreds per cent, a large number of Waqf buildings were repaired, and a substantial balance was built up. Then, whereas the Crown lands were being rapidly bled to death before the occupation, a system of agricultural loans, combined with irrigation works and skilled advice, and applied to private as well as to Government lands, contributed greatly to the prosperity of the country. And so on in each department of Government activity.

The inquiry is naturally made: Why was it, if the British administration studied the interests of the local population more than the Turkish, and the Arabs showed no hostility to the British during the war, that a widespread rising broke out when

the war was over? Some regard the rising as the result of a pure passion for liberty, of an exalted spirit such as led to the liberation of Italy; others consider it a mere ebullition of turbulence such as had swept over Mesopotamia every few years since the Arabs imposed themselves on the Persians in the 7th and 8th centuries. It is worth while setting down the most important of the causes to which the rising was attributed by various authorities.

1. Arab nationalist sentiment. (This is of sufficient importance to be considered separately, below.)

2. The natural turbulence of the Mesopotamian tribes. Many of these tribes—particularly those on the Euphrates—never have submitted to authority for long. They were constantly in revolt against the Turks; and the enforced tranquillity of two or three years under the British peace made the outbreak, when it did come, still more violent.

3. The increase in the number of modern weapons in the hands of the local population. Before the war the Arab of Mesopotamia was lucky if he owned an old Martini; now, as a result of war conditions in the Near and Middle East, nearly every able-bodied man has a Mauser or other magazine-loader, and the temptation to a primitive man to shoot just because he has the means to shoot effectually is very great.

4. The reduction of the British garrison in Mesopotamia. This gave rise to the belief—carefully fostered by interested parties—that the British were leaving the country. The prospect of loot and of hitting an enemy who appeared to be down must have been alluring to the Arab.

5. The talk of "self-determination." This principle, in the form in which it reached minds reared in the rather primitive conditions of tribal Arab life, was often taken to mean the right to throw off all authority, to rob any weaker neighbour of his property or his women folk, to levy tolls on all traffic passing by, and, of course, to refuse payment of taxes.

6. The influence of the Shiah mujtahids. The history of Mesopotamia since the Arab conquest shows clearly that the Shiah towns have constantly rebelled against whatever authority there happened to be. The mujtahid is only carrying out the will of God in rebelling against secular authority and trying to establish a theocratic state in which he will be the sole interpreter of God's will in all matters. Besides, mujtahids receive good fees for settling disputes which in a well-ordered state would be dealt with far less expensively in the regular courts. Then most of the chief mujtahids are of Persian origin, and all are in constant communication with the priesthood of Persia, which has long been anti-British.

7. The delay in the peace negotiations. The Arab is extremely impatient. Many of the officials who have had to do with the settlement of disputes in Mesopotamia maintain that the Arab would sooner have an adverse decision at once than linger in doubt even with the possibility of success in the end, and the uncertainty as to the fate of the occupied portions of the Ottoman Empire was certainly a cause of unrest.

8. The increase in the power and wealth of the sheikhs. It was an ironical result of the British policy of working through the sheikhs that that policy of itself created enemies to the British authorities. Some of the leaders of the revolt on the Euphrates were men who had been raised from nothing to positions of wealth and power by the support of the British administration.

9. By adopting an attitude of sympathy towards the tribal cultivators against their absentee town landlords who wanted to enforce at their face value title-deeds which in many cases had been unenforceable under the Turks, the British authorities lost the support of many of such landowners. On the other hand, the tribes were too much in the hands of the sheikhs to be able to evince any gratitude they may have felt towards the Government which had defended their interests.

10. The increase in prices, and certain restrictions necessitated by the exigencies of the military campaign.

11. The demands for labour on flood-banks. It is true that the Turks used to call up cultivators for this purpose (the right of Government to call up labour is not disputed), and that the flood-banks are to protect the cultivators' own crops; but the British authorities perhaps set too high a standard for the Arab, and exceptionally high floods increased the difficulty. To the Arab a flood is an act of God against which repining would be impious as well as useless; but if Government tries to make him mend a flood-bank to protect his crops—why, there *is* a remedy.

12. The extension of orderly government, preventing crime and collecting taxes, to areas which had lived almost untouched by the Turkish administration. Land taxation was not heavier than in Turkish times; on the contrary, the rate was lowered in many districts, and the 2½% cesses imposed by the Turks have never been collected since the occupation. But taxes have been collected more regularly, and collected from some areas which had usually escaped payment; and it was not to be expected that the obvious fact that he was, on the whole, far richer and had raised his standard of living, would weigh with the wild Arab "whose sense is in his eye" and who thought he could get all the benefits that flowed from Government enterprise and the maintenance of order without the expense of contributing to the upkeep of the Government.

Above are enumerated the most important of the causes of the 1920 rising, which, it must be remembered, by no means affected the whole country. The great Muntafik confederation did not rise, nor did the Albu Mohammed and other tribes on the Tigris, so turbulent in Turkish times. What weight Arab nationalist propaganda had with the tribes which took part in the rising it is impossible to determine. Some Shiah mujtahids preached a holy war and used the religious argument, while clever Sunni leaders promised a reduction in taxation; and some tribes concerned were frankly after loot and nothing else. Yet it cannot be doubted that the rising must be attributed to some extent to the influence of the idea of an independent Arab state—an idea which was almost non-existent in Mesopotamia before the war. Since the Turkish conquest of the 13th century the Arabs of Mesopotamia have always been under foreign domination, and during the first two or three years of the British occupation the only political question which occupied the inhabitants was whether a British amurath would succeed the Turkish or whether after the war the Turk would return; and their attitude towards the invader depended on their decision as to the respective chances of the Allies and the Central Powers. But the alliance between the Allies and the Sherif of Mecca (now recognized as King of the Hejaz), the departure of many Mesopotamians—formerly in the Turkish army—to fight with the Hejaz Arabs against the Turks, and the talk of Arab independence could not fail to affect Mesopotamia. There is a striking contrast between the speech of Lord Hardinge at Basra, in Feb. 1915, and the proclamation issued by Gen. Maude, on instructions from H.M. Government after the capture of Bagdad, little more than two years later. All that Lord Hardinge could say was that "we might be permitted to indulge in the confident assurance that thenceforth a more benign administration would bring back to Mesopotamia that prosperity to which her rich potentialities entitled her." Gen. Maude's proclamation struck a very definite note. It announced that the British forces had come not as conquerors but as liberators, and pointed out that a long trade connexion had existed between Bagdad and Great Britain, and that the British Government could not remain indifferent to what took place in Mesopotamia, and was determined not to permit again that which had been done in Bagdad by the Turks and Germans. The proclamation continued:—

"But you, the people of Bagdad, whose commercial professions and whose safety from oppression and invasion must ever be a matter of the closest concern to the British Government, are not to understand that it is the wish of the British Government to impose upon you alien institutions. It is the hope of the British Government that the aspirations of your philosophers and writers shall be realized once again. The people of Bagdad shall flourish and enjoy their wealth and substance under institutions which are in consonance with their sacred laws and their racial ideal. In the Hejaz the Arabs have expelled the Turks and Germans who oppressed them and have proclaimed Sherif Husain as their king and His Lordship rules in independence and freedom and is the ally of the nations who are fighting against the power of Turkey and Germany. So, indeed, are the noble Arabs, the Lords of Najd, Kuwait and Asir. Many noble Arabs have perished in the cause of freedom at the hands of those alien rulers, the Turks, who oppressed them. It is the determination of the Government of Great Britain and the Great Powers allied to Great Britain that these noble Arabs shall not have suffered in vain. It is the desire and hope of the British people and the nations in alliance with them that the Arab race may rise once more to greatness and renown amongst the peoples of the earth and that it shall bind itself to this end in unity and concord. O, people of Bagdad! Remember that for 26 generations you have suffered under strange tyrants who have ever endeavoured to set one Arab house against another in order that they might profit by your dissensions. Therefore, I am commanded to invite you, through your nobles and elders and representatives, to participate in the management of your civil affairs, in collaboration with the political representatives of Great Britain who accompany the British army, so that you may unite with your kinsmen in the north, east, south and west in realising the aspirations of your race."

This rather flamboyant proclamation attracted little attention in Bagdad at the time, but it was destined to be quoted later. But it must not be thought, as some harassed officials in Meso-

potamia may well have thought, that the proclamation was a wanton and quite uncalled-for attempt to thrust on the country a form of government for which it was totally unfitted: it was part of the Allies' general Middle Eastern policy, a policy which was defined, in the Anglo-French Declaration of Nov. 8 1918, as having for its object " the complete and definite liberation of the peoples so long oppressed by the Turks and the establishment of National Governments and Administrations drawing their authority from the initiative and free choice of the indigenous populations." Unhappily, it is not easy, in an oriental country, to find out what the people do want. Early in 1919 an attempt was made by the British Government through the British political officers in Mesopotamia to find out what public opinion in Mesopotamia was on three questions of importance:— (1) Should Mosul be included in Mesopotamia? (2) Should Mesopotamia be ruled by an Arab emir? (3) Who should be emir, if an emir was wanted?

The opinions, taken at their face value, showed that Mesopotamia insisted on the union of Mosul with Bagdad and Basra, and on the whole did not want an emir, at any rate for a few years, though a few individuals or groups asked that one of the sons of the Sherif of Mecca should be made emir. It is impossible to say how far the answers were influenced by the universal desire of the East to give the reply which it is believed the questioner wants; nor can any reply, except a denial and a reference to the conduct of British officials in the East in general, be given to critics who say the " plebiscite " was rigged by the political officers. On the other hand, it is easy to see the difficulty of introducing Western electoral systems among tribal Arabs who regard registration for whatsoever purpose as a certain preliminary to taxation or military service.

*Prospects for Mesopotamia.*—The political future of Mesopotamia was not easy to forecast in 1921. The mandate for that country had been conferred on the Government of His Britannic Majesty by the principal Allied Powers, and a draft mandate was submitted by Mr. Balfour on Dec. 7 1920 to the Secretariat-General of the League of Nations for the approval of the Council of the League of Nations.

The idea of a mandate—the issue of a sort of power of attorney by a group of states to one of their number for the administration of a given country—was new, and the novelty was emphasized by the nature of the draft mandate. While entrusted with the control of the foreign relations of Mesopotamia (Article 3) and authorized to maintain troops in the country (Article 2), the mandatory is bound to facilitate the progressive development of Mesopotamia as an independent state (Article 1): to see that no Mesopotamian territory shall pass under the control of the Government of any foreign Power (Article 4); to ensure freedom of conscience and the free exercise of all forms of worship, subject only to the maintenance of public order and morals (Article 8); to see that there is no discrimination in Mesopotamia against the nationals of any State, member of the League of Nations, as compared with the nationals of the mandatory or of any foreign State, in matters concerning taxation, commerce or navigation, the exercise of industries or professions, or in the treatment of ships or aircraft (Article 11); and to secure the enactment within a year of a law of antiquities which shall ensure equality of treatment in the matter of archaeological research to the nationals of all States, members of the League of Nations (Article 14). The immunities and privileges of foreigners, including the benefits of consular jurisdiction and protection as formerly enjoyed by Capitulation or usage in the Ottoman Empire, are definitely abrogated in Mesopotamia (Article 5); but the mandatory is responsible for seeing that the judicial system established in Mesopotamia shall safeguard the interests of foreigners (Article 6). To safeguard the mandatory from financial loss in the execution of the terms of the mandate Article 20 declares that, " in the event of the termination of the mandate . . . the Council of the League of Nations shall make . . . arrangements . . . for securing, under the guarantee of the League, that the Mesopotamian Government will fully honour the financial obligations legally incurred by the mandatory during the period of the mandate, including the rights of public servants or gratuities."

The Anglo-French Declaration of Nov. 8 1918 stated that it was the aim of His Majesty's Government to establish in Mesopotamia a national government and administration deriving their authority from the initiative and free choice of the indigenous populations; and Mesopotamia has been treated by the Allied Powers as one of those " Communities formerly belonging to the Turkish Empire " which " have reached a stage of development where their existence as independent nations can be provisionally recognized, subject to the rendering of administrative advice and assistance by a mandatory Power until such time as they are able to stand alone " (Treaty of Versailles).

In 1921, pending the election of a constituent assembly, Mesopotamia was being governed by the High Commisioner and a provisional Arab Government over which the Naqib of Bagdad presided. There had been much discussion, both in Mesopotamia and in the English press, of the question of the selection of an emir for Mesopotamia. The idea, which did not appear to have been generally approved by the people of Mesopotamia early in 1919, seemed to be widely accepted by them in 1921, though there was much discussion as to the person to be chosen. Owing to the prominent part taken by the sons of the King of the Hejaz during the war, two of them, 'Abdalla and Faisal, were the favourite candidates for the Mesopotamian throne. Eventually, at the invitation of some of his supporters in Mesopotamia, Faisal came forward definitely as a candidate, and went to Mesopotamia to press his suit, and his brother 'Abdalla resigned his claim. On his arrival Faisal was given a warm reception by the people of Mesopotamia, such other candidates as there were withdrew, and the Arab Council of State, on the motion of the president (the Naqib of Bagdad), passed a resolution declaring that Faisal should be regarded as having been chosen ruler of Iraq by acclamation provided that he would consent to rule as a constitutional, democratic sovereign. It had been intended to submit the question of the rulership to an assembly elected under a system based on the Ottoman electoral law, but, as this would have taken some months and the matter was pressing, a referendum was carried out. The result was overwhelmingly in favour of the Emir Faisal. A few extremists in Bagdad made their approval conditional on his being free from foreign influence, while the Basra people, on the contrary, promised their support only for so long as he should maintain the connexion with Great Britain; but on the whole the approval was unanimous and unconditional, and Faisal was accordingly crowned King of Iraq at Bagdad on Aug. 23 1921.

In the course of a speech made at the accession ceremony King Faisal expressed his gratitude to the British nation for its aid in the cause of Arab liberation and independence, and declared that it was from the British nation alone that they should seek help in order to reach their goal. He added: " My first task will be to proceed with the elections and the convocation of the Constituent Assembly. The nation should understand that it is this Congress that will, in consultation with me, draw up the constitution of its independence, on the basis of democratic government, and define the fundamental principles of political and social life. Finally it will confirm the Treaty which I shall lay before it in regard to the relations which are to exist between our Government and the great British Government."

In this fashion was inaugurated the policy described by the British Secretary of State for the Colonies, Mr. Winston Churchill, in his speech in the House of Commons on June 14 1921, as having for its object " to reduce our commitments and extricate ourselves from our burdens, while at the same time discharging our obligations and building up an effective Arab Government which would always be the friend of Britain." Concurrently with the political development of the Arab State, Mr. Churchill explained, there would be created and developed local military forces which would gradually replace most of the British troops. By the end of the financial year 1921–2 the British forces would be reduced to about 12 battalions of infantry, but there would also be the nucleus of an Arab army, maintained

by the Mesopotamian treasury, and certain frontier levies, consisting partly of Kurds and partly of Assyrians enlisted from among the refugees. In addition there were arrangements for maintaining public security by means of a powerful air force.

The Kurdish portion of the mandated territory was (1921) in a special position. Article 62 of the Treaty of Sèvres provided for the elaboration of a scheme of autonomy for that part of Kurdistan which lies north of Mesopotamia, east of the Euphrates and south of Armenia; and Article 64 provided that if the Kurds in that area asked for autonomy within a year of the signature of peace with Turkey, " the Kurds inhabiting that part of Kurdistan which has hitherto been included in the Mosul vilayet " might declare their voluntary adhesion to that autonomous state. Article 16 of the final draft of the mandate for Mesopotamia is in harmony with this. It declares that " nothing in this mandate shall prevent the mandatory from establishing a system of local autonomy for predominantly Kurdish areas in Mesopotamia as he may consider suitable."

It may be convenient to summarize the arguments advanced on both sides in the discussion in 1921 as to the stability of the Mesopotamian state. The sceptical pointed to the following difficulties:—

1. Lack of unity among the people of Mesopotamia. The Arabs never have agreed and never will. The Shiahs, who were formerly in a minority and repressed by the Sunni Turks and their Sunni Arab adherents, are now in the majority, and will not tolerate government by Sunnis, while all the men with secular education and experience sufficient to qualify them for high office are Sunnis. Moreover, the Shiahs are under the influence of their mujtahids.
2. Lack of security. The Turks were not able to keep order in Mesopotamia. Can an Arab Government do what was beyond the powers of the Turks, especially now that every tribesman possesses a modern rifle?
3. Lack of funds. An Arab Government will lack the authority to collect the revenue necessary to pay the Government officials—particularly the forces of law and order.
4. Possible trouble on the border, instigated or exacerbated by propaganda from outside.

To these arguments it was replied:—

1. The establishment of an Arab Government and the accession of an emir will draw the Arabs of Mesopotamia together.
2. It is not proved that an Arab Government cannot maintain security, and if it were, why should an Arab Government insist on the degree of security which British officials demand? And finally, if an Arab Government can keep order not less well than the Turks did (not a high standard) they must be held to have succeeded.
3. Being content with a simpler organization than would be expected under a British administration, the Arab Government will not require a large income, and they can afford to tax lightly where—as, for example, in the case of land revenue—heavier taxation might rouse opposition. Probably they will depend in the main on customs dues, which provide more than half the local revenue, are relatively easy to collect, and are not resented by the taxpayer.
4. The mandatory and the people of Mesopotamia must be prepared for predatory raids by Kurdish tribes from over the border and Arab tribes from the desert, but with the conclusion of the outstanding treaties of peace and the gradual settling down of the world after the war little foreign intrigue is to be apprehended.

### Lines of Economic Development

Contradictory views as to the possibility of agricultural and other economic development in Mesopotamia are held by authorities. Some maintain that Mesopotamia was formerly and could be again " the granary of the world "; others that the numerous population of Babylon in the time of Herodotus lived mainly by trade and not by agriculture, and that in any case there is too little water or too much salt in the ground or too sparse a population for any considerable extension of agriculture. There are, however, some definite facts which bear upon the conclusion to be reached on this point.

*Agriculture.*—Any considerable extension of agriculture depends on the fulfilment of one or more of the following requirements:—

1. Increase of population. Before the British occupation the rate of increase was retarded by heavy child mortality, high death-rate from epidemics, and the deaths resulting from blood feuds and tribal fighting. How far these causes will operate in future depends on the ability of the Government to maintain order, to improve sanitary conditions, and to provide medical aid. The settlement of nomads or semi-nomads is always going on, but this is an almost imperceptible process, and in any case it must be remembered that the nomad is also a source of wealth in that he breeds camels and sheep; consequently the settlement of nomads is not a net gain to the country. There may be a slight influx of Kurds from the north, but the experience of the Erbil area during the last few decades leads one to believe that the result of such influx would merely be the displacement of the less industrious Arab cultivator. Immigration from overseas is not likely to attain large proportions. The climate precludes the pursuit of agriculture by European settlers, while the immigration of Asiatics would probably be regarded with some distrust and fear by the Arabs.
2. Improvement in methods of cultivation. Much has already (1921) been done to introduce better implements of a simple kind, *e.g.* ploughs, to improve field drainage, to study local diseases of plants, and to secure clean barley and wheat seed. Moreover, tractors and mechanical implements have been introduced, and their work, under the auspices of the Agricultural Department, is being watched with interest by many landowners.
3. Extension of irrigation. In order to increase local food supplies and thus to economize in money and shipping, the British military authorities in 1917 formed a small Irrigation Department. It was not possible to take up large schemes, but the Hindiya barrage was kept working, miles of flood-banks were built, a canal taking off just above the barrage, which had been begun before the war, was completed and its sister canal dug; the Saqlawiya canal, which used to flood the country west of Bagdad, was brought under control by the construction of a regulator, and many old canals were cleared and made serviceable. Perhaps the most important work has been the construction of regulators at the head of some of the largest of the Tigris canals. The effect of this is not merely to save water which would be wasted in the marshes, but, by throwing more water down the river, to scour out its bed and thus facilitate navigation and prevent flooding.

It seemed probable in 1921 that no large schemes would be undertaken for the present, and that the limited funds available would be used mainly in carrying out a comprehensive survey which would serve as a basis for extensive irrigation schemes later.

Experiments have been made with products previously not grown at all, or grown without scientific attention. In the first category are ground-nuts and sugar-beet, in the latter cotton. It is too soon to dogmatize about Mesopotamian cotton, but the experiments of 1918–21 tend to show that it has a fairly long staple and should fetch a good price in the world market.

*Mineral Wealth.*—Of minerals, oil occupies the attention of the world. The signs of oil in many places, from Mandali in the latitude of Bagdad to Zakho north of Mosul, and the existence of profitable wells in Persia not far from the Mesopotamian frontier, have induced in the mind of the public the belief that Mesopotamia is another Mexico for petroleum, but in 1921 there was no certain knowledge that petroleum existed in Mesopotamia in quantities to repay the cost of exploitation. Near Kifri there is a so-called coal-mine, which was worked by the Turks during the war when they had no other fuel for their steamers, but the " coal " has been pronounced by experts to be only inspissated petroleum, and has been proved in practice to be of little or no value. Bitumen is found at several places, notably Hit on the Euphrates, but it is doubtful whether the supply is more than sufficient for local needs.

*Currency.*—The Indian currency is now in use everywhere in Mesopotamia. On account of the close trade connexions with India the rupee was well known in Basra before the war, and passed in the bazaar on equal terms with Turkish money and the Persian kran. The payment of large bills in Indian currency by the British forces caused Turkish silver and copper to disappear rapidly before the silver rupee and the Indian note. This process was repeated in every town occupied: there was a short period of hesitation, and then the replacement of the old currency by the new was effected in a few days. In the more remote parts of Mesopotamia Indian notes have usually been at a small premium, owing to the convenience of carriage. The Turkish gold lira is still used in the bazaar sometimes for large transactions.

*Banks.*—Before the war the only bank operating in Mesopotamia was the Imperial Ottoman Bank. In addition there are now branches of the Imperial Bank of Persia and the Eastern Bank.

*Trade.*—Table 2 shows in sterling, calculated on the basis of 15 rupees to the pound, the total value of imports and exports for the port of Basra for each year during the periods 1910–2 and 1917–9.

Table 2.—Trade.

| | Imports | Exports |
|---|---|---|
| 1910 . . | £2,633,000 | £1,666,000 |
| 1911 . . | 2,853,000 | 2,526,000 |
| 1912 . . | 2,653,000 | 3,246,000 |
| 1917 . . | 4,033,000 | 820,000 |
| 1918 . . | 7,400,000 | 900,000 |
| 1919 . . | 9,326,000 | 2,406,000 |

In addition, the figures for Bagdad, both for sea-borne trade and for trade by land, for 1919, were:—Imports, £2,940,000; exports, £4,940,000.

The principal imports and exports (figures for Bagdad and Basra combined) are shown in Tables 3 and 4. In some cases figures for 1912 also are given.

TABLE 3.—Imports.

| | 1912 | 1919 |
|---|---|---|
| Textiles | £1,320,000 | £6,380,000 |
| Sugar | 293,000 | 1,453,000 |
| Tea | — | 433,000 |
| Grain and Flour | — | 433,000 |
| Tobacco | — | 426,000 |
| Carpets | — | 280,000 |
| Liqueurs | — | 193,000 |
| Cigarette-papers and smokers' requisites | — | 175,000 |
| Metals and Ores | 733,000 | 166,000 |
| Soap | — | 153,000 |

TABLE 4.—Exports.

| | 1912 | 1919 |
|---|---|---|
| Dates | £466,000 | £1,470,000 |
| Piece Goods | — | 3,540,000 |
| Grain: Barley | 1,120,000 | |
| Grain: Wheat | 240,000 | 190,000 |
| Grain: Paddy | 326,000 | |
| Wool | 300,000 | 160,000 |
| Carpets | — | 240,000 |
| Sugar | — | 530,000 |
| Tea | — | 225,000 |

Nearly the whole of the piece goods, sugar and tea shown in the exports for 1919 were destined for Persia.

Deductions based on these figures have to be made with caution. The figures give total values, not quantities; consequently the rise in prices between 1912 and 1919 has to be taken into account. Moreover, several abnormal causes contributed to bring about an increase in imports into Mesopotamia. The closing of the Caucasus route diverted to Mesopotamia trade which would ordinarily have gone to Persia via Batum, Baku and the Caspian; the large purchases in Mesopotamia, both by the army authorities and by the troops, gave increased purchasing power to the country; the depletion of stocks during the war led to a rush of trade the moment shipping became available; and the rise in the value of the rupee, considerable during the war and very marked in 1919–20, led to abnormally large purchases. Nevertheless it may be taken for granted that a greater volume of trade will flow into and through Mesopotamia than before the war, if only because: (1) the Caucasus route is not likely to be safe, expeditious and cheap for some time; (2) the Mesopotamian railway system favours the Bagdad route to Persia; (3) the standard of living in Mesopotamia has been raised considerably during the war; and (4) the economic development begun during the war is certain to encourage enterprise.

*Communications.*—The exigencies of the campaign compelled the British military authorities to maintain a large fleet of river steamers on the Tigris, and this involved the adoption of measures to facilitate navigation. The whole course of the navigable channel has been marked by buoys or by signs erected on the banks, and efforts have been made with considerable success to improve the bed of the river. At Basra a modern port has been constructed; whereas before the war cargo had to be unloaded from steamers into lighters in mid-stream, ocean-going steamers can now come alongside and discharge cargo on to the wharves or railway trucks.

A dictum attributed to Sir William Willcocks, that it would pay Mesopotamia to use all the water from the Tigris and the Euphrates for irrigation and to rely on railways for transport, is not likely to be regarded as practical politics for a very long while. In 1921 there was far more traffic on the Tigris than before the war. The Turkish Government fleet had disappeared as an organization; but, on the other hand, the successors of Messrs. Lynch were no longer restricted to three boats, and in addition many other companies and individuals ran boats purchased from the British military authorities when the river war fleet was reduced. The bed of the Tigris has been improved on the most difficult stretch, and the control of the canals should effect further improvements.

In 1914 Mesopotamia had only 70 m. of railway—a standard-gauge line running from Bagdad northwards to Samarra. This was intended to be linked up with the Bagdad railway, the main portion of which ran from Constantinople through Konia and Aleppo to Nisibin (1917), about 100 m. north-west of Mosul. By 1920 there was a network of railways in Mesopotamia: in metre gauge, Basra to Bagdad (about 354 m.), Bagdad to the Persian frontier (about 130 m.), with extension to Kifri (about 50 m.), and Bagdad to Kut (about 104 m.); in standard gauge, Bagdad via Samarra to Sherghat (about 186 m.). There was also a narrow-gauge line from Bagdad to Falluja, on the Euphrates—a distance of about 30 miles. All these railways, the standard-gauge line excepted, were built by the British military authorities as part of the plan of campaign.

Basra and Bagdad are connected by railway, but it was not yet possible in 1921 to travel from one end of Mesopotamia to the other by rail. The section of the Bagdad railway built by the Germans from Bagdad to Samarra was extended for war purposes as far as Sherghat, [illegible] about 70 m. south of Mosul; but as it passes through desert for a great part of its length it is unprofitable as a commercial undertaking, and it may be decided to take up the Samarra–Sherghat extension and to establish communication with Mosul by continuing the line from Kifri through the wheat-growing country and the considerable towns of Kirkuk, Altun Köprü and Erbil. No official decision as to military communication with the Mediterranean had yet been published in 1921. Some authorities desired to see the Mesopotamian system connected with the Bagdad railway, which has reached Nisibin, about 100 m. north of Mosul; others would prefer a line across to some port in Palestine. The pilgrim traffic from Persia would, it is believed, justify the construction of a line to connect the Shiah towns of Najaf and Karbala with the existing lines.

The port of Basra is large enough, and sufficiently well supplied with facilities for unloading, to deal with the trade of Mesopotamia for some years to come. It can deal with larger ships than the Fao bar at the mouth of the Shatt al 'Arab will allow to pass, but plans for the dredging of this bar were being made.

*Archaeology.*—All systematic archaeological research was suspended by the war. The antiquities of Mesopotamia were protected by a Proclamation issued by the General Officer Commanding in Chief in 1917. Article 14 of the draft mandate is of importance to archaeologists. It says:—

"The mandatory will secure the enactment within twelve months from the coming into force of this mandate, and will ensure the execution of a Law of Antiquities, based on the contents of Article 421 of Part XIII. of the Treaty of Peace with Turkey. This law shall replace the former Ottoman Law of Antiquities, and shall ensure equality of treatment in the matter of archaeological research to the nationals of all States, members of the League of Nations."

Some of the Sherghat antiquities, which were being sent to Berlin by the German archaeologists who carried out the excavations, were captured by the Portuguese on the outbreak of war and were declared lawful prize by the Portuguese Government. Certain cases of antiquities collected by a German mission in Samarra before the war were found in Mesopotamia. Having neither the staff nor the facilities for dealing with such treasures, and fearing that they would deteriorate, the Mesopotamian authorities sent the cases to the British Museum to be examined and catalogued.

**MESSEL, RUDOLPH** (1848–1920), Anglo-German chemist, was born at Darmstadt Jan. 14 1848, and educated at the universities of Zürich, Heidelberg and Tübingen. He came to England in 1870 and acted as assistant to J. C. Calvert and later to Sir Henry Roscoe at Manchester. He then took up industrial chemistry and made notable experiments, especially in connexion with processes for obtaining sulphuric acid (*see* 26.68) for use in alizarin manufacture. He died in London April 18 1920.

**METALLURGY** (*see* 18.203).—The progress in metallurgy after 1911 was profoundly affected by the incidence of the World War. Modern warfare is so entirely dependent upon the products of metallurgy that the effort to secure military victory to some extent resolved itself into struggle for supremacy in metallurgical output by the opposing nations. This applied most directly, perhaps, to steel products such as guns and shells, ship-plates and armour plates, etc., but it also applied to copper and its alloys, to zinc, to lead and antimony, and, in a special degree, to aluminium. During the war period, therefore, the progress of metallurgy became mainly a relentless struggle for output in which, in some directions, quality was ruthlessly sacrificed and heavy "war risks" were cheerfully taken. After the termination of the war, industrial conditions became extremely unsettled and difficult; for a time there was still a great shortage of ships; then followed acute industrial disturbances, particularly in England, while the war-scarred Continental nations only slowly resumed their normal activities, which were gravely hindered on all sides by the direct and indirect economic consequences of the Treaty of Versailles.

The whole period under review (1910–21), therefore, falls into two main divisions—prior to Aug. 1914 and the period of the war and after. During the former period there was a steady development both of metallurgical science and practice, but both were rudely deflected by the war. None the less, the stress of war conditions has produced a large amount of important progress, but in many directions full knowledge of what had been attained is only now reaching publicity. We were still in 1921 too near the World War to be able to appreciate its real

by the Mesopotamian treasury, and certain frontier levies, consisting partly of Kurds and partly of Assyrians enlisted from among the refugees. In addition there were arrangements for maintaining public security by means of a powerful air force.

The Kurdish portion of the mandated territory was (1921) in a special position. Article 62 of the Treaty of Sèvres provided for the elaboration of a scheme of autonomy for that part of Kurdistan which lies north of Mesopotamia, east of the Euphrates and south of Armenia; and Article 64 provided that if the Kurds in that area asked for autonomy within a year of the signature of peace with Turkey, " the Kurds inhabiting that part of Kurdistan which has hitherto been included in the Mosul vilayet " might declare their voluntary adhesion to that autonomous state. Article 16 of the final draft of the mandate for Mesopotamia is in harmony with this. It declares that " nothing in this mandate shall prevent the mandatory from establishing a system of local autonomy for predominantly Kurdish areas in Mesopotamia as he may consider suitable."

It may be convenient to summarize the arguments advanced on both sides in the discussion in 1921 as to the stability of the Mesopotamian state. The sceptical pointed to the following difficulties:—

1. Lack of unity among the people of Mesopotamia. The Arabs never have agreed and never will. The Shiahs, who were formerly in a minority and repressed by the Sunni Turks and their Sunni Arab adherents, are now in the majority, and will not tolerate government by Sunnis, while all the men with secular education and experience sufficient to qualify them for high office are Sunnis. Moreover, the Shiahs are under the influence of their mujtahids.
2. Lack of security. The Turks were not able to keep order in Mesopotamia. Can an Arab Government do what was beyond the powers of the Turks, especially now that every tribesman possesses a modern rifle?
3. Lack of funds. An Arab Government will lack the authority to collect the revenue necessary to pay the Government officials—particularly the forces of law and order.
4. Possible trouble on the border, instigated or exacerbated by propaganda from outside.

To these arguments it was replied:—

1. The establishment of an Arab Government and the accession of an emir will draw the Arabs of Mesopotamia together.
2. It is not proved that an Arab Government cannot maintain security, and if it were, why should an Arab Government insist on the degree of security which British officials demand? And finally, if an Arab Government can keep order not less well than the Turks did (not a high standard) they must be held to have succeeded.
3. Being content with a simpler organization than would be expected under a British administration, the Arab Government will not require a large income, and they can afford to tax lightly where—as, for example, in the case of land revenue—heavier taxation might rouse opposition. Probably they will depend in the main on customs dues, which provide more than half the local revenue, are relatively easy to collect, and are not resented by the taxpayer.
4. The mandatory and the people of Mesopotamia must be prepared for predatory raids by Kurdish tribes from over the border and Arab tribes from the desert, but with the conclusion of the outstanding treaties of peace and the gradual settling down of the world after the war little foreign intrigue is to be apprehended.

### Lines of Economic Development

Contradictory views as to the possibility of agricultural and other economic development in Mesopotamia are held by authorities. Some maintain that Mesopotamia was formerly and could be again " the granary of the world "; others that the numerous population of Babylon in the time of Herodotus lived mainly by trade and not by agriculture, and that in any case there is too little water or too much salt in the ground or too sparse a population for any considerable extension of agriculture. There are, however, some definite facts which bear upon the conclusion to be reached on this point.

*Agriculture.*—Any considerable extension of agriculture depends on the fulfilment of one or more of the following requirements:—

1. Increase of population. Before the British occupation the rate of increase was retarded by heavy child mortality, high death-rate from epidemics, and the deaths resulting from blood feuds and tribal fighting. How far these causes will operate in future depends on the ability of the Government to maintain order, to improve sanitary conditions, and to provide medical aid. The settlement of nomads or semi-nomads is always going on, but this is an almost imperceptible process, and in any case it must be remembered that the nomad is also a source of wealth in that he breeds camels and sheep; consequently the settlement of nomads is not a net gain to the country. There may be a slight influx of Kurds from the north, but the experience of the Erbil area during the last few decades leads one to believe that the result of such influx would merely be the displacement of the less industrious Arab cultivator. Immigration from overseas is not likely to attain large proportions. The climate precludes the pursuit of agriculture by European settlers, while the immigration of Asiatics would probably be regarded with some distrust and fear by the Arabs.
2. Improvement in methods of cultivation. Much has already (1921) been done to introduce better implements of a simple kind, *e.g.* ploughs, to improve field drainage, to study local diseases of plants, and to secure clean barley and wheat seed. Moreover, tractors and mechanical implements have been introduced, and their work, under the auspices of the Agricultural Department, is being watched with interest by many landowners.
3. Extension of irrigation. In order to increase local food supplies and thus to economize in money and shipping, the British military authorities in 1917 formed a small Irrigation Department. It was not possible to take up large schemes, but the Hindiya barrage was kept working, miles of flood-banks were built, a canal taking off just above the barrage, which had been begun before the war, was completed and its sister canal dug; the Saqlawiya canal, which used to flood the country west of Bagdad, was brought under control by the construction of a regulator, and many old canals were cleared and made serviceable. Perhaps the most important work has been the construction of regulators at the head of some of the largest of the Tigris canals. The effect of this is not merely to save water which would be wasted in the marshes, but, by throwing more water down the river, to scour out its bed and thus facilitate navigation and prevent flooding.

It seemed probable in 1921 that no large schemes would be undertaken for the present, and that the limited funds available would be used mainly in carrying out a comprehensive survey which would serve as a basis for extensive irrigation schemes later.

Experiments have been made with products previously not grown at all, or grown without scientific attention. In the first category are ground-nuts and sugar-beet, in the latter cotton. It is too soon to dogmatize about Mesopotamian cotton, but the experiments of 1918–21 tend to show that it has a fairly long staple and should fetch a good price in the world market.

*Mineral Wealth.*—Of minerals, oil occupies the attention of the world. The signs of oil in many places, from Mandali in the latitude of Bagdad to Zakho north of Mosul, and the existence of profitable wells in Persia not far from the Mesopotamian frontier, have induced in the mind of the public the belief that Mesopotamia is another Mexico for petroleum, but in 1921 there was no certain knowledge that petroleum existed in Mesopotamia in quantities to repay the cost of exploitation. Near Kifri there is a so-called coal-mine, which was worked by the Turks during the war when they had no other fuel for their steamers, but the " coal " has been pronounced by experts to be only inspissated petroleum, and has been proved in practice to be of little or no value. Bitumen is found at several places, notably Hit on the Euphrates, but it is doubtful whether the supply is more than sufficient for local needs.

*Currency.*—The Indian currency is now in use everywhere in Mesopotamia. On account of the close trade connexions with India the rupee was well known in Basra before the war, and passed in the bazaar on equal terms with Turkish money and the Persian kran. The payment of large bills in Indian currency by the British forces caused Turkish silver and copper to disappear rapidly before the silver rupee and the Indian note. This process was repeated in every town occupied: there was a short period of hesitation, and then the replacement of the old currency by the new was effected in a few days. In the more remote parts of Mesopotamia Indian notes have usually been at a small premium, owing to the convenience of carriage. The Turkish gold lira is still used in the bazaar sometimes for large transactions.

*Banks.*—Before the war the only bank operating in Mesopotamia was the Imperial Ottoman Bank. In addition there are now branches of the Imperial Bank of Persia and the Eastern Bank.

*Trade.*—Table 2 shows in sterling, calculated on the basis of 15 rupees to the pound, the total value of imports and exports for the port of Basra for each year during the periods 1910–2 and 1917–9.

Table 2.—Trade.

| | Imports | Exports |
|---|---|---|
| 1910 . . | £2,633,000 | £1,666,000 |
| 1911 . . | 2,853,000 | 2,526,000 |
| 1912 . . | 2,653,000 | 3,246,000 |
| 1917 . . | 4,033,000 | 820,000 |
| 1918 . . | 7,400,000 | 900,000 |
| 1919 . . | 9,326,000 | 2,406,000 |

In addition, the figures for Bagdad, both for sea-borne trade and for trade by land, for 1919, were:—Imports, £2,940,000; exports, £4,940,000.

The principal imports and exports (figures for Bagdad and Basra combined) are shown in Tables 3 and 4. In some cases figures for 1912 also are given.

has arisen as to the importance or otherwise of such "temper brittleness" on the ground that it can only be detected by a particular form of test—the "notched bar impact test." Hatfield has repeatedly suggested that this test measures a property of no practical importance and that, therefore, temper brittleness is only "apparent" and not "real." This view, however, has not been generally accepted, since a number of investigators (Rosenhain, Greaves and others) have found a very distinct correlation between a low value under the notched bar impact test and cases of actual failure in service.

For certain purposes, where simple nickel steels are not found adequate, a chrome-vanadium steel has been extensively used. The fact that vanadium plays a really important rôle in such steels has come to be recognized, but there are still difficulties in its metallurgical applications. For quite a different range of purposes a steel containing relatively large amounts of chromium (about 13%, Brearley) has found wide applications. Its best-known application is to the production of "stainless" cutlery which is proving extremely successful in practice and, in spite of the relatively high cost, is coming into extensive use as a labour-saving device. Some difficulty was at first experienced in hardening this material satisfactorily; it requires a higher quenching temperature than cutlery-hardeners have been accustomed to employ (Hatfield), and, as a consequence, the earlier products were insufficiently hardened and gave rise to the complaint that such cutlery would not keep its edge. Recent practice has overcome this defect, although the fact still remains that "stainless" knives, not being automatically sharpened by daily polishing, require careful sharpening from time to time. The applications of this steel to other purposes where resistance to corrosion is important are being found almost daily. Incidentally, it was found that this steel is capable of resisting the severe conditions which occur in the service of an exhaust-valve in aeroplane engines, although a high-tungsten steel (18% tungsten) has been found to be even slightly better (Aitchison).

*High-speed Steels.*—In the metallurgical progress of the period under review, the development of high-speed cutting steels occupies an important place, their possibilities having been steadily exploited to an increasing extent, their development being naturally accompanied by an evolution of machine-tools capable of utilizing the high-cutting powers of the new steels. Under war conditions, the great demand for tool-steels of this kind created a relatively enormous demand for tungsten, and considerable developments in the mining and production of tungsten took place. Efforts to replace tungsten by other metals were also made, and very great claims were advanced for a "new" high-speed steel in which molybdenum in combination with vanadium was used in place of tungsten (Arnold). The use of molybdenum in place of tungsten, however, was by no means new, and the merits of the new "discovery" therefore depended entirely upon the extent to which the known disadvantages of molybdenum in this connexion had been overcome. Uncertainty of quality and a strong tendency to crack while in the ingot form were the chief of these. Indeed, at the present time, there seems to be no tendency for the normal tungsten high-speed steel to be discarded in favour of the molybdenum-vanadium alloy.

In connexion with high-speed steels, mention may here be made of two alloys which have been used, with considerable success, in place of such steel. These are known as "stellite" and "cooperite" respectively. Stellite consists, according to one reliable analysis, mainly of cobalt 56%, chromium 34%, tungsten 9%, carbon 1%. Actual cutting tests with this material have shown that it is capable of cutting rather faster than the best tungsten steel, provided that the cut is smooth and regular, but that for roughing cuts, where the tool is subjected to sudden shocks and jars, the alloy is unsuited as it is too brittle and the tool frequently breaks off. In the form as ordinarily marketed, moreover, stellite cannot be softened, so that it must be used in the cast condition and the tool has to be ground to shape while hard. Recently, a form of stellite which can be softened has been announced, but no data in regard to it are yet available.

Cooperite is an alloy of nickel, tungsten and zirconium, described as containing 80% of nickel, 14% of tungsten and 6% of zirconium.

*Cobalt Steel.*—Returning to alloy steels, mention must be made of the use of cobalt. The great development of cobalt production at Sudbury in Canada has made this metal available and has attracted interest to its possible uses. A high-speed tool-steel containing cobalt has been produced in Sheffield, and has not only been found to be successful in general use, but to have the remarkable property that it does not undergo any distortion during the hardening process. Should this property be established in practical service the steel is likely to prove of very great importance in the production of shaped cutting tools in which great accuracy is required. War conditions brought with them painful experience of the great difficulty which then existed in the production of accurate parts—such as those of shells and fuzes which were required to be strictly interchangeable. This difficulty extended back to the gauges and master-gauges used for the checking of such parts and, ultimately, in many cases to the cutting-tools used in their production. In other cases, the steel of which the gauges themselves were made gave much trouble owing to distortion during hardening, requiring considerable adjustment by "lapping" of the hardened article.

A cobalt-steel has also made its appearance as an important innovation in another field—that of steels for permanent magnets. Made in the first place of hardened carbon steels, the requirements particularly of the magnetos used for ignition purposes in air-craft engines led to the use of special steels containing about 6% of tungsten. A Japanese invention, based upon extensive researches carried out in that country (Honda), has produced a cobalt magnet steel which, in its best examples, gives very surprising results, combining an exceptionally high coercive force with a relatively large remanence. By the use of this steel a much smaller and lighter magnet would suffice for a magneto of given power. The steel is extremely expensive, and when supplied in quantity appears to vary in quality, while there is also some difficulty in its workshop manipulation. These, however, are probably difficulties arising from the novelty of the product and are likely to disappear as it becomes better understood by the makers.

*Welding.*—One of the most remarkable developments (metallurgical in the wider sense) during the period under review has been that of autogenous welding, both by the oxy-acetylene flame and by the electric arc. Both these processes afford a relatively very cheap and simple means of making joints in metal, particularly in iron and steel, and as the joint consists of "the same metal" as that which is being joined, there is a specious suggestion that the joint is "perfect" in the sense of being as good as the unjointed portions of metal. Although it is quite possible to obtain welded test-pieces which break, under a tensile test, away from the actual joint, the joint itself can never be regarded as equal in strength and toughness to the unjointed steel. There are several reasons for this conclusion. In the first place, the material in the weld itself has simply solidified from fusion and is at best equal in properties to the same steel in the cast condition, while the rest of the plate itself has been immensely improved in quality by forging and rolling and possibly by heat-treatment. Further, adjacent to every such weld there is a region of steel which has either been severely overheated or—a little farther away—which has been heated to a temperature just below the critical range. In both these regions the steel is seriously weakened and it is in the latter that test-pieces generally break. The most serious difficulty, however, is that of being sure that any autogenous weld is truly sound. Examination of many such welds has shown that soundness is very difficult to secure and that it is the exception rather than the rule, even in careful practice; while it is not possible to ascertain by any external examination of a weld whether it is sound or not. Examination by the aid of a powerful X-ray installation can sometimes be employed to assure the soundness of an important weld, but as a rule this is not feasible. It would seem, therefore—and the best-informed opinion is steadily coming to take this view—that welded joints cannot be relied upon to carry severe working stresses, and that they should not be employed in vital parts unless an exceptionally heavy factor of safety can be allowed. Actual experience in aeroplane construction has borne out this view, and a construction in which steel tubes are joined together by pinned and soft-soldered joints has been found more reliable than autogenous welding, provided that the working stress on the solder is kept to a low value. On the other hand, it must be borne in mind that the welding processes afford a ready means of making joints and effecting repairs where no other process could be used, and under war conditions particularly rapid repairs were frequently executed with great success. None the less, many such cases involved very decided "war risks." At the same time, welded joints should not be compared with the unjointed material but rather with joints made in other ways, such as riveting; and there the comparison is much more favourable except for the serious element of uncertainty. The application of welding, and particularly of electric arc welding to such purposes as ship construction, has, however, found considerable acceptance (*see* WELDING).

NON-FERROUS METALS.—The outstanding feature in the progress of non-ferrous metallurgy is undoubtedly summed up in the one word, "flotation." In spite of long-continued litigation, which has resulted in clouding the whole matter in an obscurity from which published scientific research (Sulman, Langmuir) has not yet fully extricated it, this process has made enormous progress and has to a considerable extent revolutionized the entire practice of the extraction of many non-ferrous metals, particularly those occurring in the form of sulphide minerals, such as galena, zinc-blende and the various pyritic copper ores. Its effects have been direct in superseding most gravitational methods of separation, and indirect in view of the fact that flotation deals primarily with very finely divided material, including the "slimes" which were the greatest difficulty of the pre-flotation metallurgist. Not only has this affected ore-grinding and handling practice, but it has brought about a great change in smelting practice also. Thus the treatment of copper concentrates is being carried out to a rapidly increasing extent in the reverberatory furnace to the steady exclusion of the blast furnace.

*Flotation.*—The principles of flotation do not appear to be entirely understood from the physical or physicochemical point of view, as there is considerable divergence of opinion on the question whether flotation phenomena are the result of purely "surface tension" forces or whether electrical forces play an important part. The operations involved are, however, sufficiently clearly defined, and consist essentially of three steps which may overlap or merge into one another. The first of these may be described as the "oiling" process. This consists in adding to the slip or mixture of finely ground ore and water some "oiling" reagent. This may be either an essential oil or one of a great range of chemical substances, generally organic in character. Only a very small amount of such a reagent is used, since the addition of larger quantities produces entirely different effects due to the formation of oil-films of appreciable thickness. The minute amount of oiling reagent, on the other hand, appears to produce some change on the surfaces of certain minerals having a metallic or semi-metallic character—zinc-blende being a typical example—which makes them less readily "wetted" by the liquor of the slip, or, put in another way, increases the angle of contact between these surfaces and the liquid. The gangue of the ore is less affected or not all affected by the oiling reagent, but in many cases it is necessary artificially to increase the difference between mineral and gangue by the addition of some "gangue modifying reagent" which renders the gangue more readily wetted by the aqueous liquid of the slip. These "gangue modifiers" are as a rule alkalies or mineral acids.

The third step in the process consists in adding to the slip some substance which causes the ready production of a stiff and lasting froth when air is introduced, either by agitation or by blowing or drawing it through the liquid in a finely divided state. Very frequently the "oiling reagent" also serves as the froth-producer. When the slip thus prepared is treated so as to produce a froth, the oiled mineral particles adhere to the air-bubbles very firmly, the mineral-air surfaces evidently being the seat of less potential energy than the mineral-water surfaces, and consequently the buoyancy of the combined bubble with its mineral burden causes it to float to the surface where it accumulates as a very stiff mineralized froth which can be mechanically separated in various ways. Actually, a further action appears to take place, which is related to the flocculation of the mineral particles in contact with air-bubbles. This results in the attachment to each bubble of much larger and heavier agglomerations of mineral particles, thus greatly increasing the efficiency of the whole process.

The flotation process has found its largest application in the concentration of various types of sulphide ores and, on this ground alone, has attained very great industrial and technical importance. Its application to other minerals has, however, been actively pursued, and in a great many cases with considerable success. Minerals having a more or less metallic character are particularly suited for flotation, so that native metals constitute an obviously promising application. It is quite possible that ultimately the treatment of finely divided gold-bearing ores may revert to flotation, but as yet the older cyaniding processes in their modern forms continue to hold their own. Application to minerals of the oxide and carbonate type is less simple, and here it seems to be necessary, in many cases, to submit the ore to a previous "activating" treatment. Preliminary roasting in a reducing atmosphere in the hope of producing a more or less metallic surface coating upon the ore particles has been tried, while "sulphidizing" by exposing the finely ground ore to the action of hydrogen (or ammonium-sulphide) has also been tried, in some cases with success. Another problem, which offers the promise of most important results when a full solution has been found, is that of "differential flotation" for the purpose of separating different metalliferous minerals in a complex ore, such as the separation of zinc-blende or sphalerite from galena. In a certain number of cases, oiling reagents have been found which act differentially upon different flotable minerals, but every particular case still requires extensive research which does not always lead to a satisfactory industrial solution. Recently, an attempt has been made to recover coal from the waste heaps of collieries by means of flotation plant; technically entire success has been attained, since coal can be readily floated. Whether commercial success can be attained is another question, since the cost of fine grinding is a serious matter where a mineral of relatively low value is to be recovered. There is the further doubt whether coal which has been exposed to the weather, resulting in a dulling of its surface, can be made to float.

*Smelting.*—Beyond its immensely important direct effects in rendering possible the economic concentration of a number of ores and in cheapening the concentration of others, the development of flotation has also profoundly affected smelting practice, since the product of flotation, being very finely divided and wet, differs widely from the drier product of gravity concentration. The concomitant progress of the reverberatory furnace, to which reference has already been made, has been accompanied by another development which, although to a large extent independent, has also received indirect stimulus from flotation. This is the use of powdered coal as fuel, a development which is still in active progress and shows promise of very wide extension. Extremely finely divided coal is blown or otherwise forced into the actual combustion-space of the furnace, where it burns with a flame very similar to that of a jet of gas. The obvious advantages of such a system are that the loss of heat involved in the gasification of coal in producers is saved, together with the labour and the technical difficulties involved, while most of the advantages of gas-firing can also be secured by burning powdered coal. As against this must be set the cost of grinding the coal sufficiently fine and of injecting it into the furnace, while disadvantages also attach to the fact that the ash of the coal is introduced into the furnace and thence into flues, regenerators, etc. The question of the manner in which the coal is to be powdered and conveyed into the furnace receives rather different treatment in different forms of the process, but it is coming to be recognized that extremely fine grinding is advantageous and in one process the coal is made into an "emulsion" of coal-dust and air which is said to flow and to be capable of being pumped like a dense liquid. The coal particles appear to become coated with a closely adherent (probably "absorbed") layer of air and as soon as the temperature becomes high enough for ignition to occur, very rapid combustion takes place. The use of coal-air mixtures or "emulsions," however, implies the introduction into the furnace of a relatively large amount of cold air and this materially affects the question of regeneration or recuperation of the heat of the waste gases of the furnace. This is also affected by the presence of the fine ash-dust which tends to clog or even to flux the tubes or chequer-work. In some furnaces, where an extremely high temperature is not required, the problem can be solved by dispensing with regeneration or recuperation entirely and utilizing the heat of the waste gases for raising steam, etc. Another point to be borne in mind is that a suspension of coal-dust in air may be a powerful explosive and must be treated with the care due to such substances.

In the methods for the extraction of non-ferrous metals, during the period under review, there has also been an important development in an entirely different direction. This is the very great advance in hydro-metallurgical processes, such as leaching and direct electrolytic treatment of ores. The elimination of the German zinc smelters during the war, so far as supplies of zinc ores from the British Empire and the Allied countries were concerned, undoubtedly supplied a stimulus to this development, which has been particularly marked in connexion with the extraction of zinc from its ores. But the treatment of many other ores has also come within reach of "wet way" methods, and these undoubtedly promise to play an increasingly prominent part in metallurgical extraction in the near future.

*Organization.*—Among the factors of metallurgical progress, mention must be made of certain institutions and organizations which now play an important and growing part, particularly in regard to non-ferrous metals. The Imperial Mineral Resources Bureau, constituted in London towards the end of the war, and working by means of a large number of committees, assisted by all the leading metallurgists, serves to compile and publish a large amount of information, mainly in regard to the mineral resources of the British Empire, but dealing also in rather less detail with the resources of other countries. The continued progress and growth of the Institute of Metals has been a very marked feature of metallurgical activity; this body has now attained a membership of over 1,300, and issues two annual volumes of its "Journal," which constitute sources of standard reference and information. In America, an Institute of Metals has been formed on slightly different lines, as part of the Institution of Mining and Metallurgical Engineers. The British Engineering Standards Assn., formerly the Engineering Standards Committee, has also come to exert a powerful influence on the metallurgy of those metals which form the primary materials of engineering. The issue of standard specifications for a large number of non-ferrous metals has been undertaken, mainly for air-craft purposes, while recently the formation of a new Sectional Committee on Non-Ferrous Metals promises a further series of more general specifications. Further, in connexion with the British Government Department of Scientific and Industrial Research, a Non-Ferrous Metals Research Assn. has been formed and has begun to initiate important researches, particularly in connexion with copper.

*Copper.*—The effect of flotation, powdered-coal firing, and the advance of hydro-metallurgical methods on the metallurgy of copper, have already been mentioned. In regard to the metal itself, there is an increasing tendency for the exclusive employment of electrolytic copper. In part, this arises from the increased supplies of this quality of metal, but more from the increasing demand for high purity. "Best selected" and "tough" (arsenical) copper are still in demand for some purposes, particularly for locomotive fireboxes and stays; but there is considerable doubt as to the value of the arsenic, particularly as more complete de-oxidization of the copper is now practicable. For this purpose, particularly in connexion with the production of sound castings in high-conductivity copper, various agents have been advocated and employed. Crystalline Boron, and a substance known as "Boron sub-oxide," have been advocated and some success has been attained by their use. With regard to finished copper, much attention has been paid to certain anomalies which occur during severe cold-working, such as wire-drawing, while the effect of heating the metal in a reducing atmosphere has also been further studied. A particularly interesting case of failure in copper when heated in a bath of fused sodium chloride has been studied by the Bureau of Standards, at Washington. This material became brittle and broke with a typical inter-crystalline fracture. It was shown that this arose from an electrolytic effect produced by the contact of the

copper with the iron containing-vessel in the presence of the fused electrolyte (Rawdon). Metallic sodium is formed in contact with the copper and appears to penetrate between the crystals of the metal. A case has also been described where molten solder (lead-tin) acted in a similar manner when in contact with a particular kind of brass, the so-called " manganese bronze " (Dickenson).

*Copper Alloys.*—With regard to copper alloys, some progress has been made in regard to the difficult question of nomenclature. A committee appointed by the Institute of Metals has issued a first nomenclature Report which begins by defining the old terms " brass" and " bronze." The former is defined as any alloy of copper with zinc, containing more than 50% of copper; if other elements besides zinc and copper are present, they are to be named as a prefix to the term " brass." Thus an alloy containing 2% tin, 28% zinc, and remainder copper would be termed a " tin brass." Bronze on the other hand is defined as implying an alloy of copper with tin, containing more than 50% of copper, with the same convention in regard to additional elements. Thus an alloy containing 10% tin, 2% zinc, and remainder copper would be called a " zinc bronze." An attempt is also made to systematize nomenclature of more complex alloys. In the course of six or seven years this nomenclature, so far as brass and bronze are concerned, has made considerable headway, and these two terms are now rarely used except within the definitions named. On the other hand, the alloy formerly known as " German silver " and now generally, but quite misleadingly, named " nickel silver," should, under systematic nomenclature, be called " nickel brass," but there is some trade prejudice against the use of such a name.

An immense amount of experiment and research has been devoted to copper alloys, but the results cannot be adequately summarized in a few lines. A considerable number of special alloys are now known, each possessing valuable properties for various purposes. The aluminium manganese copper alloys have been very fully studied and described in the Ninth Report to the Alloys Research Committee of the Institution of Mechanical Engineers; these include alloys capable of attaining tensile strengths as high as 52 tons per sq. inch. Other alloys of special strength have been launched under various proprietary names, such as " Rubel bronze " and " Turbadium." For war purposes a most important part was played by the cupro-nickel alloys, containing either 15 or 20 % of nickel, remainder copper. The production of this alloy on the very large scale required for the war, revealed considerable difficulties in its production, arising mainly from casting-defects in the slabs used for rolling. The remarkable power of this material to undergo extremely severe cold-working, without becoming excessively brittle, suggests that it is likely to have other useful applications beside bullet envelopes, but for industrial purposes these alloys have not yet been widely exploited. On the other hand, the much more expensive Monel metal has been widely pushed and has found considerable practical application, mainly on account of the valuable combination of great strength with great power of resisting corrosion which it possesses. This alloy is manufactured " direct " by the reduction of ores from the Sudbury district in Canada, and special virtue is claimed on the ground that it is a " natural " alloy and has not been melted together in the foundry. It is more than doubtful whether such a claim can be in any way substantiated.

*Corrosion.*—In connexion mainly with copper alloys, a very large amount of study has been devoted to the subject of corrosion, under the auspices of the Corrosion Research Committee of the Institute of Metals. The results have been embodied in five extensive Reports to that body, and serve to throw a large amount of new light on the corrosion, particularly, of marine condenser tubes. This is ascribed, essentially, to the formation on the surfaces of the tubes of an adherent, but by no means impervious, deposit of basic salts. By restricting the circulation of water in contact with the metal under these deposits, they lead to the formation of solutions containing a fairly high concentration of cupric chloride, and such a solution rapidly attacks brass, with the resulting formation of pits and ultimately of holes. It is considered that the brass as a whole is dissolved under these deposits, but that in certain conditions the copper is redeposited as a spongy mass, thus leading to the apparent " dezincification " of the brass at such points. The prevention of this, the most destructive type of corrosion, thus becomes a question of preventing the formation of such adherent deposits, and several devices for this purpose have been suggested. The latest proposal is to coat the interior surfaces of the condenser tubes with a thin layer of metallic lead. Recently, the scope of the researches undertaken by the above-mentioned committee has been extended to include fresh-water (land) condenser plant, and a special sub-committee has been formed to study the whole question of the corrosion of aluminium alloys. Results of these inquiries and of a parallel investigation into atmospheric corrosion, undertaken by the Non-ferrous Metals Research Assn., are not yet available.

*Platinum, Etc.*—The metallurgy of the noble metals has not undergone any very striking development during the period under review, either in regard to extraction or uses. The cyaniding process has undergone a series of more or less minor improvements, and it was at one time thought that aluminium dust would replace zinc-dust as the precipitant for pregnant solutions. Although aluminium is used to some extent, zinc-dust still predominates and the same remark applies to the proposed method of precipitating the metal electrolytically. In regard to platinum, there has been an ever-increasing scarcity, enhanced by the complete upheaval in Russia. The great rise in the price of platinum has naturally led to the study of possible substitutes for various purposes, and a number of such materials have been put forward. Thus for the " breaks " used in the magnetos of internal combustion engines, tungsten sparking points have been substituted for platinum with great success. For chemical purposes various alloys, some containing gold and palladium, have been tried, but only with partial success, since none of them really possess the combination of properties—chemical resistance and very high melting point—which renders platinum so valuable. A number of special alloys, in which tungsten and chromium generally play an important part, also exhibit great chemical resistance, but in these cases the hardness and brittleness of the material are generally a serious difficulty. For use in chemical work on a large scale, however, a considerable number of alloys have been produced which attain a fair measure of success. Silicon itself has many advantages for some of these purposes, but in the impure form, generally met with, it is relatively weak and brittle.

*Zinc.*—The metallurgy of zinc received much anxious attention during the war period. Reference has been made above to the general questions relating to zinc extraction, but the use of the metal and its alloys also received attention. On the Allied side there was at one time considerable shortage of zinc, and substitute alloys were studied for all purposes which should avoid the use of zinc. The shortage then disappeared, and at a later stage alloys consisting mainly of zinc were tried as substitutes for brass and for certain aluminium alloys. Some of these zinc alloys proved to possess remarkable properties, tensile strength exceeding 20 tons per square inch being obtained in cast alloys containing about 3% of copper and 7% of aluminium, remainder zinc. It was further found that these alloys could be extruded and, under certain conditions, rolled. In the severely rolled state they show remarkable ductility when slowly loaded, but are entirely brittle if the stress is applied rapidly; if annealed—even by quite moderate warming—they revert to the strength and entire non-ductility of the cast material. Unfortunately it has been found that alloys of this type, when they contain both aluminium and copper, are unstable and undergo serious changes of volume, accompanied by great loss of strength, even at the ordinary temperature if kept for any considerable time, such as a year. None the less, a considerable number of shell-fuses were successfully made of such an alloy, but they were used before dangerous deterioration had set in. It is interesting to note that on the German side, while there was never any shortage of zinc, this metal and its alloys were extensively employed as substitutes for other metals. Pure zinc was widely used in place of copper for electrical purposes, while zinc alloys with copper and aluminium were also largely used. Apparently, cases of failure due to the instability of these materials passed unnoticed under the stress of war; at all events, German metallurgists have described these " war bronzes," without mention of such deterioration with time, except as the result of corrosion. It may be mentioned, however, that alloys rich in zinc, which contain either copper alone or aluminium alone, appear to be free from the trouble in question (Rosenhain, Haughton and Bingham).

*Aluminium.*—Aluminium and its alloys have played a particularly conspicuous part and have undergone remarkable developments during recent years. Prior to the outbreak of war, aluminium itself had become relatively very cheap (below £100 per ton), and this fact stimulated interest in its use. During the war, on the other hand, while the metal itself became scarce and very dear, its applications for military purposes grew enormously in importance and raised its alloys for the first time to the rank of important materials of engineering construction. Its uses arose mainly in connection with air-craft and became increasingly important in the closing years of the war. It must, of course, be recognized that this rapid development of aluminium alloys under war conditions was to a considerable extent the result of progress which had been made prior to 1914. One step in this progress was marked by the section on light alloys contained in the Ninth Report to the Alloys Research Committee (Rosenhain and Lantsberry), published in 1909; but the discovery, by Wilm of Berlin, of the possibility of hardening aluminium and its alloys, when a small percentage of magnesium had been added to them, led to the next and very important forward step. The application of this discovery to the best of the alloys, described in the above-named Report, led to the production of the now widely known and used alloy " duralumin." This contains from 3 to 5% of copper, about 1% of manganese and about 0·5% of magnesium. As rolled, this material has a tensile strength of about 18 tons per square inch, but if heated to a temperature of 480° C. to 500° C. and quenched, it gradually acquires much greater strength—rising to about 26 tons per square inch; the ductility remaining the same at about 16 to 18% elongation on 2 inches. There can be no doubt that such a material, possessing the strength of a very mild steel combined with a density as low as 2·8, constituted a remarkable advance in wrought aluminium alloys. At quite an early stage in its history this alloy was employed for the construction of Zeppelin airships. The manufacture of the alloys was taken up in England under licence from the German patentee, and the alloy has been extensively used in the construction of British rigid airships. Its use has, however, not been free from difficulties and disadvantages, and great efforts have been made to

arrive at better alloys by research in this country. As a result, a series of new aluminium alloys for use in the wrought form have been developed, mainly as the result of extensive researches at the National Physical Laboratory. In the first place, a series of alloys containing from 18 to 20 % of zinc were produced. These were of a type which had up to that time been regarded as incapable of being rolled or forged, but the initial difficulties of that kind were overcome by a careful study of their properties both in the foundry and the rolling-mill. The result was the production of an alloy containing 20 % of zinc and 3 % of copper, generally known as "3–20" or "Alloy A." This shows a tensile strength, in the condition as rolled, of 27 to 28 tons per square inch with an elongation of 18 to 20 % on 2 inches. It is thus a little stronger than duralumin, but also a little heavier (its density is about 3·1). It is simpler to make and use than duralumin, as it requires no special heat-treatment, and it is—unlike duralumin—not liable to be seriously weakened by a slight amount of annealing. On the other hand, this alloy is liable to be damaged in other ways if heated much above 250° C., and it loses its strength very rapidly with rising temperature, at all events above 100° C., while it is also distinctly less resistant to corrosion than duralumin. For many purposes, however, where cheapness and simplicity of treatment are important, and where the material is not exposed to severely corrosive conditions, the "Alloy A" (3–20) possesses distinct merits. This alloy has, however, been considerably improved upon by a series of alloys in which both manganese and magnesium have been added to the simple aluminium-zinc alloy. These require quenching and ageing, but after such treatment can be made to attain a tensile strength of 40 tons per square inch. They are, thus, in regard to strength for a given weight, considerably superior to duralumin and this relative value is particularly apparent under compression (buckling) tests. On the other hand, these alloys require careful protection from corrosion and their heat-treatment must be carefully carried out. Another very important group of "wrought" alloys are those containing nickel and magnesium in addition to copper. The most important of these is one developed at the National Physical Laboratory and known as "Alloy Y," or "4–2–1½," the latter figures representing the composition: copper 4 %, nickel 2 %, and magnesium 1½ %. This alloy, when quenched from a temperature of 530° C. after previous cold-rolling, can be made to attain a tensile strength of 28 tons per square inch combined with an elongation of 20 % on 2 inches; its density is 2.8, and it possesses two very important further properties, viz. remarkable resistance to corrosion, and a relatively very high resistance to fatigue (repetition stresses), particularly at slightly elevated temperatures. Forgings of this alloy have been successfully used as connecting-rods in high-speed internal combustion engines, and there is every reason to anticipate a constantly widening range of engineering uses.

Promising and important as are the results achieved with the wrought alloys just described, results of more immediate importance were achieved with casting alloys of aluminium. At first these were employed mainly on more or less subsidiary castings, such as crank-cases, and for that purpose an alloy containing from 12 to 14 % of zinc and about 2½ % of copper (generally known by the number of the British Air-board Specification as "L5") was very widely used. Efforts were soon made, however, to employ light-alloy castings for more important parts in aeroplane machines, viz. cylinders and pistons. Here the value of these materials lies not so much in their specific lightness as in their high thermal conductivity. In the case of the cylinder castings of air-cooled engines particularly, this is valuable in preventing distortion arising from unequal cooling of the windward and leeward sides, while in the pistons it reduces the temperature of the compression space and thus increases the density of the indrawn charge, and at the same time allows of the employment of higher compression ratios. The effect of these advantages is to increase the power output of an engine of given size and weight very appreciably, while also reducing the petrol consumption. The alloys first and most extensively used were those of aluminium with copper, a 12 % alloy being particularly popular. Another widely used alloy contains 7 % of copper with 1 % of zinc and 1 % of tin, but it is now recognized that the presence of tin renders the alloy weak under shock when hot. These alloys, although initially not as strong as some of those containing zinc, do not lose their strength so rapidly when heated, so that at the working temperature of an aluminium-alloy piston (about 250° C.) they are stronger than such an alloy as "L5." Even these alloys, however, are relatively very weak when hot—they register a tensile strength of about 6 to 7 tons per square inch at 250° Centigrade. Recently, researches at the National Physical Laboratory have shown that the alloy already referred to above as "Y"—containing copper 4 %, nickel 2 %, magnesium 1½ % is particularly strong at high temperatures, even in the cast state. It is, further, amenable to hardening by quenching and ageing even in the form of castings, and when thus treated attains a tensile strength as high as 20 tons per square inch at the ordinary temperature and 13 tons per square inch at 250° Centigrade. This alloy is rapidly finding its way into extensive use and many important applications are being opened up as the result of its remarkable properties.

*Cobalt and Lead.*—Developments in the remaining metals are mostly of a minor nature and cannot be referred to in detail. Mention should, however, be made of the progress made in connexion with cobalt. Its use in steel and in certain special alloys has already been mentioned, but it has also been shown to give a more adherent and more durable electro-plate coating than nickel, and it is important to note that its resemblance to nickel is not nearly so close as was previously supposed. In regard to lead and its alloys, a remarkable development has been that of alloys with the rare-earth metals, particularly calcium and barium. These confer a remarkable degree of hardness on lead, and a special alloy of this kind, known as "Ulco," is finding application as a bearing-metal. A substitute of this kind was called for as the result of the very high prices attained by tin under war conditions, but the permanent value of the materials has yet to be established.

PHYSICAL METALLURGY.—Side by side with, and to a great extent furnishing the basis for, the development in the treatment and use of metals and their alloys, there has been a very great and important development of metallurgical science, particularly in the direction of what has been called "Physical Metallurgy." The mass of work which has been published on this subject is so great that even an approximately exhaustive bibliography would occupy more than the space available. Only a few outstanding features of the progress achieved can therefore be briefly mentioned.

A very large amount of work has been devoted to the further and more detailed study of the constitution of alloy systems. Although somewhat rough preliminary determination as of the equilibrium diagrams of most binary alloy systems had been previously made, a number of these have been revised and rendered more accurate. In ferrous alloys, the iron-carbon system has received much further study, particularly in regard to the critical points of iron itself. Important work at the Bureau of Standards, U.S.A. (Burgess and Crowe), has firmly established the three well-known critical points, $A_1$, $A_2$, and $A_3$, and has shown that previous attempts on the one hand to discredit the very existence of $A_2$ (Carpenter) and on the other to show that it was a double point (Arnold), were based on experimental error. On the other hand, German investigators (Ruer, Hanemann) have established the existence of a higher critical point, which in pure iron occurs at a temperature very close to 1,400° Centigrade. In connexion with the critical points, considerable attention has been devoted to the whole question of allotropy. A Dutch school of investigators (Cohen) have sought to show the existence of numerous allotropic transformations in many metals, but their conclusions are based on extremely slight evidence derived from determinations of minute irregularities in density changes. On the other hand, the Japanese school (Honda) seek to show that the $A_3$ transformation in iron is not allotropic in character and this view is confirmed, to a certain extent, by strong evidence that the passage through this point does not involve any change of crystallization—evidence which has recently been confirmed by the X-ray analysis of the crystal structure of iron and steel at various temperatures (Westgren). The matter, however, rests entirely upon the precise definition of allotropy which is adopted. In addition to the iron-carbon system, the iron-nickel, iron-chromium, the manganese-carbon and nickel-carbon systems have been carefully investigated. No attempt, however, appears as yet to have been made to attack the detailed study of the equilibria of such important ternary systems as iron-nickel-carbon, iron-manganese-carbon or iron-nickel-chromium, no doubt on account of the length and difficulty of such an investigation. In non-ferrous alloys, considerable attention has been given to the alloys of zinc, a portion of the ternary system copper-aluminium-zinc (alloys rich in zinc) having been very fully worked out (Haughton, Bingham). The allotropy of zinc itself has also been very thoroughly studied (Benedicks, Bingham) and the reality of the transformations well established. Great advances have been made in the knowledge of the equilibria of several of the important alloy systems in which aluminium is the predominant metal. The ternary systems aluminium-zinc-copper, aluminium-iron-silicon and aluminium-magnesium-silicon (Hanson, Gayler) have been very fully worked out so far as the alloys rich in aluminium are concerned. For the representation of the results of such investigations a new type of model has been devised (Rosenhain), in which the various equilibrium surfaces are represented by systems of wires coloured to indicate the phases concerned in each transformation. The study of the aluminium-magnesium-silicon system has proved particularly important, owing to the light which it throws on the age-hardening properties, which are found in many aluminium alloys containing magnesium. It has been shown that the magnesium in these alloys is present as a definite compound $Mg_2Si$, which is more soluble in solid aluminium at high temperatures than at the ordinary temperature. Quenching such an alloy from a temperature just below its solidus retains the compound in solid solution and in this state the alloy is soft. Gradually, however, at the ordinary temperature, and more rapidly at slightly higher temperatures, this super-saturated solid solution deposits the excess of dissolved compound in an extremely finely divided condition and this process is accompanied by gradual hardening of the alloy. This process is strictly analogous to that which can be brought about in certain alloy steels which can be rendered (or kept) completely "austenitic" (homogeneous solid solution) by quenching; they are then soft and ductile, and do not

undergo hardening while at rest at the ordinary temperature. If the temperature is raised so as to bring about "tempering," the solid solution breaks down in precisely the same way as indicated above and the steel becomes hard (and also magnetic). It would thus seem that hardening as the result—direct or indirect—of quenching is due to the separation from solid solution, in a state of extremely fine division, of a phase the formation of which had been suppressed by quenching. According to the theory of amorphous metal (see below) each of the minute crystallites of the phase thus separated will be surrounded by a zone of amorphous metal, which is itself very hard. If the minute crystals thus separated are sufficiently small and numerous, the result will be that a considerable proportion of the whole alloy will be thrown into the amorphous state, extreme hardness resulting. On this view, the martensite of hardened steel should consist mainly of minute crystallites of alpha-iron embedded in an amorphous matrix consisting of iron and carbon (or carbide) in solution in it. This suggested constitution of martensite readily accounts for its hardness and for the fact that it is magnetic, and—in view of the intimate manner in which the minute crystallites of alpha-iron are embedded in unyielding and un-magnetisable amorphous metal—for the magnetic hardness of the martensitic steel. This view is further confirmed by the observation that the chemical behaviour of quench-hardened steel is in certain respects closely similar to that of the same steel hardened by cold work and thus rendered partially amorphous (Whiteley). Finally, it has recently been shown by X-ray methods, that the space-lattice typical of alpha-iron is present in martensitic steel (Westgren).

The theory of amorphous metal, just mentioned, has played a very important part in scientific metallurgical thought during the period under review. The conception that metal could be rendered amorphous by mechanical disturbance of its crystalline structure was originated by Beilby, in the first instance, to account for the phenomena observed by him and others in connexion with the polishing of metals and other substances. Beilby further applied the conception to explain the hardening which metals undergo as the result of plastic deformation (cold work) by suggesting that layers of amorphous metal are formed on the surfaces of internal slip which occurs during plastic straining. Both these theories are now widely, if not universally, accepted in England and America, but still find opposition on the Continent, where the weight of the experimental data is not sufficiently appreciated. More recently Rosenhain has brought forward a conception which has already been present in the minds of many other investigators (notably Osmond) in a less definite form, that a film or thin layer of amorphous metal exists in the inter-crystalline boundaries of all metals, quite apart from any effects of strain. This view has been vigorously contested, but experimental evidence in its confirmation has been steadily accumulated from a very great variety of sources, until at the present time the "intercrystalline amorphous cement" theory is at least as firmly established as that of the "amorphous theory of strain-hardening." The most striking series of facts supporting the "amorphous cement" theory is connected with the behaviour of the inter-crystalline boundaries under stress. It is well established that in normal circumstances these boundaries are stronger than the crystals themselves, so that fractures of metals generally occur by breaking through the crystals and not by pulling them apart. It has, however, been shown that at a high temperature near to, but definitely below, the melting point, pure metals can be easily caused to break with a perfectly inter-crystalline fracture (Rosenhain and Ewen). This is to be ascribed to the greatly decreased viscosity at such temperatures of the inter-crystalline amorphous metal, which is regarded as possessing the properties of a viscous under-cooled liquid. The actual viscosity, however, depends very much upon the nature of the metal and upon the temperature—the farther a metal is below its normal melting-point the higher the viscosity of the amorphous phase. Accordingly, in some of the softer metals and alloys the amorphous material is sufficiently mobile to allow of sensible movement in relatively short times. Thus, an alloy of zinc with copper and aluminium has been discovered which, in the cold-worked state when it is partially amorphous, behaves very much like pitch; it will bend to any desired extent if allowed to do so gradually, but breaks short if rapid bending is attempted. Similarly, the inter-crystalline cement in certain metals and alloys, although it proves stronger than the crystals when the metal is loaded at any normal rate, appears to be capable of giving way by some form of viscous or visco-elastic movement under very prolonged loading such as that due to internal stresses. Much attention has been devoted to the study of fractures occurring in various metals as the result of the application of internal or other prolonged stresses. In brass these phenomena have become known by the misleading term "season cracking," but it has recently been discovered that strikingly similar phenomena are to be found in a number of other metals, including lead, certain alloys of aluminium, platinum and steel (Rosenhain and Archbutt). It has been shown that in the case of brass, lead, steel and aluminium alloys, certain types of chemical reagents which appear to act preferentially upon the material in the crystal boundaries, contribute to the occurrence of such fractures, which are typically inter-crystalline (Moore and Beckinsale). At the same time it has been clearly shown that in the case of the aluminium alloys at all events such chemical action serves to accelerate the fractures, but is not essential to it, since it occurs, although more slowly, in high vacuum or in an atmosphere of pure dry hydrogen (Rosenhain and Archbutt). In the case of brass it seems probable, although it has not yet been finally demonstrated that "season cracking" can occur without the intervention of any chemical action. Similar types of cracking which have been discovered in mild steel, however, appear to be very closely associated with the effects of certain chemicals, such as concentrated solutions of alkalies, fused ammonium nitrate, etc. While there are still some metallurgists who refuse to think in terms of an amorphous inter-crystalline cement (Hatfield, Tammann), the great majority of investigators are agreed that, directly or indirectly, this conception serves to explain the occurrence not only of inter-crystalline fractures under prolonged loading but also a number of other phenomena associated with the crystal boundaries.

Intimately connected, also, with the nature of inter-crystalline boundaries is the whole of the important phenomena of re-crystallization and crystal growth which are of such fundamental importance with all annealing and heat-treatment operations. These have been studied in great detail in recent years. One of the most striking features is the relatively rapid formation of large crystals in certain conditions. Thus in an oblong piece of metal which has been severely strained, and is then heated in such a way as to be well above the usual temperature of re-crystallization at one end and well below it at the other, a zone is found in which very large crystals are formed; this may occur either as the result of a temperature-gradient being applied to a uniformly strained piece of metal or of the application of a suitable uniform temperature to a piece of metal in which there is a strain-gradient. The explanation appears to be that for a given degree of previous plastic strain there is a temperature most favourable to rapid crystal growth (Jeffries). An interesting practical application of the ideas derived from the study of these phenomena is the production of wires of certain metals, notably tungsten, which have been so treated as to consist, for considerable lengths, of single long crystals. This result is achieved by drawing the cold-worked wire into an annealing furnace at a suitable temperature at precisely the right rate. The tungsten wire thus produced is particularly valuable for the manufacture of electric lamp filaments and it has also been shown to possess interesting elastic properties (Wartenberg), which are readily accounted for by the absence in such material of any amorphous inter-crystalline material the viscous or visco-elastic properties of which affect the behaviour of the wire in this respect. Much study has also been devoted particularly to the re-crystallization of aluminium after cold-working, but new theoretical views have not yet been advanced. Here, as in almost every direction, the progress of research upon metals and alloys tends to open up new avenues for further research and further advance. In a subject which is showing such rapid and vigorous growth, such a summary as that here given cannot hope to deal with more than a few outstanding points which appear to be of primary importance, but development is so rapid and on such wide lines that it is impossible to foresee what trend it may follow in the near future.

LITERATURE.—For iron and steel metallurgy, industrial as well as scientific, the journal of the *Iron and Steel Institute* should be consulted, not only for original publications but for abstracts which cover the literature of the whole world on this subject. In addition, excellent abstracts will also be found in the metallurgical section of the journal of the *Society of Chemical Industry*, while such journals as *Stahl und Eisen*, the *Revue de Métallurgie* and *Chemical and Metallurgical Engineering* also deal with this branch of the subject. In addition to *Iron Age*, *The Iron and Coal Trade Review* and similar journals may also be mentioned, but adequate references to these can be found in the abstracting journals already mentioned. As regards general metallurgy, the annual volumes of *Mineral Industry* contain detailed reviews of progress, year by year, while the journal of the *Institution of Mining and Metallurgy* contains important original papers. For the non-ferrous metals, apart from their reduction from the ore, the most valuable reference is to the journal of the *Institute of Metals*, including particularly extensive abstracts as well as original papers. The *Revue de Métallurgie* and several German journals, also formerly the *International Journal of Metallography* (now *Métallographie*), may be named, as well as the appropriate section of the *American Institution of Mining and Metallurgical Engineers* (American Institute of Metals). The publications of the Bureau of Standards (Washington, U.S.A.) and of the National Physical Laboratory (Teddington, England) are also of first-rate importance. The Faraday Society (London) has also published in its *Transactions* several "General Discussions" relating to metallurgical subjects, including particularly one on *The Failure of Metals under Internal and Prolonged Stress*, another relating to metallurgical microscopy, and one on the application of X-rays. (W. RN.)

**METEOROLOGY** (*see* 18.264*).—Since 1910 considerable advances in meteorological knowledge have been made both on the observational and the theoretical sides. The World War emphasized the importance of meteorology, more particularly in regard to a knowledge of the density and of both the direction and velocity of the wind in the overlying air strata, and the meteorological services of the combatant nations were largely

**These figures indicate the volume and page number of the previous article.*

extended to obtain the information and disseminate it rapidly to their own troops. But while the war acted as a stimulus to the obtaining of data about the regions in which aircraft of all kinds are used and through which projectiles pass, in another way it has been a great hindrance to an advance in meteorological science. Not only were the international committees largely broken up but in the latter stages of the war the publication of observations was prohibited; each nation treated its own work as more or less confidential, and although all restrictions are now removed it is not easy to obtain and assimilate the important papers that were written during the war.

*The Upper Atmosphere.*—During the years before the war observations on the temperature and humidity of the air strata were rapidly accumulating, more particularly from a network of stations spread over Europe, and since the W. and N. of Europe is subject during the winter to the passage of many deep cyclonic depressions, the conditions of temperature in cyclones and anticyclones up to a height of some 20 km. (12½ m.) had become known. The brief tables which were all that were available to Cleveland Abbe in 1909 had been supplemented by much information, drawn up and arranged for the European results by Lt.-Col. E. Gold (M.O. No. 210e, *Geophysical Memoirs*, No. 5), by Dr. Wegener for the Continent (*Die Temperaturverhältnisse in der freien Atmosphäre*, III. Band, Heft 2/3, Leipsic, 1909) and for Russia by Dr. Rykatchew (*Meteorologische Zeitschrift*, Jan. 1911). In 1916 a summary of the information available about the upper air was drawn up for the Meteorological Office but not published. It quoted freely from Gold's paper but included the results of observations up to 1916. This summary together with certain theoretical matter was published in 1919 under the title "Characteristics of the Free Atmosphere" (M.O. 220c, *Geophysical Memoirs*, No. 13), and from it the following abstract summarizing our present knowledge of the strata from 0 to 20 km. is mostly taken.

*Temperature.*—As the surface of the earth is left the temperature of the air decreases with increasing height, and when the great variations of climate and of the conditions prevalent in different parts of the earth are considered it is remarkable how uniform is the fall of temperature, now commonly called the lapse rate. The height to which it extends is variable, but in all places in which observations have been made, the lapse rate up to 8 km. has been found close to 6° C. per kilometre. This holds, not indeed exactly but approximately, for summer and winter and for places as far apart as the equator and Ross Bay in lat. 78° S. Thus in Batavia the lapse rate up to 8 km. is 6·1° per km.; at Petrograd it is 5·8°. In England in the winter it is 5·8°, in the summer it is 6·0°. These are means but the rule holds quite well even for the individual case, for if in one part of the 8 km. the lapse rate is small this is usually compensated for by its being large in the other part. The only important exception that has been found so far is in regions and at times where the temperature is extremely low, as in Siberia or Canada in the winter. In such instances the bottom layer is unduly cold and the lapse rate is negative over the first 2 km., so that the rule would make the upper air temperature too low. Also it must be remembered that the daily variation of temperature does not extend upward more than one or two km., so that the mean for the day rather than the precise temperature at the moment should represent the surface temperature. This layer, in which temperature falls with increasing height, is called the *troposphere*.

At a certain height, which varies with the latitude, with the barometric conditions and with the season, the fall of temperature ceases, and the air up to the greatest heights that have been explored remains at a nearly uniform temperature in the vertical direction. This upper part in which there is no lapse rate is called the *stratosphere*. The boundary between the two parts is found at about 16 km. near the equator and at 10 km. in northern Europe. Over England its mean height is 10·5 km., falling to rather below 10 km. in the winter, and rising to over 11 km. in the summer. In the centre of a deep cyclone the value may easily fall to 8 km.; in an anticyclone it may exceed 12 km.

The temperature of the stratosphere is below 200° A. over the equator and in tropical regions; it is above 220° A. in northern Europe. In Canada it seems to be lower in the summer than in the winter. These anomalies are roughly expressed by the rule that the mean temperature of the air column taken with regard to height from 0 up to 19 km. is approximately the same in all parts of the earth. There is probably a physical reason for this, and it explains the unexpectedly low temperature above 14 km. over the equator and the curious reversion of temperature between summer and winter over Canada (Toronto) where the seasonal range is very large.

The annual range of temperature in the troposphere does not differ very greatly from the range at the surface; in island and coastal climates like England it is rather greater in the upper parts than at the surface; in continental climates the surface has the greatest range. In the stratosphere the range is much reduced and, as already stated, appears in Canada to be reversed although enough observations are not yet available to make this absolutely certain.

Whether or not there is any regular diurnal change of temperature above 2 km. height is uncertain; all that can be said is that if there be any its amplitude is certainly less than 1° C.

The mean annual temperatures are given in the accompanying Table I. In Europe the probable error of any value is about 1° C.; for Canada and the equator owing to paucity of observations it is greater, especially above 15 km., where it may reach perhaps 3° C. Over Europe the mean temperature does not change from 14 to 20 km. and does not change much over Toronto. Over the equator the lowest temperature, which is about 193° A., is not reached under 16 or 17 kilometres.

TABLE I.—*Mean Temperature.*

The values are in the Absolute scale with the first "2" omitted. 273·0° = 0° C. = 32° F.

*Pressure and Density.*—The temperature of the air having been found by observation, the pressure and the density are easily found up to the height to which the observations extend. In the same way the mean pressures and mean densities can be determined from the mean temperatures without appreciable error provided the mean pressure at the surface is known.

In the lower strata the pressure at any particular height is naturally most dependent upon the surface pressure, but since the air is lighter, bulk for bulk, when it is warm the pressure decreases less rapidly than usual in a warm area, and the pressure at any given height depends more and more upon the temperature of the underlying air as that height increases. Thus it comes to pass that in the hot regions of the earth, say in the belt included between the two tropics, the pressure at the height of 9 km. is very much less than it is at the same height over temperate latitudes, and the pressure gradient which causes the prevailing westerly winds of the cirrus level is thus produced. At a height of 20 km. the surface pressure has ceased to have much effect, and it requires a rise of nearly 20 mb.[1] in the surface pressure to produce a rise of 1 mb. at 20 km., whereas a change of 1·5° C. in the temperature of the air column will produce that effect. It has been stated that the mean temperature of the air column up to 19 km. is much the same in all parts of the world, and it follows that the same level is one of nearly uniform pressure.

The pressures are given in Table II. at various stations for heights up to 20 kilometres. The values for Canada and the equator at heights above 15 km. are not very reliable owing to paucity of data.

The densities are given in Table III. The variations in the density became of great consequence during the war on account of their influence on the range of projectiles; they depend on the connexion which has been found to exist between temperature and pressure.

*Statistical Methods.*—Statistical methods have been much in vogue of late years and it is necessary to indicate how the method of correlation has been used for forecasting and for elucidating meteorological problems. A large number of correlation coefficients have been determined between various meteorological events, and the values of many of them are given in the *Computer's Handbook*, M. O. 223, Section V, Tables, published by the Meteorological Office.

The advantage of a correlation coefficient in estimating the connexion if any between two events is that it expresses the connexion as a decimal which must lie between 1 and −1, and

[1] The average pressure of the atmosphere at sea-level being reckoned as 1 bar, = 1,000 millibars (mb.). 1 mb. = 0·0295306 mercury in. at 32° F. in lat. 45°.

thus renders the connexions between different pairs of events comparable with each other. The velocity of the wind and the steepness of the barometric gradient may be taken as an example. The actual connexion is obvious from the daily weather charts; on some it is well marked, on others badly, but the fact that there is a connexion is quite apparent from even two or three charts. The correlation coefficient is about ·70.

The application of the method of correlation to forecasting can hardly be looked upon as very successful. Two highly correlated events are required happening with a definite time interval between them. A correlation coefficient may be high accidentally if it be founded on too small a number of instances, but genuinely high coefficients between meteorological events occurring with more than a few days' interval betweem them are hard to find. The most successful instance is perhaps the forecast of the monsoon rain of India by G. T. Walker from the correlation between it and sundry other events occurring in the spring of the same year or earlier. In this case the correlation coefficients on which the forecast is based have values of about ·50; if values of ·80 or ·90 could be obtained very much greater success would be secured. There are a few coefficients of from ·70 to ·80 between the rainfall at various periods and the subsequent yield of sundry crops. Thus in the eastern counties of England if April and May be wet it is a practical certainty that there will be a large hay crop, and if the autumn be dry there will almost certainly be a large crop of wheat the next year. Mr. R. H. Hooker has calculated a most interesting set of figures relating to the correlation between the weather and the crops. Similar work has been done for the potato crop in America by J. Warren Smith, and many correlation coefficients relating to agricultural matters are available from Sweden and elsewhere.

The case is different where correlation is resorted to for the purpose of elucidating some physical process in the atmosphere; here a small coefficient is just as likely to give information as a large one. But the interpretation of the meaning of the coefficient is often difficult, and in many cases the value obtained is quite different from that which most meteorologists would have expected.

G. T. Walker in addition to his statistical work on the monsoon rain has published several sets of correlation coefficients, and amongst them a set of 100 showing the correlation between the sunspot number and the temperature at 100 stations well distributed over the earth's surface. The correlation is negative and small but it is large enough to be significant and to prove that during the 40 or so odd years considered the temperature of the earth as a whole was lower at the time of the sunspot maxima than at the time of the minima. It is commonly supposed that the sun is giving out most energy when its surface is most disturbed, and this idea has been confirmed by direct observation of the radiant heat. A perfectly satisfactory explanation is at present wanting. Another case is the low correlation between the direction of the wind and the temperature of the lower air strata (see a paper by Capt. C. K. M. Douglas, *Q. J. Met. Soc.*, Jan. 1921, vol. xlvii., No. 197), a most unexpected result. Walker also correlated between sunspots and rainfall, and found the coefficient too small to be significant. However, in none of these cases has the work been wasted since important conclusions have been established.

For high correlation coefficients one must take data relating to the upper air. The relation between pressure and temperature is so remarkable and has such a close relationship to the theory of cyclones and anticyclones that it will be treated separately. The correlation coefficients between the thickness of the troposphere, a height commonly denoted by $H_o$, the surface pressure, the temperature of the stratosphere and other variables often exceed ·70, and the generally high values show quite plainly that there is an ordered sequence in the processes going on above, which is strikingly absent from the surface phenomena.

*Cyclones and Anticyclones.*—In the meteorological literature of the past no subject has been so much discussed or has had so much attention directed to it as the causes of cyclones and anticyclones. When it became possible to obtain observations of temperatures and humidity, and in clear weather of wind direction, from the upper air it was confidently hoped a solution would be found—a hope as yet unfulfilled. But the mass of information collected from Europe, more particularly from the northern and western parts where cyclones are frequent, has given a large amount of detailed information and we have a clear conception of what happens as a cyclone passes over. It is true that we have no simultaneous sets of observations, so that we cannot draw a chart of any one particular cyclone, but we have numerous observations showing the departures from the mean corresponding to any observed surface pressure and to any special section of the cyclone.

The facts that stand out are that in a cyclone the troposphere is cold and the stratosphere warm, in an anticyclone the reverse is the case; in a cyclone the tropopause is low, in an anticyclone high. Thus as an area of low pressure passes across the map the following changes occur in the various air strata above. The deficiency of pressure is about the same from the surface up to some 10 km., above which it falls off rapidly until the normal value for the height

TABLE IV.

*Correlation Between Pressure and Temperature*

| Height km. | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Jan.–March | − 02 | ·54 | ·82 | ·79 | ·86 | ·85 | ·84 | ·87 | ·91 | ·81 | ·35 | −·32 | −·38 | −·37 |
| April–June | 14 | ·28 | ·49 | ·79 | ·89 | ·89 | ·92 | ·87 | ·81 | ·45 | ·20 | −·12 | −·24 | −·01 |

| Oct.–Dec. | ·33 | ·56 | ·76 | ·77 | ·83 | ·87 | ·85 | ·85 | ·86 | ·78 | ·29 | −·24 | −·34 | −·50 |
| Means | ·11 | ·42 | ·66 | ·77 | ·84 | ·85 | ·86 | ·86 | ·86 | ·72 | ·32 | −·19 | −·36 | −·28 |

is reached at about 18–20 kilometres. The temperature from about 2 to 8 or 9 km. falls, and from 10 to 20 km. it rises. The height at which the lapse rate ceases, the limit of the troposphere falls. These statements are based on the very high correlation coefficients that are found to exist between pressure and temperature. It will be seen from the accompanying table (which gives the correlation coefficients) that close to the surface the correlation is low, but it is very high from 4 km. to 8 kilometres. In calculating these values the observational errors have not been allowed for, the correct values are most likely well over ·90. There are probably two reasons for this. The surface temperature is governed by many considerations—the time of day, the state of the sky, the strength and direction of the wind; higher up these disturbances do not apply, for, as has been already stated, the diurnal variation is very shallow and the correlation between the components of the wind and the temperature is surprisingly small above a few km. height. Secondly it may well be that the chief item in determining the temperature is the recent vertical motion of the air, and a systematic vertical flow of air either up or down is plainly impossible quite close to the surface. The rise and fall of the tropopause ($H_0$) and the regularity with which it occurs is shown by the high correlation, ·84, between it and the pressure at 9 km. height. There is hardly a single instance of observations made in Europe at a time of really low barometer in which $H_0$ has not been found well below its average value. The dependence of the temperature of the stratosphere on the barometric conditions is not so close, the correlation being only ·50; but based on some hundreds of observations as these correlation coefficients are, ·50 is amply significant. Still the importance of a correlation in general depends upon its square rather than upon itself, and the significance of ·50 is very different to that of ·90 or ·85.

One noticeable result of this high correlation between pressure and temperature is that the density is not subject to much variation save close to the surface, for a high pressure and a high temperature act upon the density in opposite ways and since they occur together the density remains comparatively unchanged.

*The Vertical Flux of Heat in the Atmosphere.*—A much clearer and more definite view of the passage of heat upwards and downwards in the atmosphere has been secured, and in no direction excepting perhaps that of our knowledge of the upper air has the advance of meteorological knowledge been greater. This desirable result is largely due to a paper by Major G. T. Taylor (*Phil. Trans.*, A., vol. ccxv., pp. 1–26), which formed the starting-point, and has been followed by other papers on the same subject by himself, by Mr. L. F. Richardson, by Dr. W. Schmidt (Vienna), and by others.

There are seemingly four methods by which an appreciable vertical flux of heat energy is produced in the atmosphere. (1) Convection, which carries heat upwards from the earth's surface; its action does not extend beyond the first few kilometres. (2) The latent heat set free by the condensation of aqueous vapour which carries upwards to the regions where clouds are formed the solar heat which has evaporated the water from the sea or wet land surface; this acts in just the same region as convection. (3) Radiation, which mostly carries heat upwards from a lower to a higher stratum. These three methods present no difficulty but it must be pointed out that "convection," as is usual in meteorological literature, means local convection, *i.e.* heat carried by an ascending current that is produced by local warmth, not heat carried by an air current or by eddy motion due to the general circulation.

The fourth method, which invariably brings heat downwards, is not so easy to understand but is no less genuine than the others. It has been given various names, "mixing," "stirring," "turbulence," and (from the German) "mass-interchange." Taylor seems to have been the first to attempt its numerical measurement. The treatment of the subject has been mostly mathematical, but a rough explanation can be given without resort to mathematical symbols. The amount of heat possessed by a gramme of air is proportional to its potential temperature as defined long since by von Bezold and, save in the comparatively rare cases where the lapse rate is adiabatic, in which case heat is almost certainly being carried upwards by convection, the higher potential temperature is found at the higher level. The interchange, therefore, of two grammes of air between different levels (and it is obvious that if one gramme is carried up another must come down somewhere else to take its place) produces in general a flow of heat downwards, since the downward-coming gramme carries with it more heat than the upward-going gramme carries back. W. Schmidt has estimated the amount of heat carried downwards across the 2-km. level in Europe by this cause as 50 gramme-calories per sq. cm. per day. The necessary interchange of mass between the strata is produced by wind, for even the lightest wind seems capable of mixing the air in a vertical direction. The mixing produced by convection will have the same effect and if the return convection currents are in a region where the lapse rate is not adiabatic the total result of the convection in carrying heat upwards may be very small.

Two important conclusions follow. Since all four causes save radiation convey heat to the lower strata, say 0 up to 4 km., those strata must be losing heat by radiation. Also, since above the region of the formation of heavy clouds neither convection nor the supply of latent heat by condensation is efficacious, the actual lapse rate there must represent the balance of two opposing tendencies, one radiation, tending towards an isothermal condition, and the other, mixing, tending to an adiabatic lapse rate.

*Radiation.*—Considerable progress has been made in the subject of radiation, solar and atmospheric, both from the observational and theoretical sides. Abbot and Fowle's valuable work has been continued, and each issue of the *Monthly Weather Review* contains an article by Kimball giving the results of observations at Washington and other stations. The value of the solar constant, 1·93 g.c. per sq. cm. per minute, has not been appreciably altered by the later observations, but the instrumental outfit has reached a greater stage of precision, and it appears that the radiant heat given out by the sun varies from week to week within small limits.

Dr. Anders Ångström (Upsala), Prof. Boutaric (Dijon), and others have contributed much useful information on the net radiation between the earth and atmosphere. Dr. Emden has contributed an important paper ("Radiation Equilibrium and Atmospheric Radiation," *Sits. Ber. Ak. Wien*, 1913, p. 55) dealing with the radiation between layers of the atmosphere. With regard to the net radiation from the earth to the sky on clear nights there seems to be a fairly general agreement that the value is from 200 to 300 g.c. per sq. cm. per day. These values have been obtained in widely different latitudes and seasons. The return radiation from the sky, excluding all solar radiations, is largely dependent on the prevailing temperature at the time; the average in England for all days, cloudy as well as clear, is about 600 gramme-calories.

*Weather Forecasts.*—During the World War, and since, large sums of money and much time have been spent on preparing forecasts. Of long-range forecasts it must be said that the position is not hopeful; in general a forecast of the weather a month ahead is a pure guess and nothing more. The British Meteorological Office has extended the period to a few days, and now mostly gives on Thursday a forecast for the week-end, with satisfactory results. With regard to the daily forecasts covering a period of 30 hours there has been a decided improvement. The extension of the area of the weather chart to cover Iceland, and the information obtained by wireless from the Atlantic have helped.

Forecasting has been and still is more or less a rule of thumb, but it depends upon the rules which govern the motions of cyclones and anticyclones, and if we could discover those rules and fully understand the causes which produce them an improvement in forecasting should follow. By the extensive use of pilot balloons a very large amount of information is now available with regard to the direction and velocity of the wind at various heights at the times when telegraphic reports are sent in to the head offices so that there is ample material showing the relation of the wind to the barometric gradient, but at present very little of this has been worked up. Much theoretical work has also been done on the gradual change from the surface wind to the gradient wind that generally lies above it. Sir Napier Shaw has contributed two useful papers ("Principia Atmospherica," *Trans. Royal Society of Edinburgh*, Dec. 1913, and "Upper Air Calculus," *J. Scott. Met. Soc.*, vol. xvi., 1913) of which a summary

is given in *The Computer's Handbook*, M.O. 223, Section II., Subsection III. Shaw has in these papers emphasized the rule that at all heights save close to the surface the path of the air particle will be along the line in which the isobaric and the geopotential surfaces intersect. The rule is admittedly not exact, and it applies only to cases of steady motion; its general acceptance is probably due to two considerations. It has been found by practical work that in laying down the direction and velocity of the wind at one or two km. height (in the absence of definite information from pilot balloons) for the use of aircraft the best that can be done is to give the gradient wind, and it is not certain that the actual wind at 500 metres differs from the gradient wind by a greater amount than is due to the errors of observation. Secondly it is apparent that a depression could not be maintained for hours together with an approximate uniformity of pressure if air were continuously passing into it or out from it; quite a trifling wind blowing systematically into an ordinary depression for a few minutes would suffice to fill it up. Hence one is led to the conclusion that the strong winds that surround a depression must in general blow along the isobaric lines.

In his *Manual of Meteorology*, Part IV, M.O. 234, Napier Shaw has also provided a valuable account of the "relation of the wind to the distribution of barometric pressure."

In connexion with the subject of forecasting, Prof. V. Bjerknes' theory of the "polar front" must be referred to. His suggestion is that cyclones are caused by the discontinuity between polar and equatorial air, that, provided the network of stations is sufficiently close, the line where the surface of discontinuity meets the earth's surface can be traced on a chart, and the cyclone will move in the direction of a line he calls the steering line. Prof. Bjerknes' views are in the *Q. J. Met. Soc.*, April 1920, vol. xlvi., No. 194, p. 119.

*Antarctic Meteorology.*—Great additions to our knowledge of the meteorology of the Antarctic regions were made by the publication of the results of Scott's Antarctic expedition of 1911. The observations were taken mostly by Dr. Simpson, who has worked them up and discussed the various problems which had been left in a more or less uncertain condition by previous expeditions. He has greatly extended our knowledge both from the observational and theoretical sides. It must suffice to state here that amongst other matters Dr. Simpson has established the anticyclonic character of the weather in the Ross Sea area, and has shown that the blizzards are not due to the passage of cyclones from W. to E. over the Antarctic Ocean.

(W. H. Di.)

**METHUEN, PAUL SANFORD,** 3RD BARON (1845– ), British field-marshal (*see* 18.298), was born Sept. 1 1845, joined the Scots Fusilier Guards in 1864, served in the Ashanti War of 1874, the Egyptian Expedition of 1882 and the Bechuanaland Expedition of 1884–5. As a major-general he served in the Indian Frontier War of 1897–8, shortly after which he was promoted lieutenant-general. On the outbreak of the South African War he went out in charge of the 1st Division, which he commanded at Belmont, Enslin, Modder river and Magersfontein; he remained in the field, engaged constantly on active operations and holding various commands, until just before the end of the conflict when he was, in March 1902, dangerously wounded and taken prisoner at Tweebosch; he was rewarded with the K.C.B. and the G.C.B. for his services in the war. He was in charge of the Eastern Command from 1904, in which year he was promoted general, until 1908, and he then went out as commander-in-chief to South Africa 1908–9. In 1911 he was promoted field-marshal. During the greater part of the World War he was governor of Malta. In 1919 he became Constable of the Tower.

**MEUSE-ARGONNE, BATTLE OF** (Sept.–Nov. 1918).—The general idea of the Meuse–Argonne attack was agreed upon in a conference between Marshal Foch, Gen. Pétain and Gen. Pershing at Bombon, on Sept. 2. What Foch really desired and had urged upon Pershing in a conference three days previous was to break up the American army, as an offensive force, immediately after the projected St. Mihiel attack, and to employ the best of its troops to reinforce the II. and IV. French Armies for a combined offensive along the front of these two armies. But Pershing firmly opposed the breaking-up of his army and insisted upon adherence to the original design of employing the main part of the American troops as an integral army unit. Foch finally acceded and gave Pershing his choice of the sector of the II. Army (from the Meuse to the Argonne, inclusive) or that of the IV. Army (from the Argonne, exclusive, to the Suippe). He chose the former.

Following this conference Foch issued a general directive for the attack, which Pétain elaborated into precise orders for the two armies concerned, those of Pershing and Gouraud. The general objective named for the combined attack was Mezières. The St. Mihiel operation was conceived as a preparatory phase (or Operation A.), to give a broader base and better communications for the later operations, notably by freeing for use the railway and roads leading to Verdun from the S. along the Meuse. The American army attack on the front Meuse–Argonne inclusive (Operation B.) and the French IV. Army attack extending from the Argonne W. to the Suippe (Operation C.) were to be simultaneous. Following some days later the French V. Army was to continue the attack W. from Reims to the Aisne (Operation D.).

The direction of attack given for Operation B. was Buzancy–Mezières, but the first objectives named were the Hindenburg line on the front Brieulles-sur-Meuse–Romagne-sous-Montfaucon–Grandpré. In fact, the French higher leaders did not at that time conceive that the attack could be carried beyond that line before winter. The American army was to be reinforced for Operation B. by 180 French airplanes, 239 French tanks and a considerable force of French artillery (1,002 heavy guns, 456 light guns and 254 trench mortars). In addition a French cavalry division stood by to take advantage of a possible break through the German lines. The American attacking troops consisted of three army corps, having three divisions each in the front line and three divisions in reserve. Only one of these front-line divisions was composed of regular troops, while of the others three of the four National Guard and three of the four National Army divisions employed lacked any previous battle experience.

The newly formed American Army Staff had been a little apprehensive of the outcome of its initial attack at St. Mihiel (Operation A.), and had in consequence designated for that attack most of its better-trained and more experienced divisions, including four of the six available regular divisions. Further, more resistance, with consequently heavier losses, was anticipated in Operation A. than proved to be the case, and it had been considered that more time would be required for resting and recruiting the divisions engaged. The results of this policy in the light of after events, turned out to be most unfortunate. Operation A. was a simple attack which, as was expressly ordered by Foch, was not to be exploited even to the extent of attacking the reserve German position across the face of the salient. The Meuse–Argonne attack, on the contrary, was to be

# MEUSE-ARGONNE, BATTLE OF

pushed to the limits of possible success. The fact that Operation B. followed so closely after Operation A., the restricted available road-net, and the need for secrecy, made it difficult to withdraw the better-trained troops from the new Woevre front and again put them in the front line.

The German position between the Meuse and the Argonne was naturally strong and had been strengthened by every possible artifice. Vauquois, a fortified hill E. of and overlooking the Aire valley, was regarded as an impregnable fortress, and Montfaucon, dominating the whole plateau, afforded not only a strong defensive position but observation and command posts which greatly aided in controlling the defence of the whole line. On the other hand the German troops in the line on the front of attack consisted of only five divisions, four of them of inferior quality, and the fifth, a Guard division, much worn from intensive fighting farther N. and sent to this supposedly quiet sector for rest. Among the German divisions immediately in rear in reserve there was only one rated first class. Thus the German infantry actually in line was outnumbered by the attackers about four to one, since the American divisions had twice the infantry strength of the German divisions, while the Americans, thanks to the reënforcing French artillery, had at the outset a decisive artillery superiority, and, altogether, 821 airplanes.

On Gen. Pershing's initiative, various feints and ruses with the employment of American tanks and reconnoitring parties E. of the Moselle as well as in and S. of the Vosges Mts., had served to distract the attention of the German High Command, and led it to expect an attack upon Metz itself or the line E. or S. of Metz rather than W. of the Meuse. The real attack had consequently the advantage of being an almost complete surprise.

Following an artillery preparation of three hours the attack was begun at dawn on Sept. 26. The first day the attack progressed well. The I. Corps, on the left, stormed Vauquois, advanced up the Aire valley to its objectives, and even made sensible progress in the Argonne forest. On the right the III. Corps crossed the difficult Forges brook with its marshy banks and also gained its objectives. But in the centre the V. Corps was held up in passing through the woods in its front, and was unable to take Montfaucon although the III. Corps had passed beyond it on its right. The second day Montfaucon was gained and the attack went forward, but not so far as had been planned.

The third day, Sept. 28, there was still less advance in the centre and not what was hoped for on the left. By this time the German reserves from outside the sector began to pour in and, by the fourth day, having nine divisions in the line, the Germans attempted powerful counter-attacks to regain some of their lost positions. The German artillery was also greatly augmented and, from the favourable flanking artillery positions on the heights E. of the Meuse and in the Argonne forest, greatly hampered the work of the American troops in what was now a pronounced salient in the American line on the plateau between the Meuse and the Aire rivers. The weather for the first three days had been favourable, but on the 28th drizzling rains set in which added to the difficulties of both the tactical handling of troops and of supply. The reconstruction of roads across no-man's-land and traffic control had been found especially difficult on the front of the centre corps on account of the depth of the shell-battered zone created by years of intensive fighting. Friction in the railway supply, as was to be expected in a new staff, was not lacking. Under these trying conditions few gains were made on the last two days of Sept., and it became evident that the inexperienced and inadequately trained divisions which had made the initial attack could accomplish little more in the way of further advance.

The difficulties in the way of supply were speedily smoothed out and the worn and tired troops soon replaced by fresh, but the disappointment in the hopes for a clean break through the German army in this its most strongly fortified and from now on most stubbornly defended sector, hopes which had been created by the striking success of the first day's attack, gave rise to exaggerated rumours of blundering in troop leadership at the front and of supply mismanagement in rear, rumours which finally so affected the French Government as to lead it and Foch to urge the substitution of a French commander and staff for the further conduct of Operation B. This was refused by Gen. Pershing on the ground that the honour of the American army was involved in this attack, and that, whether it finally fail or finally succeed, it must be carried through to the end as an American operation under an American commander and staff.

By Oct. 4 the I. Army line had been reorganized, and on that date the systematic renewal of the offensive was taken up.

West of the Argonne the attack of the IV. French Army (Operation C.), also begun on Sept. 26, had not been successful in making any appreciable advance, and Pershing was called on to loan some of his all-too-few veteran divisions to attack the keypoint of the German Champagne position, Blanc Mont. He complied with this request, and all the more willingly since it was the failure of the French attack W. of the Argonne which made the position of the American troops in the forest itself so trying. With these picked troops the IV. French Army, attacking simultaneously with the I. American Army on Oct. 4, gained Blanc Mont, and the German commander, after vain counter-attacks, ordered a withdrawal beyond the Aisne. East of the Argonne the right of the I. Corps gained an advance of 10 kilometres along the right bank of the Aire, an advance exploited three days later by bringing a flank attack on the Upper Argonne from the E., which, combined with the successful advance of the IV. Army of Gouraud, W. of the Argonne, resulted in the capture, by Oct 10, of the entire forest, and enabled the French and American armies to connect their flanks through the pass of Grandpré.

The failure of the American I. Army on Oct. 4 to gain its objectives on the eastern half of the Meuse-Aire plateau in its renewed attack of that date made it clear to Gen. Pétain that a broader base was required to push the attack beyond the main Hindenburg line, and that the possession by the Germans of the heights E. of the Meuse afforded them too favourable artillery positions and observation posts to make possible an extended advance to the N.W. of the Meuse. Accordingly, on Oct. 5. Pétain placed at the tactical disposition of the I. Army the XVII. French Corps, at the time passively holding the line E. of the Meuse, and directed that, reinforced by two or three American divisions, it should be called on to gain the line Dun-sur-Meuse–Damvillers. This attack was made Oct. 7, coincidently with a renewed attack on the west. It was partially successful and gained an advance of 6 kilometres. By Oct. 10 the I. Army was, in general, up to the rearmost carefully prepared positions of the German army in this region, known as the Kriemhilde Stellung. On Oct. 11 Pétain called for a renewal of the attack on both banks of the Meuse with the same objectives as before on the E. bank, but with the breaking of the Kriemhilde line and the capture of Buzancy as the objectives on the W. bank.

This attack was carried out on Oct. 14 and resulted in small but material gains, including the Côte Dame Marie, Cunel and Romagne-sous-Montfaucon. The troops by this time were well worn. There was no adequate replacement system and, notwithstanding the breaking-up of newly arriving divisions, it was impossible to keep units at full strength. For the remainder of the month the I. Army had of necessity to limit itself to local operations and to preparation for a systematic renewal of the offensive. On Oct. 12 the I. Army front, which had hitherto extended E. to the Moselle, was divided into two army sectors and, on the 16th, Gen. Pershing transferred the immediate command of the I. Army to Lt.-Gen. Liggett, and exercised supervision, as group commander, of both armies. On Oct. 21 Pershing ordered a renewal of the offensive with plans for a break-through for Oct. 28, but this attack was, on request, deferred until Nov. 1 to enable the IV. French Army to make plans for attacking simultaneously.

On the German side there was no lack of appreciation by either the opposing army commander or General Headquarters as to the threat which the American attack constituted. Von der Marwitz declared to his army, on Oct. 1, after the first break

through his lines: " . . . The heaviest part of the task will thus fall on the V. Army . . . in the coming weeks, and the safety of the Fatherland will be in its hands. It is on the firm resistance of the Verdun front that depends the fate of a great part of the Western Front, perhaps even of our nation. . . . " Hindenburg in his memoirs added on this subject: "It was plain that this situation could not last. Our armies were too weak and too tired. Moreover, the pressure which the American masses were putting upon our most sensitive point in the region of the Meuse was too strong."

It is debatable whether a quicker perception on the part of German General Headquarters of the threat of the Meuse-Argonne attack might not have led to a greater concentration of effort against it and a speedier evacuation of the French territory to the N., W. of the Meuse, and thus to a prolongation of the resistance of the German army. Hindenburg and Ludendorff appear, however, to have been at this time preoccupied with events in the Near East (the surrender of Bulgaria occurred on Sept. 29), and the home political situation in both Germany and Austria. In any case, without apparent forethought of consequences, the German strategic reserve of fresh divisions was doled out piecemeal by G.H.Q. until, by Nov. 1. it had ceased to exist. Thereafter troops could be neither relieved nor reinforced. The result was that the general, carefully prepared attack on Nov. 1 broke through the enemy's line at all points, and thenceforth it was a case of rapid pursuit with occasional rear-guard actions until the Armistice on Nov. 11. The chief preoccupation on the Allied side during this pursuit was holding the troops in leash in their sectors and determining who should have the honour of first entering important towns such as Sedan. The main line of the Carignan–Sedan railway, the real objective of the Meuse-Argonne attack, was brought under artillery fire on Nov. 3 and reached, by the I. and V. Corps, on Nov. 7, while the III. Corps had, by the same date, forced the crossing of the Meuse and advanced 10 kilometres to the N. and E.

The I. Army, during the Meuse-Argonne operation, had employed 22 American divisions and 4 French divisions. Of the 22 American divisions 12 were engaged on other fronts during a part of the period (Sept. 26 to Nov. 11). On the German side, in addition to the 5 divisions originally in the sector, 42 divisions had, in the course of the battle, been thrown into line. Thus, in all, one-fourth of the German army in the W. had been engaged and decisively beaten by the I. American Army, although occupying successively the numerous and strong defensive positions prepared long in advance. The strength of the American troops involved was, in the aggregate, about 750,000 men, their losses 117,000 killed and wounded, their captures 26,000 prisoners and 846 guns.

**MEXICO** (*see* 18.317).—The ten years of revolutionary conditions following the elimination of Porfirio Díaz had a profound effect on all phases of the national life. A census was impossible. The appended last official count, 1910, gave a total pop. of 15,063,207. The table[1] gives the pop. of the states and territories, arranged in descending order, according to the 1910 census.

In 1912 the pop. was estimated at 15,501,684. Since then there has been a movement toward the cities for safety from banditry, and across the borders for employment and political refuge. Mexico City was estimated in 1920 to contain over 900,000 inhabitants. Decrease has come in the rural districts from the causes mentioned, as well as from famine and influenza. A small return movement set in after conditions became more peaceful. In Jan. 1921 foreign residents numbered about 14,000 Americans, as many Spaniards, 4,000 each of Germans, English and French, and 5,000 Chinese and 3,300 Japanese.

*Communications.*—The revolution was an almost continuous struggle for possession of the railways. The result was disastrous to practically every line. Between 1910 and 1913 the Southern Pacific of Mexico suffered traffic losses of $3,000,000. The Mexican Central to Laredo gave the most regular service, running passenger trains and vast amounts of freight to the border with only temporary interruptions. Much freight in northern Mexico was handled by privately owned trains; in 1919, 30 such trains were operated, mostly by American mining companies. From 1910 to 1919 over 10,000 freight cars, about 175 passenger and express cars and a huge number of locomotives were destroyed. In 1919 the Government was using on five systems 837 standard-gauge and 302 narrow-gauge locomotives, 520 standard-gauge and 259 narrow-gauge passenger cars and 12,293 standard-gauge and 2,810 narrow-gauge freight cars. Military campaigns and private use of railways by military officers reduced railway efficiency, and peculation almost prostrated the service. In 1920, 500 freight and passenger cars were bought, and a number of locomotives ordered, in the United States. On Jan. 1 1921 free interchange of traffic between the United States and Mexico, suspended since 1915, was resumed. Since 1914 the Yucatecan roads have been operated by the State. In May 1919 500 m. were in operation. In the year ending June 30 1918 the 8,119 m. of national railways carried 393,968 tons of forest products, 1,236,719 tons of agricultural products, 216,443 tons of animals and animal products, 1,938,105 tons of minerals and 372,475 tons of general merchandise. Gross receipts for the same year were $29,240,485; operating expenses, $19,151,808; net operating income, $10,088,677. The Mexican railway from Vera Cruz to Mexico City was returned to its British owners, with indemnities pending, in the spring of 1920. Lines in Morelos were opened about the same time. War on the railways practically ceased with the success of Obregón. In the spring of 1921 return of the national railways, seized by Carranza in 1914, was being discussed. The Government might still retain the 51% of the stock, as it was acquired in 1906 by Limantour, Díaz's Minister of Finance, and would be liable for indemnities proportionate to earnings for the five years prior to 1914, returning the lines in the condition in which they were received. The liability of the Government was estimated at 990,000,000 pesos of a nominal value of $.50.

*Commerce.*—The total trade in 1911 was £20,583,578 in imports and £29,375,214 in exports; for 1912, £18,266,231 in imports and £29,798,912 in exports; for 1913, £19,577,233 in imports and £13,088,508 in exports. Trade with the United States was in 1917, $110,829,375 in imports and $130,526,935 in exports; for 1918, $97,788,736 in imports and $138,643,427 in exports; for 1919, $131,451,901 in imports and $158,926,376 in exports; for 1920, $143,785,526 in imports and $168,033,626 in exports. The total trade, estimated at $70,000,000 in 1890, was over $300,000,000 in 1919. Exports to the United States for 1917–9 were 70% greater

| States or Territories | Area in sq. km. | Population 1910 | Per cent of increase in 10 years | Density per sq. km. 1910 |

[1] From A. Petermann's *Mitteilungen aus Justus Perthes' Geographischer Anstalt*, 57. Jahrgang, 1911, II. Halbband, p. 191.

than in 1912–4, and imports thence 110% greater. American trade was about 85% of the total, the United Kingdom ranking second. The chief commodities exported in 1920 were sisal, crude petroleum, copper, raw cotton, hides, coffee and lead. Imports were manufactures, as of iron pipe, cotton cloths, flour, sugar, motor vehicles, lard, shoes and lumber. In 1912 the sale of Yucatecan henequin was put under control of a *comisión reguladora* on a plan similar to that for Brazilian coffee valorization. Sales from 1915 to 1918 amounted to 2,205,425 bales of 380 lb. each, a yearly average of 735,141. From 1916 to 1918 production decreased 100,000 bales yearly, due to disorders and labour shortage. Exports from Progreso to the United States in 1917 were $35,881,988, consisting of chicle, coffee, henequin, hides, logwood, etc.

*Agriculture.*—Production was unequal, due to war, drought and lack of capital. In 1918 exports of products and live stock were valued at $74,253,500. Banana exportation rose to an annual value of $5,000,000. The normal maize crop, 110,000,000 bus., is less than the consumption. Two crops, followed by one of wheat, are produced in some areas. Chihuahua in 1920 produced 44,000,000 lb. more maize than was needed for local consumption. The barley crop is about 7,000,000 bus.; rice, 1,250,000 bus. The frijole (bean) crop, worth $7,500,000, is locally consumed. Garbanzos (chick-peas) exported from Guaymas in 1918 totalled 25,000 tons, worth $4,500,000. In 1919 32,742 tons were exported. The cotton crop of 1918 was 71,266 bales. The 1919 and 1920 crops were poor, due to pests and climatic factors; 90% of the cotton is produced in the Laguna district of Coahuila and Durango. About 90,000 bales are used in Mexican factories, operated by foreigners. Vanilla-bean export in 1919 was 197,403 kgm., worth 2,333,264 pesos. Sesame, or ajonjoli, in 1919 was produced to the extent of 20,000 tons, worth $150 to $200 per ton. Sugar production, as much as 160,000 tons before the revolution, after a temporary fall had risen to 110,000 in 1920. Only 1-45th of the possible sugar land is used. The republic could produce 7,000,000 tons. Coffee decreased only in the rebel district of Vera Cruz. The normal crop is from 77,000,000 to 110,000,000 pounds. In 1919 Mexico imported 1,000,000 lb. of Brazilian coffee from the United States. Tobacco production, normally 11,000,000 kgm., was 2,000,000 in 1919; the 1920 crop was estimated at three times that figure. Guayule rubber in 1918 amounted to 2,656,769 lb., worth $1,004,561. Before the revolution there were 5,000,000 head of cattle, 800,000 horses, 300,000 mules, 250,000 asses, 5,000,000 sheep, 4,000,000 goats and 600,000 hogs. In 1920 it was estimated that stock had decreased 75% since 1910, although there had been some increase since 1917. Meat prices rose 100% in 1919–20. Hides were exported to the United States. Lumber mills are increasing. In 1917 Chihuahua produced 19,500,000 ft. from the Madera and Pearson mills. Mahogany from the south is annually worth $600,000. Twenty-five varieties of hard-wood and cedar annually produce $1,000,000.

*Mining.*—There was marked resumption of production in 1918 and 1919. Low prices in 1920 reduced operations to high-grade ores. In 1918 exports were worth $34,716,000; in 1919 $10,577,393. In 1919 there were 5,804 mines of silver, 1,800 of gold, 988 of copper, 118 of lead and 73 of zinc. A new law of mining imposts was decreed June 27 1919. In the same year the Japanese began to buy iron-ore deposits. Coal is produced only in Coahuila, though there are deposits in Sinaloa. Mineral production in the leading lines for 1916–9 was as follows (in kgm.):—

| Metals | 1916 | 1917 | 1918 | 1919 |
|---|---|---|---|---|
| Gold | 11,748 | 23,543 | 25,313 | 22,944 |
| Silver | 926,142 | 1,306,988 | 1,944,542 | 1,949,673 |
| Copper | 28,411,248 | 50,985,923 | 70,223,454 | 50,893,612 |
| Lead | 19,970,986 | 64,124,752 | 98,837,154 | 67,378,353 |
| Zinc | 37,449,226 | 14,757,333 | 20,698,995 | 8,665,413 |
| Antimony | 828,767 | 2,646,544 | 3,268,546 | 627,704 |
| Tin | 292 | 9,214 | 13,537 | 2,117 |
| Tungsten | 12,250 | 187,637 | 149,486 | 29,292 |

Molybdenum, manganese, mercury, arsenic and amorphous graphite were also extensively produced.

*Petroleum.*—Petroleum is produced in the Ebano, Pánuco, Huasteca, Tuxpam and Tehuantepec-Tabasco regions. The area occupied by companies in 1919 was 4,064,870 ac.; their annual rents came to $3,449,033; several companies were paying from $200 to $400 per acre. The companies operating numbered 155. In Feb. 1919 114 new wells were being drilled. In 1920 there were 770 m. of pipe-line, with 2,000,000 bar. capacity; total wells, 1,103. The largest well, Cerro Azul No. 7, was capable of producing 370,000 bar. daily. Tanks numbered 902, with capacity of 50,000,000 barrels. Investments in Tuxpam and Tampico alone were estimated at $1,000,000,000. Export duties collected in 1917, $6,854,537; 1918, $10,135,992; 1919, $15,203,986. Export duties were first levied in 1914. Uncollected royalties, protested as confiscatory, for 1918 and 1919 were $4,500,000. In May 1916 a monthly inspection tax of 150 pesos was fixed; 50 companies out of 373 then operating refused to pay it. The duties in Aug. 1920 were $ .10 to $ .165 per bar. on crude and high-density fuel oils; on gasoline $ .09 per gal.; on kerosene, about $ .01 per gallon. Valuation was based on quotations of American ports minus transportation costs. Dividends of the best-paying companies in 1920 ran from 24% to 40%, after deducting reserves. Production multiplied more than three times in seven years, or 54 times since 1907. Official figures for production are as follows:—

| | Barrels | | Barrels |
|---|---|---|---|
| 1901 | 10,345 | 1911 | 12,552,788 |
| 1902 | 40,000 | 1912 | 16,558,215 |
| 1903 | 75,375 | 1913 | 25,696,291 |
| 1904 | 125,625 | 1914 | 26,235,403 |
| 1905 | 251,250 | 1915 | 32,910,508 |
| 1906 | 502,500 | 1916 | 40,545,712 |
| 1907 | 1,005,000 | 1917 | 55,292,770 |
| 1908 | 3,932,000 | 1918 | 63,828,326 |
| 1909 | 2,713,500 | 1919 | 80,557,229 |
| 1910 | 3,634,080 | 1920 | 153,797,036* |

*This 1920 figure is for exportation only, and not total production.

Refined oils were in 1920 34% of the total. The United States took 73% of the output in 1918. Exports in 1917 were worth $26,838,063, and in 1918 $70,278,776. President Carranza's oil decrees of Feb. 19, July 31 and Aug. 8 and 12 1918, which fixed taxes and royalties, controlled issue of titles, and established conditions of concessions, were resisted by operators as without constitutional authority and contravening acquired rights. Protests by Governments whose nationals were concerned, and suits at law by the companies, had not been settled in Nov. 1921, though a suit favourable to the Texas Oil Co. indicated the prospective amicable solution of the oil situation.

*Foreign Investments.*—The Mexican Government in 1919 estimated investments in the republic as follows: American, $1,057,770,000; English, $331,302,800; French, $143,446,000; Mexican investments, $793,187,242; grand total, including those of other countries, $2,434,241,422. Claims for damage done to American investments are estimated at between $500,000,000 and $1,000,000,000.

*National Debt.*—In 1908 the total internal and external debt was estimated at £44,101,607. On Dec. 31 1919 the external debt, including unpaid interest, was £69,792,229; the internal debt, 138,795,550 pesos. Middleton, in *Industrial Mexico*, stated the debt for 1919 at $350,181,047.47, besides the railway debt, which was $238,740,393 on June 30 1918, and besides unpaid interest to Jan. 1 1919 $51,824,139. There is no completely authoritative statement of the debt. The International Bankers' Committee on Mexico, organized Feb. 24 1919, acts for the holders of Mexican securities. Rehabilitation of finances was discussed repeatedly in 1919, 1920 and 1921, but without action.

*Banking and Credit.*—Banking in 1919 was practically confined to foreign-exchange transactions; commercial credits, mostly at 30 days, were increasing. Deposits were not sought. There was lack of confidence, due to the frequent revolutionary "borrowings" of prior years. American trade in 1919–20 was on a cash basis or on sight drafts against shipping documents. In 1913 there were 20 banks of emission, with assets worth $425,500,000; four mortgage banks, with assets worth $43,762,000; and six banks of promotion, with assets worth $83,000,000. There were three other Mexican banks, six foreign ones, and the old colonial Monte de Piedad. Since 1914 there have been no banks at all in Mexico within the meaning of the banking law of 1897. Plans for a single bank of issue as a centre of nationalized reorganization have been under discussion since Sept. 1918. An initiative providing a new banking system was sent to Congress by President Obregón in Feb. 1921. The single bank of issue is to be accompanied by other special banks for commercial, industrial and agricultural needs. Other proposed legislation which might have indirect effects on economic conditions are the new agrarian law and the educational bill, both of which were sent to Congress in Feb. 1921. An executive decree of Jan. 31 1921 provided for the return to owners of banks declared in liquidation Dec. 14 1916. These banks were to be restored to activity or liquidated, according to their financial condition. The most important banks affected by this decree, and the amounts of their paper notes in circulation respectively, were the Banco Nacional de Mexico, 32,571,969 pesos; the Banco de Londres y Mexico, 26,256,141 pesos; the Banco Oriental, 21,831,349 pesos; and the Banco Minero de Chihuahua, 8,001,619 pesos.

*History.*—The decade 1910–20 was a period of attempted social revolution misdirected and unrealized. The closing years of the rule of Díaz were marked by events portentous of the troubles which ensued. The financial depression of the United States in 1907 was reflected in Mexico in 1908. Financial measures, which included nationalization of the railways and reorganization of the banking system, placed a severe burden on the country. There were serious crop failures due to frosts and drought. In Oct. 1909 free importation of grains was decreed, and in April 1910 the President was authorized to expend a million pesos for importation of corn and beans. In the midst of these economic perplexities the centennial of Mexican independence

was celebrated throughout the country. Nearly every city and hamlet initiated commemorative public works. Thirty-one foreign nations participated in the celebrations in the capital during Sept. 1910. Numerous public buildings and monuments were begun, some of which were not completed. Mexico seemed at the height of power and prosperity. But the consequences of a long period of autocracy were about to appear. Accompanying the celebration was the national election for president and vice-president. It had been the subject of much conjecture, particularly since 1908, when Díaz had declared in the Creelman interview that the Mexicans were ready for democracy, that he would permit political campaigning by those not supporting Government candidates, and would surrender the presidency to a legally elected successor. The declaration was taken seriously, especially by certain radicals, the most active of whom had long been agitating against Díaz from the security of American border cities. The Government had endeavoured to promote in turn the candidacies of Limantour and Ramón Corral, but these had failed. The failure of Gen. Reyes to enter the final race brought advantage to the anti-Reëlectionists, who were led by Francisco I. Madero.

*The Madero Revolution.*—In view of the probable return of Díaz to the presidency for the seventh time, there was a renewal of the agitation for political renovation. Madero's personal campaign, conducted throughout a great part of the republic, was reinforced by his book, *La sucesión presidencial en 1910*, which was issued first in 1908 and had reached three editions by the spring of 1910. It attacked the Díaz system in measured language; his propaganda was at first ignored by the Government, but when his influence became too great he was arrested for sedition at Monterey on June 7 1910, and confined in San Luis Potosí. Thence he escaped in Oct. to San Antonio, Tex., where he and his associates prepared the Plan de San Luis Potosí. This plan declared for effective suffrage, no reëlection, refusal to recognize the Díaz Government elected on Sept. 27, the subdivision of rural agrarian property, and the provisional assumption of the presidency by Madero. At a meeting of the revolutionary junta in San Antonio on Nov. 6 it was agreed that outbreaks against Díaz should occur simultaneously in various places on Nov. 20. There were several premature disorders. In Chihuahua Cástulo Herrera, a trade unionist, and Pascual Orozco, a small commission merchant, began a movement against Gov. Terrazas. In Mexico City on Nov. 9 there were riots caused by a report that a Mexican citizen had been lynched in the United States. Similar disorders occurred in Guadalajara, Chihuahua and Piedras Negras. The first clear indication of the coming revolt was due to the discovery of plotting in Puebla by Dr. Aquiles Serdán, who was attacked and killed in his own house, which he had fortified. The Government then announced that a plot against it had been discovered, and a reign of terror began. The radical press was silenced, the jails were filled with political prisoners. The anti-Reëlectionists fled from the capital. Chihuahua was the scene of much fighting, in which the Government was successful, so that by the end of Dec. Madero was obliged to flee to the United States. The Government was then combating uprisings in a dozen states. Meantime Díaz attempted to appease the popular movement. He suspended personal guarantees, called for the resignation of his Cabinet, chose new ministers supposed to be more in sympathy with changed political thought, and attempted reform legislation. President Taft, who had kept forces along the Río Grande to watch the border, now augmented them by 20,000, and sent warships to Mexican waters. When Díaz read his message to Congress on April 1 he promised to initiate a law prohibiting reëlection of the president, vice-president, or the governors of states. But the results were unsatisfactory, and Díaz entered into negotiations with Madero. The latter demanded the resignation of the president and vice-president, and negotiations were broken off. Then Ciudad Juárez fell to the rebels, and Madero entered it on May 10. Having earlier assumed the title of provisional president, he here organized a civil government.

*The ad-Interim Presidency.*—The success of the revolution at Ciudad Juárez, coupled with similar victories at Pachuca and Cuernavaca, brought the Government to terms. It was agreed by representatives of Díaz that he and Vice-President Corral would resign before the end of May; that Madero should give up his claim to the provisional presidency in favour of Francisco de la Barra, who should issue a call for elections. In his Cabinet and in the state Governments de la Barra was to place certain officers of the revolution. The pact was signed May 21 1911. Many important cities throughout the country had fallen before the popular movement. After two days of mob activity in the capital the resignations of Díaz and Corral were offered and accepted on May 25. De la Barra assumed office, and Díaz left the country next day. The actual power was in the hands of Madero, who had offices in the capital. His triumphal entry on June 7 had followed a progress from Ciudad Juárez marked by demonstrations of national joy. The *ad-interim* Government was conspicuous for political jockeying, of which the chief example was the successful effort of Madero to dissociate from his candidacy that of Francisco Vázquez Gómez for the vice-presidency and to support José María Pino Suárez as candidate. At the elections Madero and Pino Suárez received the greatest number of votes that had ever been cast in Mexico. Inaugurated on Nov. 6, for the term ending Nov. 30 1916, Madero soon found himself the tool of the Científico group, lacking power and will to act for himself. He began to neglect his earlier supporters and to cater to various groups of the Opposition. Unwise manipulations soon emptied the treasury of a surplus of about 65,000,000 pesos which Díaz had left. Madero chose for the Cabinet his relatives and other Científicos. This Científico group did little to redeem the promises of the Plan de San Luis Potosí. The army was retained at great expense, for fear of a counter-revolt. Ernesto Madero, Minister of Hacienda, played into the hands of the clericals, neglecting enforcement of the Laws of Reform, and finally denying that lands had been promised to the people. Madero, however, asked Congress to create a "National Savings Fund," which should provide a loan of 250,000,000 pesos with which to buy lands for distribution. The committee in charge was composed of the Madero family and other large landholders, and made little progress in its programme. Madero's recognition of the old Congress was a source of weakness. In other matters there was autocracy of the old type. The former revolutionary associates of Madero took the field against him to fight for the lands which they had been promised. Revolt began at the time of his inauguration, and soon became widespread. The national army was continually engaged with insurgents led by Zapata, Reyes and others. The old Díaz favourites resented the benefits showered upon the new group. The Cabinet began to break up, and the state of Oaxaca refused to recognize the Madero Government. Orozco, military governor of Chihuahua, turned against his chief in Feb. 1912, and there was much fighting, in which many foreigners were killed. Thousands of Mexicans fled the country. Conditions during the summer of 1912 were extremely bad. On March 14 President Taft prohibited shipments of arms to Madero's opponents. American residents of Mexico, warned to leave, were brought out in great numbers, the U.S. Congress appropriating $100,000 for their aid. Rebel successes in the north deprived Madero of Chihuahua, Durango and Sinaloa. Zapata had broken with the Government and his forces had almost reached the suburbs of the capital.

*The Huerta Coup.*—On Oct. 12 1912 Felix Díaz, nephew of the ex-president, revolted in Vera Cruz, but was promptly captured and imprisoned in Mexico City, Madero reprieving him from execution, to which he had been sentenced. On Feb. 9 1913 the students of the military college of Tlalpam marched to the rescue of Díaz and Bernardo Reyes (the latter had been delivered to Mexico by the United States earlier), set them free and, under their leadership, joined some 5,000 disaffected troops which held the Ciudadela (the arsenal), defying the Madero Government. For several days the fire of those in revolt and that of the Government forces swept over the business part of the city between the Ciudadela and the National Palace, killing hundreds of people. Finally Gen. Victoriano Huerta, recently placed at

the head of the Government troops in place of Gen. Villar, who had been wounded, turned traitor to Madero, caused his arrest and that of Pino Suárez in the National Palace on Feb. 19, and forced them to resign. He eliminated Díaz, who was a nullity. Congress hastily accepted the resignations, and Pedro Lascuráin, as Minister of Foreign Relations, held the chief executive power for about 40 minutes, during which he made Huerta Minister of Gobernación. Lascuráin then resigned, leaving Huerta constitutionally at the head of the nation. Madero and Pino Suárez were assassinated on Feb. 22, on the pretext that they had been killed in the course of an attempt to rescue them, after having been promised safe-conduct on board a vessel at Vera Cruz. In Nov. 1920 their alleged assassin, ex-Gen. Francisco Cárdenas, committed suicide in Guatemala after his arrest for extradition at the request of the Mexican Government. Every effort was made by Huerta to obtain recognition by the United States, but President Wilson, believing that Huerta had risen to power by political murder and did not represent the will of the Mexican people, refused recognition and soon demanded that an election be held in which all Mexican factions should participate and acquiesce, Huerta not standing for office. This attitude marked a new phase in the foreign policy of the United States. It began a period of direct intervention. The American ambassador, Henry Lane Wilson, who had congratulated Huerta upon his accession to the supreme power, was recalled and caused to resign on July 4 1913. Though several foreign Powers had recognized the new Government, the example of the United States was followed by Argentina, Brazil, and Chile, and in the end proved decisive.

*Huerta as Dictator.*—The struggle of Huerta for control of the country was going against him. Harshly criticised as a murderer by members of Congress, he arrested 110 members, and on Oct. 10 assumed complete control of the legislative and judicial powers, adding these to his executive functions. This assumption of dictatorship brought a message of solicitude for the imprisoned Congressmen from the American Government. The revolution which had sprung up under Venustiano Carranza of Coahuila, simultaneously with Huerta's seizure of the executive power, was now strongly led in the west by Gens. Buelna, Cabrera and Alvaro Obregón; in the north and centre by Francisco Villa, Felipe Angeles, Pablo González and Antonio I. Villareal; in the south by Zapata, and in Yucatán by Salvador Alvarado. Huerta was hemmed in to the central plateau. The revolutionary movement was conducted under the pronouncement of Carranza, and was known as the Plan de Guadalupe, which declared for the preservation of the national constitution by a Constitutionalist army, of which Carranza was declared the first chief. Numerous successes by the revolutionaries, among which was Villa's capture of Torreón in March 1914, combined with the Tampico incident, hastened the fall of Huerta. A boatload of American marines from the "Dolphin," anchored at Tampico, made a landing within proscribed area on April 10, and were arrested by a Huerta subordinate. Though they were immediately set at liberty with regrets, the American commander demanded a salute to the American flag, in which demand he was upheld by President Wilson. Huerta had been meantime especially irritated by Wilson's personal emissary, John Lind, sent to Mexico in Aug. 1913, who asked that elections should be called in which Huerta should not stand. Huerta's refusal to comply with the terms of Adml. Mayo's ultimatum resulted in the American seizure of Vera Cruz on April 21 1914. Huerta's appeal to his Mexican opponents to join in repelling the invasion was without effect, largely through the agency of Francisco Villa, who opposed Carranza in this question of policy. Harassed on all sides, urged by the foreign ministers to yield to Wilson, unable to make loans, or to effect peace with the Constitutionalists, Huerta severed diplomatic relations with the United States on April 22. The tensity of the situation was soon relieved by the proffer of their good offices for mediation by Argentina, Brazil and Chile. The United States and Huerta accepted. Carranza did so in principle, but his agents took no active part in the negotiations; he had already been designated provisional president by his faction. Effort was made in June, at the Niagara Falls Conference, to find a provisional president acceptable to all parties. This failed, but it was demonstrated that Huerta could not obtain recognition. Yet he attempted to hold an election, the result being a fiasco, whereupon he resigned, July 15 1914, in favour of Francisco Carbajal. The latter ruled less than a month, leaving the city on Aug. 13, and making Carranza Minister of Foreign Relations at the request of the American Government. On Aug. 21 Carranza entered the capital.

*The Constitutionalists.*—Factional differences among the victors now became open. Zapata's Plan de Ayala, demanding agrarian reforms, was rejected by Carranza. Villa had become antagonistic over the leadership of the campaign against the city of Mexico, which he had captured on April 2 1915. On Sept. 12 Carranza published a call for the election of a non-military president, but the Constitutional generals called a convention on Oct. 1 at Mexico City to choose a provisional president. Carranza declared he would not accept such a position, but would offer his candidacy at the regular election. Villa demanded that Carranza be eliminated, to which Carranza consented provided Villa and Zapata should leave the country. The Convention rejected Carranza's resignation, but moved to Aguascalientes, which was under Villa's control, and there accepted it. Carranza repudiated the Convention, which chose Gen. Eulalio Gutiérrez provisional president for 20 days, and placed Villa in command of forces ordered to advance on the capital. He drove Carranza out on Nov. 20. Carranza moved to Vera Cruz, entering it as the Americans, delayed in their evacuation, moved out on Nov. 23. Zapata entered Mexico City Nov. 24, Villa following him on Dec. 3, the Zapatistas returning again in March. During 1915 the executive power was claimed by four different factions. The status of foreigners at this time was most unhappy. The Spaniards suffered especially, many of them, including their minister, being expelled. In March President Wilson secured permission from the various Mexican leaders to remove foreigners from the capital under American protection.

During 1914 Villa had been much in the public view. He had set up a government in northern Mexico, and seemed for a time to be the man who could restore peace. Emissaries were sent to him by Wilson, but in April 1915 Gen. Obregón defeated him at Celaya and later at León. In Sept. he drove him from Saltillo and Torreón. This gave to Carranza control of all the states save Sonora, Chihuahua and Morelos. After Villa's defeat President Wilson indicated a more vigorous policy by urging the leaders to forget their quarrels lest the United States "use means to help Mexico save herself and help her people." In Aug. 1915 Argentina, Brazil, Chile, Bolivia, Guatemala and Uruguay urged the Mexicans to form a provisional government and call a general election. Carranza protested against this "new policy of interference." The U.S. Department of State joined in the appeal of the Powers named above, calling for a conference and proffering help. Carranza again rejected interference, being at the time successful against Villa, who, being unsuccessful, accepted. A conference of the Powers named met in Sept. and agreed to recognize the faction which after three weeks should show greatest success in maintaining order. This decision gave Carranza the decided advantage, and he was recognized as head of the *de-facto* Government on Oct. 19 by nine American Powers.

*The de-Facto Government.*—Formal diplomatic relations between Mexico and the United States were resumed in Dec., after an interval of two and a half years, by the appointment of Henry P. Fletcher as ambassador, and the reception at Washington of Eliseo Arredondo as representative of the new Mexican Government. The principal European Powers soon followed suit. Fletcher did not go to Mexico until some time later; his residence was short and intermittent, no doubt as a remonstrance against the attitude assumed by the Carranza Government. But the piqued Villistas were still to be reckoned with. On Jan. 10 1916 18 Americans were shot down by them at Santa Ysabel while going into Mexico to reopen mines at Carranza's solicitation. The U.S. Congress passed resolutions demanding interveation. Carranza promised punishment of the perpetrators

of the atrocity; later two Villa leaders, one of them said to be responsible for it, were executed.

*The Pershing Expedition.*—On March 9 1916 Villa raided Columbus, N.M., killing 17 Americans. United States troops pursued him on a "hot trail," the pursuit becoming on the 15th a punitive expedition under Gen. Pershing. It was announced as an effort to help Mexico while scrupulously avoiding offence to her sovereignty. This attitude led to niceties about use of Mexican railways which doomed the expedition to failure. It roused fierce resentment in Mexico, being condemned by both Americans and Mexicans for diametrically opposite reasons. Carranza had given qualified and reluctant consent to it, but soon began to object, asking how far American troops would penetrate and how long they would remain. There were 12,000 American soldiers in Mexico and 18,000 on the border, the latter number soon being largely increased. The expedition was halted near Parral after a clash with Villa sympathizers. General Obregón, Minister of War, conferred with Gens. Scott and Funston at El Paso, urging withdrawal. The Carranza troops failed to aid in the attempt to capture the bandit leader. The American State Department on May 10 called upon Americans still in Mexico to leave the country. On May 22 Carranza protested sharply against the "invasion and violation of sovereignty." The attempt to take Villa was then ostensibly given up, for he had been wounded and was reported dead. Forces of the United States remained in Mexico only as security against disorders, and Carranza was so informed. On June 21 a troop of American cavalry, moving (against the expressed will of Carranza conveyed by Gen. Treviño on June 16) "in a direction other than northward," was attacked at Carrizal. A number of negro troopers were killed and about a score captured; the latter were released upon the sharp demand of the United States. In July the American forces were moving northward, and Carranza expressed readiness to discuss remedies for the situation, suggesting Hispanic-American mediation. Upon Secretary Lansing's acceptance, a commission sat from Sept. 1916 until Jan. 15 1917, adjourning with no result because Carranza denied American right to send troops into Mexico in pursuit of raiders. During the remainder of his rule frequent crossings of the border occurred, with only *pro-forma* objection. On Feb. 5 the withdrawal of the punitive expedition was complete. It had been in Mexico nearly 11 months, had engaged over 100,000 militia on the border in addition to the invading troops, and had cost over $130,000,000.

*The Constitution of 1917.*—In Nov. and Dec. of 1916 a convention, composed of members of the Carranza party only, met at Querétaro to amend the constitution. It was soon decided that a new instrument was needed, and one was drawn up after short deliberation. It is remarkable for its advanced position on nationalization of natural resources and its attempt to provide definite protection for the labouring classes. It abolishes the vice-presidency and makes the president ineligible to succeed himself. There are also provisions which leave the president complete discretion with regard to ejection of foreigners, and generous control of legislation. The provisions against property-owning by churches are sweeping, though religion is tolerated. The constitution was promulgated on Feb. 5. Carranza was elected president on March 11 1917.

*The Petroleum Controversy.*—Difficulties arose out of the policy of nationalization under executive decrees of Carranza in pursuance of the theory embodied in article 27 of the constitution, which restored petroleum to the nation as an inalienable national resource. The legislation under Díaz had been thought to assure purchasers of superficial property in their possession of the subsoil products. By decree of Feb. 19 1918 Carranza imposed royalties and area taxes and graduated ground rents. A second decree of July 31, attempting to coerce oil operators into acceptance of the nationalization programme, was followed by others of Aug. 8 and 12 with the same purport. The Mexican juridical theory was that petroleum, being movable under the surface, is not the property of the owner of the superficies until he has brought it to the surface; hence exploitation, even on privately owned land, lies within control of the Government. The foreign attitude, as shown by remonstrances against the decrees made through diplomatic channels beginning April 2 1918, is that any exaction of payments by the Mexican Government under colour of national ownership of petroleum denies the right of direct dominion which was acquired by the present owners, and must be resisted as confiscatory and subversive of the theory of private ownership and contractual obligation. There seemed to be little likelihood, up to Nov. 1921, of change in the Mexican determination that Article 27 should stand as written but should not be construed retroactively as had at first been intimated. The same firmness was shown by petroleum operators, who stood upon "acquired rights," acting through diplomatic channels. The Mexican conception of the status of subsoil products is that the Díaz legislation, giving title to subsoil products with the superficies, was unconstitutional, reversing the basic law of the Spanish period and violating article 72 of the constitution of 1857. The oil interests distrust Congressional legislation to readjust their claims, believing that it can be too easily changed by succeeding Congresses. Hence they desire constitutional changes. Their appeals, pending during the closing months of 1920 before the Mexican Supreme Court, made the claim that the presidential decrees limiting their tenure and production were unconstitutional. Further decrees by Carranza in Jan. 1920 made it possible for the oil companies to resume operations in which they had been stopped because they would not obey the earlier decrees; this action was without prejudice to the attitude of either party pending remedial legislation by Congress, which had not yet been enacted in Nov. 1921.

During 1918 the Carranza Government seemed to grow stronger. A food shortage was relieved, and attempts were made to reorganize the national finances. But the oil controversy weakened the power of Carranza abroad, and the shameless corruption of his Government alienated many friends. In that and the following year rebel activities were widespread, as were deeds of violence committed against both foreigners and Mexicans. The abduction for $150,000 ransom of William O. Jenkins, U.S. consular agent, at Puebla on Oct. 19 1919 aroused intense excitement, especially after his arrest by the Mexican authorities on charges of complicity in the deed. The U.S. Department of State demanded his release, which was refused. He was released on bail against his will, but on Dec. 5 1920 all charges against him were dismissed. During the World War Mexico observed a "rigorous" neutrality, so described by Carranza in his message to Congress of April 15 1915, but this covered an official hostility to the Allied Powers fathered by German sympathies. Carranza on Feb. 13 1917 urged an embargo by American nations on food and munitions to the belligerents, at a time when such action would have benefited Germany alone. The sentiment of the people in favour of the Allies was encouraged by French, Italian and American committees. The interception and publication by the United States of the infamous Zimmermann note, in which effort was made to align Japan and Mexico against the United States, occurred in March 1917. Mexico was proffered the reconquest of the American South-West for participation. Both Japan and Mexico denied knowledge of the note.

*The Presidential Campaign.*—During the year 1919 the power of Carranza was at its highest, though he was never supported by any really important part of the population. Adequate justification for his recognition in 1915 would have developed had he speedily pacified disturbed areas, consolidated his power on a civil instead of a military basis, and shown a reasonable attitude toward the United States. But pacification was retarded by inactivity of the military, which persisted in treating banditry as opportunity for self-enrichment. The new army, created to support the new Government, caused the downfall of the chief under whose sign-manual it pillaged the country. This military situation caused non-fulfilment of the promises of the Carranza revolution. There were many other contributing causes. The new constitution was not in force even within the controlled area. Its labour provisions were never carried out. The emancipation of the peon class was nullified by disturbed conditions. The financial state of the country left much to be desired, though

commerce grew, tax receipts were higher than under Díaz and metallic currency was in use. The educational system had been left largely in the hands of the states and municipalities, and only in a few places did it receive adequate financing and attention. The courts of justice were in deplorable condition; the jails were crowded with untried prisoners. Congress broke with the President in so far as it could, refusing to pass his initiatives and withdrawing many of his extraordinary powers. The city of Mexico, given rein as a "free municipality," was remiss in police regulation, sanitation, education, administration of justice and control of public morals. The President violated the ballot, imposing governors on many states and using them to further his intention to designate his successor. He arrested the partisans of Gen. Obregón, and imprisoned members of Congress who opposed him. In external affairs the non-payment of the interest on the national debt, doubtful neutrality, and nationalization of oil lands, with retroactive enforcement as it affected foreign investors, combined with indifference toward violence committed upon foreigners, cast odium upon the party in power. These attitudes and conditions are not entirely chargeable to Carranza or his party. Many of them typify inveterate evils. There had been improvement in many respects since the revolution began, and it seemed that continued betterment depended chiefly upon the peaceful transmission of the presidential power. The presidential campaign was waged for a year and a half; by the beginning of 1920 it was plain that Gen. Obregón had the support of the army, the people, especially of the radical groups, and of foreign investors. His rivals, Gen. Pablo González and Ignacio Bonillas, were then really eliminated, though they continued their campaigns.

*The Sonora Revolt.*—The President's determination to defeat Obregón led him in March to attempt to control the Government of Sonora, the candidate's home. The state officials, friends of Obregón, prepared to prevent this. To this end, a railway strike on the Southern Pacific of Mexico was planned and called. When Carranza threatened to operate the road with soldiers, to invade the state with his army though it was at peace, the state anticipated him on April 8, operating the road with strikers, whose terms were conceded. It also seized the public offices at Aguas Prietas, while the state Legislature voted (April 9) to secede until assured that the sovereignty of the state would not be infringed. Troops were raised to repel Federal invasion. General Obregón, summoned to Mexico City to answer charges of fomenting rebellion, escaped to the south-west and took the field. By the middle of April all the west coast was in revolt, and most of the northern states were disaffected. By the end of the month Mexico City was cut off from telegraphic communication with the world. The Liberal Constitutionalist party, as the insurgents called themselves, now demanded Carranza's resignation and set up Adolfo de la Huerta, Governor of Sonora, as provisional president under the terms of the Plan de Aguas Prietas, dated April 9 1920, which promised protection to foreigners, enforcement of legal rights, and development of commerce and industry. On the last day of April it was evident that Carranza was planning to desert the capital. More than 50,000 troops were against him, many of them at the gates of the city. Pablo González then joined the revolt, and his command of the south-east practically ended the power of the Government. On May 6 the exodus of the Federal Government for Vera Cruz began. Twenty-one trains were to carry 20,000 troops, carloads of records, and millions of treasure. The employees of the State, including the Cabinet, the Supreme Court and the Permanent Commission of Congress, were included. Misfortune attended every step. Attacks on the convoy began at once. On May 12 Gen. Guadalupe Sánchez, in control of the way to Vera Cruz, went over to Obregón; Cándido Aguilar, the President's son-in-law, in command at Orizaba, thus deserted, fled. Finally, after his trains were useless and his forces had been defeated at Aljibes, Carranza set out on horseback with a small remnant of followers for the Puebla mountains, in an attempt to escape to a Gulf port. While on his way he was betrayed and shot dead at night on May 21 in a mountain cabin at Tlaxcalantongo, Puebla.

*The New Government.*—Obregón, who had entered Mexico City May 8, had endeavoured to capture Carranza under reiterated assurances of personal guarantees. It was evidently the intention to spare his life. The dead chief and the wrecked expedition were brought back to the capital. On May 25 Adolfo de la Huerta was made substitute president by the reassembled Congress. As the active ally of Obregón, he initiated the policies of the new régime in company with radicals, who evinced attitudes toward foreign interests antithetical to the Carranza policies. Obregón was opposed in the Sept. elections only nominally by a Catholic candidate. His inauguration on Dec. 1 was attended by large delegations from the United States, including several governors of states, and by many American and European diplomats. During the closing months of 1920 there were occasional minor actions against rebels and bandits. Radical agitation among industrial workers seriously affected the country. The sympathy of the Provisional Government with labour unrest presaged difficulties accentuated by falling markets in Mexican staple products. Recognition by the Great Powers was still pending in Jan. 1922. Delay was due to the non-solution of the petroleum controversy and to Obregón's refusal to negotiate a treaty, demanded by the U.S. Government, guaranteeing protection to American lives and property. (H. I. P.)

**MEYER, GEORGE VON LENGERKE** (1858–1918), American diplomatist, was born in Boston, Mass., June 24 1858. After graduating from Harvard in 1879 he was engaged in business for 20 years. He entered public life in 1889 as a member of the Boston Common Council and two years later became a member of the Board of Aldermen. From 1892 to 1897 he was a member of the Mass. House of Representatives, being speaker for the last three years. In 1898 he was appointed by Governor Wolcott as chairman of the Mass. Paris Exposition Managers. From 1900 to 1904 he was a member of the Republican National Committee. In 1900 he was appointed ambassador to Italy by President McKinley, and five years later was transferred by President Roosevelt to Russia. In 1907 he was recalled by Roosevelt and made Postmaster-General in his Cabinet. From 1909 to 1913 he was Secretary of the Navy in President Taft's Cabinet. On the outbreak of the World War he urged preparedness and criticised America's naval administration. He was actively associated with the National Security League and the Navy League. He was a director in many organizations, including the Amoskeag Manufacturing Co., Old Colony Trust Co., Puget Sound Light & Power Co., Walter Baker Co., and Ames Plow Co. He died in Boston March 9 1918.

See M. A. De Wolfe Howe, *George von Lengerke Meyer: His Life and Services* (1920).

**MEYER, [MARIE] PAUL HYACINTHE** (1840–1917), French philologist (*see* 18.349), died at St. Mandé, near Paris, Sept. 8 1917.

**MIALL, LOUIS COMPTON** (1842–1921), English biologist, was born at Bradford Sept. 12 1842, the son of a Congregational minister. At the age of 15 he became a junior teacher in a Bradford school, and there began the study of natural history, subsequently attending the Leeds School of Medicine for more systematic biological training. His connexion with the discovery of a new labyrinthodont from the coal-seams near Bradford introduced him to Huxley, from whom he had much assistance. In 1871 he became curator of the museum of the Leeds Philosophical Society, of which he was already secretary, and in 1876 he was appointed the first professor of biology in the Yorkshire College, afterwards the university of Leeds. This post he held until 1907. In 1892 he was elected F.R.S. He was Fullerian professor of physiology in the Royal Institution in 1904–5. He presided over the zoölogical section of the British Association (1897) and the education section (1908). Though his earlier work was mainly geological and palaeontological, he eventually paid special attention to entomology (*see* 9.656, 13.429), laying much stress on the observation of living insects. He wrote a monograph (with Prof. A. Denny) on the cockroach in 1886, and also *Object Lessons from Nature* (1891); *Natural History of Aquatic Insects* (1895); *Round the Year* (1896); *Injurious and*

*Useful Insects* (1902); *House, Garden and Field* (1904); *The Early Naturalists* (1912). He died at Leeds Feb. 21 1921.

**MICHAELIS, GEORG** (1857– ), Prussian official, was born on Sept. 7 1857 at Haynau. He studied law and was for some years after 1885 a lecturer at the university of Tokyo. On his return to Germany he continued his official career and rose to the position of Under-Secretary of State in the Prussian Ministry of Finance. On the outbreak of the World War he was appointed director of the Imperial department for the control of the grain trade, and in Feb. 1017 State commissioner for the national food supply. On the retirement of Bethmann Hollweg in July 1917 the influence of the higher military authorities, including Hindenburg (in the leading strings of Ludendorff), was exercised in favour of the appointment of a chancellor who would accommodate his policy to theirs in home as well as in foreign affairs. In the hope of avoiding conflicts between the highest military and the highest civil authorities of the empire, the immediate entourage of the Emperor, in particular the chief of his Civil Cabinet, Valentini, seems to have suggested the appointment of a colourless Prussian official. Michaelis was accordingly appointed, but even in the first weeks of his chancellorship his weakness became manifest. The so-called Peace Resolution in favour of a peace "without annexation or indemnities" had been passed by the Reichstag on July 19. Michaelis was confronted with the demand of the parliamentary majority that in his public utterances he should identify himself with the spirit and the letter of this resolution. Under the influence of the military authorities he attempted to evade this obligation by declaring himself, in a phrase that became celebrated, the supporter of the resolution "as he understood it." There was a storm of indignation throughout the country, but Michaelis had still further to compromise himself, together with Adml. von Kapelle, over the naval mutiny before it was recognized that his position was altogether untenable. He was with some difficulty induced to resign, and was succeeded by Count Hertling on Nov. 1 1917. He was then appointed chief president in the province of Pomerania, an office which he held till 1919.

**MICHELER, JOSEPH ALFRED** (1861– ), French general, was born at Phalsbourg (Meurthe) on Sept. 23 1861. He entered St. Cyr in Oct. 1880 and was appointed a sub-lieutenant on the completion of his course in 1882. He was promoted lieutenant in 1886, captain in 1891, major in 1901 and lieutenant-colonel in 1909. Three years later he was made a colonel. At the outbreak of the World War he was employed as chief-of-staff to the VI. Corps. In Oct. 1914 he was promoted general of brigade, and in Jan. 1915 was transferred as chief-of-staff to the I. Army. On Aug. 3 1915 he took over command of the 53rd Inf. Div., being later (March 25 1916) promoted a temporary general of division and appointed to the XXXVIII. Army Corps. Ten days later he was placed at the head of the X. Army. On June 22 1916 he was confirmed in his rank as general of division. He commanded the X. Army during the battle of the Somme, and was then called to the head of a new group of armies formed behind the centre for the exploitation of the victory counted upon in Gen. Nivelle's Aisne scheme. He was thus involved very deeply in the controversies which centred upon that scheme both before and after April 16 1917. It was principally his criticisms that initiated the internal crisis, and led to the council of war, in which, however, he seems not to have followed up his objections. His relations were strained with his subordinate Mangin as well as with Nivelle, and the latter sought afterwards to saddle him with part of the responsibility for the relative failure of the offensive. His group of armies being broken up he returned to the duties of an army commander. In May 1918 he vacated the command of the V. Army which he had held for a year. He was made a commander of the Legion of Honour (Sept. 30 1916).

**MICHELHAM, HERBERT STERN, 1ST BARON** (1851–1919), British financier, was born Sept. 28 1851, the son of Hermann de Stern, Portuguese baron and banker, and Julia Goldsmid. He entered his father's banking house, Stern Bros., of London, Paris and Belgium, and inherited from his father the Portuguese barony and a fortune of £2,000,000, which was much increased by his own financial ability. In July 1905 he was created a baronet and in Dec. was raised to the peerage of the United Kingdom as Baron Michelham. He presented to the nation the quadriga surmounting the arch on Constitution Hill, and subscribed liberally for the purchase of pictures for the National Gallery, besides forming a valuable private collection. He was also well known as an owner of race-horses. During the World War he bought the Hotel Astoria in Paris for use as a British hospital, and established and maintained a convalescent home for officers at Cimiez. He died in Paris Jan. 7 1919 and was succeeded by his son Herman Alfred Stern, 2nd Baron (b. 1900).

**MICHELSON, ALBERT ABRAHAM** (1852– ), American physicist, was born in Strelno, Germany, Dec. 19 1852. His parents moved to San Francisco, Cal., where he studied in the public schools. He graduated from U.S. Naval Academy in 1873 and was instructor in physics and chemistry there during 1875–9. He was then for a short time in the *Nautical Almanac* office. From 1880 to 1882 he studied in Berlin, Heidelberg and Paris. He resigned from the navy in 1881. In 1883 he was appointed professor of physics at the Case School of Applied Science, Cleveland, O., and six years later accepted a similar position at Clark University. In 1892 he was appointed professor and head of the department of physics at the university of Chicago. He early directed his researches to the velocity of light and while in Cleveland invented his interferometer (*see* 14.693), which enabled him to measure distances by means of the length of light-waves. In 1892 he was a member of the Bureau Internationale des Poids et Mesures and in 1897 of the International Committee of Weights and Measures. He was made president of the American Physical Society in 1901 and of the American Society for the Advancement of Science in 1910. He received medals and prizes from many learned societies and in 1907 was awarded the Nobel Prize for physics. In 1920 he was able to demonstrate by means of light-interference that the diameter of Alpha Orionis was 260,000,000 miles. This was the first computation ever made of the size of a star. He was the author of numerous papers on light and in 1903 published *Light Waves and Their Uses*, being Lowell lectures for 1899. In 1921 he was awarded the gold medal of the Society of Arts, London. (For the "Michelson-Morley experiment," in interference of light, with its bearing on the Einstein theory, *see* RELATIVITY.)

**MICHIGAN** (*see* 18.371).—The pop. of Michigan in 1920 was 3,668,412, an increase of 30·5% within the decade. Of the total pop. 61·1% lived in places having at least 2,500 inhabitants, as compared with 47·2% in 1910. This increase in the urban percentage was greater than in any other state in the Union for the decade. The rural pop. underwent a slight actual decrease from 1,483,129 in 1910 to 1,426,852 in 1920.

*Education.*—In 1917 there were in the state 892,787 children of school age, of whom 633,020 were taught in public schools. In these, particularly in the secondary schools, vocational courses have been added in recent years. At the institutions of higher education attendance greatly increased, especially in 1919 and 1920. Some of the colleges with church connexions shared in this growth; but the chief enlargement has been at the university of Michigan (*see* MICHIGAN, UNIVERSITY OF) and the Michigan Agricultural College.

The pop. and rate of increase of the principal cities are shown in the following table:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Battle Creek | 36,164 | 25,267 | 43·1 |
| Bay City | 47,554 | 45,166 | 5·3 |
| Detroit | 993,739 | 465,766 | 113·4 |
| Flint | 91,599 | 38,550 | 137·6 |
| Grand Rapids | 137,634 | 112,571 | 22·3 |
| Hamtramck Village | 48,615 | 3,559 | 1,266·0 |
| Highland Park | 46,499 | 4,120 | 1,028·6 |
| Jackson | 48,374 | 31,433 | 53·9 |
| Kalamazoo | 48,858 | 39,437 | 23·9 |
| Lansing | 57,327 | 31,229 | 83·6 |
| Muskegon | 36,570 | 24,062 | 52·0 |
| Pontiac | 34,273 | 14,532 | 135·8 |
| Port Huron | 25,944 | 18,863 | 37·5 |
| Saginaw | 61,903 | 50,510 | 22·6 |

To add to the facilities for higher education, "junior colleges," with curricula covering two years of college work, have been established in Detroit, Grand Rapids, Muskegon, Pontiac and Highland Park, in connexion with their secondary-school systems.

*Agriculture.*—In 1910 there were 196,447 farms in Michigan, a decrease of 10,513, or 5·1%, as compared with 1910. During the decade all farm land increased from 18,940,614 ac. to 19,632,961 ac.; improved land increased from 12,832,078 ac. to 12,925,521 acres. During the same period the average acreage per farm increased from 91·5 to 96·9, and the average value of land per acre increased from $32.48 to $50.40.

The farming area of Michigan continues to be concentrated mainly in the southern part of the lower peninsula of the state. In the upper peninsula, farms comprise less than 10% of the land area. The area nominally in woodland, including farm woodlots as well as forests and cut-over lands, comprises nearly two-thirds of the surface of the state; but of this area not more than about 5,000,000 ac., nine-tenths of which lies in the upper peninsula, now bear timber worth cutting. Most of the rest has come to be stump lands, on which the recurrence of fires prevents any spontaneous reforestation. The barrenness of the sandy soil and the shortness of the growing-season have hindered the reduction of land to cultivation, and some 10,000,000 ac. (more than one-fourth of the total surface of the state) are thus a deforested desert. Several thousand acres of it revert to the state each year in default of taxes. These reverted tracts, comprising 566,850 ac. in 1918, are administered by the Public Domain Commission (created in 1915) with a view to the sale of such as can be used as agricultural homesteads and to the setting aside of the rest as forest reserves. These forest reserves, 145,035 ac. in 1920, are under state forest management for the prevention of fires and for systematic reforestation. In 1920 some 9,000 ac. had been replanted.

*Minerals.*—In mineral production no new resources of importance were developed during the decade 1910–20. The mining of iron ore has continued vigorously. The production of copper was pushed to the fullest capacity during the World War; but the severe decline of the market after the Armistice caused a sharp reduction of output. In contrast with its great prosperity in many preceding years, the Calumet & Hecla Co., the largest of the Michigan copper producers, experienced from its operations a loss of $652,286 in 1919 and $4,161,832 in 1920.

*Manufactures.*—The industrial survey of the U. S. census of 1920 was not yet available in Nov. 1921. The manufactured products in 1914 were valued at $1,086,162,432, as compared with $685,109,000 in 1909, an increase of 58·5% in five years. This advance was mainly due to the extraordinary growth of the automobile industry and its concentration in the state. The number of automobiles manufactured increased from 9,125 with a value of $7,996,534 in 1904 to 64,800 with a value of $96,651,451 in 1909 to 443,072 valued at $398,289,022 in 1914. In value this was 62·9% of the whole product of automobiles in the United States in 1914. In more recent years this industry has continued its rapid enlargement. It is estimated for the year 1920 that of the nearly 2,000,000 automobiles made in the United States more than two-thirds were produced in Michigan. The number of wage-earners engaged in the making of automobiles and their parts in 1914 was 67,538, constituting 24·9% of the total number of wage-earners in the state; and these were probably quadrupled in number and doubled in percentage by 1920. The sharp decline in the demand for automobiles near the end of 1920, however, caused the closing of so many factories that the proportion of labourers unemployed in Michigan exceeded that of any other state in the Union.

As the production of automobiles increased the making of horse-drawn vehicles diminished, from 174,889 carriages and 52,273 wagons in 1904 to 25,265 and 11,454 respectively in 1914. The value of timber products remained about stationary, $58,523,217 in 1914, and the product of flour and grist mills likewise. The output of furniture, leather, chemicals, beet sugar, paper and wood pulp substantially increased.

The 11 leading manufacturing centres in the order of the value of their products in 1914 were, Detroit, Flint, Grand Rapids, Lansing, Battle Creek, Kalamazoo, Saginaw, Jackson, Pontiac, Muskegon, and Bay City. Detroit (*see* DETROIT) maintained an easy primacy. Flint rose rapidly after 1904, standing second in 1914 by virtue of its automobile factories. The product of these and their ancillary foundries and machine shops comprised in 1914 more than nine-tenths of the total value of the city's manufactures. Lansing's rise from seventh to fourth place and Pontiac's great growth were likewise due to their automobile industries. Grand Rapids continued to be the focus of the American furniture industry, and Battle Creek maintained its predominance in cereal preparations.

*Finance.*—Appropriations by the Legislature, $5,929,306 in 1909, advanced steadily to $9,610,555 in 1915, and then much more rapidly to $17,432,512 in 1919. The volume of the general property tax, which comprised nearly all of the state's revenue, lagged behind the appropriations at the close of the decade 1910–20, and the prospect of a treasury deficit in 1921 caused the passage of a law for a tax on corporation franchises as an emergency recourse. This was expected to yield some $6,000,000 in the two years following.

*Legislation and Administration.*—Amendments added to the revised constitution of 1908 provided for popular initiative and referendum on constitutional amendments and in legislation (1913); for the recall of elected officials (1915); for prohibition (1916); for woman suffrage (adopted in 1917 after having been successively rejected in 1912 and 1913), and for the issue of state bonds to the amount of $50,000,000 for the improvement of highways (1917). The provisions for initiative, referendum and recall have as yet found little utilization, but the issue of highway bonds facilitated a marked improvement of roads. An increase of the licence charges on automobiles has also increased the road funds, the application of which is largely determined by an Act of the Legislature (1915) establishing a system of state trunk roads. Among other noteworthy enactments by the Legislature are the Judicature Act of 1915, consolidating and revising the laws of civil practice and procedure; the "blue sky" law of 1913 and the creation of the Michigan Securities Commission in 1915 to regulate the sale of securities; the provision for juvenile courts (1911); the creation of a board of mediation and conciliation to deal with labour disputes (1915); a department of state police (1919); and a budget commission (1919).

*The World War.*—Colonel Bersey, Adjutant General, estimated the number of men who entered the military or naval service from Michigan during the World War at 175,000 to 200,000, and the number who lost their lives at 3,200. The Government reports were not yet complete in Nov. 1921 and were not to include the many men from Michigan who served in the Polish, Canadian or other armies.

The following figures as to Michigan's participation in the Liberty Loans are taken from the official reports of the Loans and Currency Division of the Treasury Department, and differ slightly from the totals reported by the state bank commissioner, 1919:—

| Loans | Quota | Amount Subscribed | Accepted |
|---|---|---|---|
| First . . | $ 56,172,800 | $ 65,819,750 | $ 44,914,950 |
| Second . . | 82,550,000 | 115,530,550 | 104,380,500 |
| Third . . | 83,600,000 | 107,671,400 | 107,436,900 |
| Fourth . . | 152,400,000 | 177,349,000 | 176,102,700 |
| Fifth . . | 115,425,000 | 155,787,450 | 125,372,300 |

*Political History.*—Since 1910 there generally have been large Republican majorities in state and national elections, without appreciable representation of any other parties in the state Legislature. In the presidential election of 1912, however, Michigan gave its electoral vote to the Progressive ticket, and in 1912 and 1914 it elected a Democrat as governor. The governors of Michigan, 1911–21, were: Chase S. Osborn (Rep.), 1911–3; Woodbridge N. Ferris (Dem.), 1913–7; Albert E. Sleeper (Rep.), 1917–21; Alexander J. Groesbeck (Rep.), 1921– . In a conspicuous contest in 1918 Truman H. Newberry (Rep.) was elected to the U.S. Senate by a narrow majority over Henry Ford (Dem.). Charges of excessive expenditures in this campaign were brought against Senator Newberry and numerous associates, and they were convicted in the U.S. District Court (1920) and were sentenced to two years' imprisonment. The U.S. Supreme Court set aside the conviction May 2 1921; on Jan. 12 1922 the U.S. Senate decided by a vote of 46 to 41 that Newberry was entitled to his seat. (U. B. P.)

**MICHIGAN, UNIVERSITY OF** (*see* 18.378), was the first university established by an American state to become conspicuously successful. The promise of its earlier period continued in recent years. The total roll of the faculty increased from 350 in 1907–8 to 616 in 1919–20, while the number of students grew from 5,013 to 9,401 in the same period (5,007 in the college of Literature, Science and the Arts, 2,038 in the college of Engineering and Architecture, 394 in the Medical School, 382 in the Law School, 99 in the college of Pharmacy, 42 in the Homoeopathic Medical School, 350 in the college of Dental Surgery, 340 in the Graduate School, 1,961 in the Summer Session and 222 in the two training schools for nurses). On Jan. 1 1921 there were over 30,000 living graduates. The Medical School, Law School and Homoeopathic Medical School demand two years of college work before admitting students.

Among the buildings erected between 1910 and 1920 were the Hill Auditorium (1913) seating 5,000 persons, with remarkably good acoustic properties; the Natural Science Building (1916); the new University Library (1919) containing approximately 400,000 volumes, with room for over 1,000,000 volumes; the Michigan Union (1919), a student clubhouse costing $1,250,000, the gift of

some 14,000 alumni. A new university hospital was to be completed in 1922 with accommodation for 600 patients, affording proper facilities for the teaching of medicine, and the first hospital controlled exclusively for the benefit of the people of the state. Four dormitories for women students were also erected during this period.

The income of the university in 1919–20 was $3,802,164. Of this amount $1,687,500 was derived from the state through the tax of three-eighths of a mill on every dollar of taxable property, $38,428 from the state lands originally granted by the Government for the support of the university, $682,445 from tuition, student fees, etc., and $659,250 from special appropriations and savings for the erection of buildings.

Over 12,000 graduates and students of the university were enlisted in the U.S. forces during the World War, of whom 231 lost their lives. This number included 2,747 students who were enrolled in the collegiate section of the Students' Army Training Corps during the fall of 1918. Pres. James Burrill Angell, upon his resignation in 1909, was succeeded by Harry Burns Hutchins, dean of the Law School, as acting president (1909–10) and president (1910–20). Pres. Hutchins resigned in 1920 and was succeeded by Marion Leroy Burton, who had been president of Smith College (1910–7) and of the university of Minnesota (1917–20).

Cross, "The University of Michigan and the Training of her Students for the War," *Michigan History Magazine* (Lansing, Jan. 1920).

(W. B. S.)

**MIDLETON, WILLIAM ST. JOHN FREMANTLE BRODRICK,** 1ST EARL OF (1856– ), English politician (*see* 18.419), did not remain long out of Parliament after his defeat in the general election of 1906, as in the following year his father died, and he entered the House of Lords as 9th viscount. He took a considerable share in the work of that House, and played an active part behind the scenes in Unionist politics, without returning to ministerial office. He was indeed perhaps the most conspicuous figure among the Unionist leaders who did not find a place in Mr. Asquith's Coalition Cabinet. He had meanwhile become specially prominent as leader of the southern Unionists of Ireland, in virtue of his position as a landowner in county Cork. In his opposition to the Home Rule bills, he was never willing to base himself mainly on the difficulties of Ulster, but constantly called attention to the necessity of protecting loyalists in the South and securing them from discriminating taxation. He was disquieted by the negotiations carried on in the summer of 1916 with the Irish leaders by Mr. Lloyd George on behalf of Mr. Asquith's Coalition Ministry, on the basis of excluding the six Ulster counties but bringing the Home Rule Act at once into effect in the rest of Ireland. In the Irish Convention, which was set up in the middle of 1917 and sat into the following year, he and a band of southern Unionists separated themselves from the Ulster standpoint, and showed themselves ready to concede a unitary Home Rule Government for Ireland, subject to provisions for safeguarding the minority of loyalists. At the beginning of 1920 he was created an earl.

**MILK** (*see* 18.451, 7.737).—From time immemorial milk and milk products have been highly prized by man as a food, and Jewish, Egyptian, Greek and Roman literature contain numerous references to the use of milk and milk products. In earlier times the milk of nearly all the domestic animals was used for the food of man, and although at the present time the milk of the cow provides the main bulk of the world's dairy products, the milk from the ass, goat, mare, reindeer, camel, ewe, llama and zebra is still used in various parts of the world.

Milk consists of a watery intimate admixture of protein, fat, carbohydrate, and soluble inorganic constituents (the latter being usually referred to collectively as ash), the proportion and amount of these constituents varying according to the species from which they are derived. The principal protein of milk is casein, a protein not found elsewhere in the body, and belonging to a group of proteins called phosphoproteins owing to the presence of combined phosphorus in the protein. Other proteins are present, namely, lactoglobulin and lactalbumin.

It was formerly believed that the proteins of milk were identical with the proteins of blood serum, and that they found their way into the mammary secretion as a result of simple and direct transference from the blood stream. Recent chemical work on the structure of these proteins has not, however, confirmed this belief. Hartley (1914) analysed the proteins of serum by the method of Van Slyke; Crowther and Raistrick (1916) by the use of the same method analysed the corresponding proteins of milk and colostrum. Woodman (1921) investigated the optical behaviour of these proteins when dissolved in dilute alkali at a temperature of 37°C. The results of these investigations indicate clearly that whereas the globulins of serum, colostrum and milk are one and the same protein, yet serum albumin and lactalbumin are to be regarded as distinct chemical individuals. From this the conclusion must be drawn that a distinct mammary synthesis is necessary for lactalbumin as well as for caseinogen.

Fats occur in milk in the form of minute globules, there being millions present in each c.c. of milk. The average diameter of these globules varies from ·01 mm. to ·0016 mm. Milk fat differs from body fat in that it contains a relatively large amount of olein and also in the fact that considerable quantities of fatty acids of low molecular weight are present. It is upon the presence of the fatty acids in butter fat that one of the tests for the purity of butter fat depends. In addition to traces of other bodies, the milk fat carries with it varying amounts of colouring matter derived from the food eaten.

The carbohydrate present in milk consists of a sugar called lactose. This sugar is peculiar to milk, and it is owing to the fermentation of this sugar by bacteria with the formation of lactic acid that the souring of milk is due.

The table below gives the average composition of the milk of different mammals.

The differences shown in the table below indicate a very important fact—that the milk of the species is peculiarly adapted for the efficient nutrition of the young of that species. Especially is this the case with the inorganic constituents of the milk. It is this difference in composition that necessitates especial care in the use of cow's milk for the rearing of infants. Although the composition of milk varies considerably among individuals of the same species, the variation in the same individual is as a general rule very small, and, contrary to general opinion, is but slightly influenced by conditions of feeding.

*Origin of Milk and Development of Mammary Gland.*—The first sign of development of the mammary gland in the embryo is the formation of a slightly thickened ridge or line called the mammary ridge. This is a slight thickening of the epidermis extending from the inguinal region to the axilla. This thickening becomes intensified in the areas in which eventually the mammary glands are situated, and little bud-like outgrowths of the epithelium extend into the underlying connective tissue in these regions, forming the mammary ducts. These ducts give rise to the galactophorous or milk sinus and milk ducts, and eventually form the alveoli. The thickened epithelium forms the nipple, so that the fully developed mammary gland in the adult resembles a bunch of grapes bound together with fatty connective tissue.

At birth the mammary glands are alike in both sexes, and consist entirely of a few rudimentary ducts and nipple. During infancy very little growth takes place, although towards puberty considerable deposition of fat takes place in the female in the vicinity of the nipple. At puberty in the female a certain amount of growth takes place, and occasionally a few alveoli, or milk-producing sacs, are

| | Woman | Cow | Buffalo | Goat | Ewe | Mare | Ass | Reindeer | Whale |
|---|---|---|---|---|---|---|---|---|---|
| Water | 88·32 | 87·75 | 82·57 | 86·34 | 81·08 | 90·38 | 90·30 | 67·7 | 60·47 |
| Fat | 3·43 | 3·40 | 7·63 | 4·25 | 7·67 | 1·00 | 1·30 | 17·1 | 20·00 |
| Protein | 1·55 | 3·50 | 4·69 | 4·40 | 6·08 | 1·98 | 1·80 | 10·9 | 12·42 |
| Milk Sugar | 6·44 | 4·60 | 4·30 | 4·26 | 4·26 | 6·28 | 6·20 | 2·8 | 5·63 |
| Salts | 0·26 | 0·75 | 0·81 | 0·75 | 0·91 | 0·36 | 0·40 | 1·5 | 1·48 |
| | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 |
| Specific Gravity | 1·032 | 1·0315 | 1·033 | 1·033 | 1·038 | 1·034 | 1·033 | — | — |

formed. The development of the mammary glands after puberty varies considerably with the species. As a general rule, further development of the mammary gland is closely associated with the onset of pregnancy, although in some cases, as in the mare and bitch, the mammary glands occasionally develop to the milk-producing stage even in the absence of pregnancy. The development of the mammary gland and the secretion of milk are closely correlated with the formation and subsequent atrophy of a body called the corpus luteum. This body is found in the ovary as the result of the shedding of an egg cell or ovum, which, if fertilized, develops into the embryo or foetus. Provision is thus made for the adequate nutrition of the young animal after birth, and it is owing to this correlation between the development and atrophy of the corpus luteum and the development of the mammary glands that the mammary glands are enabled to secrete milk shortly after birth of the young.

The milk first secreted after the birth of the young is abnormal in appearance, and contains a large amount of albumin and globulin, together with a large number of cells. This first-produced milk is called colostrum or "biestings" and is generally used by the young calf. The change from colostrum to normal milk is gradual, generally taking about five days. The following table gives the chemical composition of colostrum and ordinary cow's milk:—

| | Colostrum | Milk |
|---|---|---|
| Water | 73·17 | 87·75 |
| Casein | 2·65 | 3·00 |
| Albumin } Globulin } | 16·56 | 0·50 |
| Fat | 3·54 | 3·40 |
| Milk Sugar | 3·00 | 4·60 |
| Ash | 1·18 | 0·75 |

Two views are held as to the manner in which milk is secreted. The first view holds that the cells of the alveolus enlarge, the enlarged end breaking off with its contents and forming milk, the lower half of the cell regenerating again and repeating the process. The second view is that milk is a true secretory fluid, the secretion from the cells being produced in the same way as in any other gland. Recent work tends to confirm the second view as being correct.

*Factors Influencing Milk Yield.*—The various causes which affect the yield of milk nearly always affect the percentage composition of its ingredients owing to the fact that the fat of milk is secreted independently of the other solids, and the various causes leading to alteration in yield affect only the water and solids, not the fat portion. Any factors therefore which alter the yield of milk will generally lead to variation in the percentage fat content. For this reason the variation in fat content of milk may range from 1·7 to 6·0 per cent. Under normal conditions, however, the percentage of fat present in milk is a breed characteristic, and the capacity to produce milk containing a high percentage of fat is an inherited characteristic. This fact has been utilized in Denmark to grade up the cow population, and by careful control of breeding allied with fat tests on the milk of milk-recorded cows, the average fat content of milk produced by cows in that country has been increased. The chief difficulty in carrying out the same grading-up process in England is due to the common practice of discarding bulls after a few years' use, the result being that the bull is killed before its real value as a milk-getter is known. The following table gives the average fat percentage of the various breeds of cows:—

| Breed | Fat Percentage | Breed | Fat Percentage |
|---|---|---|---|
| Jersey | 5·35 | Brown Swiss | 4·25 |
| Guernsey | 5·16 | Ayrshire | 3.66 |
| Devon | 4·60 | Holstein–Friesian | 3·42 |
| Shorthorn | 4·05 | | |

The various circumstances that affect the yield and composition of the milk of cows are as follow:—

(*a*) Period of Lactation.—The amount of milk secreted rises for the first two or three weeks after calving, then falls slightly for about six weeks. The rate of fall then gradually increases, accelerating greatly as the cow approaches the next calving period, until near calving the milk flow ceases altogether. In the case of cows not pregnant the milk flow may continue for as long as two years, and it is said that spaying greatly prolongs the period of yield. As the yield falls off, the fat percentage tends to increase.

(*b*) The Act of Milking.—Much of the milk obtained at a single milking is actually secreted at the time of milking. The first-drawn milk is generally poor in fat (it may be as low as 1%), and the percentage of fat rises gradually until in the strippings the fat content may be as high as 15 per cent.

(*c*) The Frequency of Milking.—The longer the interval between the milkings, the larger is the amount of milk secreted at each milking. This milk, however, is poorer in fat owing to the fact that the quantity of fat secreted at each milking is approximately the same, whereas the quantity of solids not fat and water secreted is dependent upon the interval between the milking. The pressure of the secreted milk in the udder inhibits the secretion of fat, and to a certain extent the secretion of solids not fat, so that a cow milked three times a day at equal periods will yield more milk relatively richer in fat than if milked twice a day.

(*d*) The Time of the Year.—A comparison of milk records, after allowing for effect of lactation period, will show that cows yield most milk in May and June and least in Nov. and December. The greater yield of milk in the spring months is undoubtedly correlated with the abundance of fresh green grass in the feed, and there appears little doubt that the yield of milk is partially dependent upon the palatabilty and succulence of the feed. For this reason, the practice among dairymen of giving wet mashes to cows is sound.

(*e*) Age of the Cow.—The yield of milk given in a lactation period increases up to the sixth lactation period, remains constant for the next two or three lactation periods and then declines.

(*f*) Other Conditions.—Carefully controlled experiments have shown that cows may perform a useful amount of muscular work without diminishing the milk yield to any serious extent, whereas the fat content may be actually increased.

The cow giving a fair yield of milk is producing large quantities of heat in excess of her requirements, and may therefore be subjected to fairly low temperatures without in any way decreasing her yield of milk or increasing her food requirements. In view of the tendency for extension in England of out-of-door cow-keeping, this fact is important. An accumulation of milk in the udder will cause an atrophy of some of the milk-secreting cells, leading to a decrease in the milk-yielding capacity which cannot be regained until the next lactation period. The same effect will be produced by long periods of under-feeding. For this reason it is extremely important that the udder should always be stripped at each milking, that the intervals of milking should be approximately equal, and that the cow should be adequately fed in proportion to her milk yield.

*Feeding in Relation to Milk Production.*—The magnitude of the dairying industry has directed the attention of research workers to the study of the relationship between milk yield and food requirement. It is obvious from a commercial standpoint that the establishment of such a relationship is the first important step towards the production of cheap clean milk. It is no exaggeration to say that the health of a nation is dependent largely upon an abundant supply of good cheap milk, and, to obtain this milk, production must be made profitable.

Under the auspices of the British Ministry of Agriculture the first essential step was taken by the introduction of milk-recording schemes. Under this scheme cows are ear-marked and the daily supply of milk yielded carefully weighed and recorded. In order to render the records accurate and of commercial value, surprise visits are made by official milk-recorders, who inspect the weighing of the milk, ear-marking and recording of the individual cows in a herd. The farmer who records his cows can thus obtain the annual record of the milk production of each of his cows, and this enables him to weed out of the herd the unprofitable cows. Before the World War it was established that, with cows yielding less than 600 gallons a year, milk could not be produced at a profit, and yet at that time the average milk yield for the country was well below this figure. In other words, the farming community was producing milk at a loss. The milk-recording of dairy cows is, therefore, the first important step towards the economical production of clean milk.

Having satisfactorily obtained the record of the individual yields of milk of cows, the next important item to consider is whether this milk is being produced at the minimum necessary expenditure of food material. Evidence has already shown that the herd giving the largest yield of milk does not necessarily produce the milk at the cheapest cost per gallon. It consequently becomes very important to investigate the possibility of feeding cows in such a way as to ensure the production of the milk with the least possible expenditure of food material.

This problem has been given increased attention since 1910, and, owing chiefly to the labours of keen men of science, has been satisfactorily solved. In this connexion brief mention may be made of Wolff, Lehmann, Kellner, Haecker, Savage, Armsby, Pott, Henry Morrison and their numerous co-workers, to whom our present knowledge on feeding standards is due.

In order to attack the problem, the first necessity was to establish the relative amounts of food material the animal retained for its own use. The chemical analysis of a feeding-stuff was of little value for this purpose, as the chemical analysis of a feeding-stuff, in the absence of any other data, gives no measure of the nutritive value.

The method adopted in order to assess the value of a feeding-stuff was to feed known weights of a given feeding-stuff to an animal, collect, weigh and analyse the excreta, whence by deduction the amounts of the feeding-stuff that were actually absorbed into the system, and were thus available for maintenance of bodily activity, growth, repair of tissues and other purposes, were obtained. The results of these somewhat tedious, patient researches are comprised in tables giving the chemical analyses of the chief feeding-stuffs and their digestible constituents, the most recent table of British figures being contained in *Miscellaneous Publication No. 32*, published by the Ministry of Agriculture.

This proved, however, only a partial solution of the problem, as it quickly became evident that the value of the digested nutrients varied according to the nature of the feeding-stuff from which these nutrients were derived. As a result of further research these difficulties were overcome, and a method was devised whereby it is possible to assess the true value of any given feeding-stuff for any required purpose. The chief facts discovered, stated briefly, are as follows:—

The value of a feeding-stuff may be divided into two portions: (*a*) its value as a supplier of protein; and (*b*) its value as a supplier of energy. The protein is required by the animal for the formation of flesh, the repair of waste tissue and the protein portion of milk; the energy is required for the maintenance of the bodily activities of the animal and the production of fat, milk, work and heat. A certain quantity of the digestible nutrients is required for maintaining the animal in health; this portion is generally called the maintenance requirement: the rest is available for the production of meat, work or any other purpose. The excess of protein beyond the animal's daily requirement is also available for the production of energy, but since the protein portion of a food is dearer than the non-protein portion, the use of protein as a source of energy is wasteful. Kellner, by a series of carefully controlled experiments, compared the relative values of digestible protein, fat and carbohydrate for the purpose of fat production. The method adopted was to adjust an animal's diet so that it neither gained nor lost weight, and then add a stated quantity of pure protein, fat or starch, to the diet and find the amount of fat produced. This gave a comparison between the fat-producing or energy-producing power of the various constituents of a food, and Kellner decided to express this energy value in the form of starch, which figure he called the "starch equivalent." Thus 1 part digestible protein was found to equal 0·94 parts starch, 1 part digestible fat 2·3 parts starch, and 1 part of digestible carbohydrate 1 part starch. This gave the necessary data for calculating the starch equivalent from any food-stuff, given the digestibility figures.

It was found on computation that the theoretical starch equivalent as computed differed from the actual values as found by experiment. This difference was due to the fact that the work of digestion of the feeding-stuffs varied considerably, and the energy thus required formed a prior charge on the digested nutrients, only a proportion of which was thus available for fat production. For this reason a "value number" was given to the different classes of feeding-stuffs, and this enables us with fair accuracy to compute the starch equivalent of a new feeding-stuff from the digestible nutrients.

Kellner's starch equivalent represents the fattening capacity of 100 lb. of a feeding-stuff expressed as starch. Thus 100 lb. of a feeding-stuff whose starch equivalent is 75 would produce as much work, fat or energy as 75 lb. of starch. Through this work, the problem of relating food requirement to milk production became simple.

An animal requires two essential substances, proteins for repair of tissues, and fat, protein or starchy material for energy. The average requirements of a cow for protein and energy for maintenance of bodily activity were ascertained and experiments soon established the relationship between gallons of milk produced and requirements of energy and protein. The results thus obtained form the basis of a scientific feeding standard for milch cows and are given in the following table:—

| Maintenance Ration | Digestible protein lb. | Starch equivalent lb. |
|---|---|---|
| A cow weighing 1,000 lb. requires | ·70 | 6·25 |
| A cow weighing 1,200 lb. requires | ·84 | 7·50 |
| A cow weighing 1,400 lb. requires | ·98 | 8·75 |

*Production Ration.*—In addition to the maintenance ration a cow will require approximately ·58 lb. of digestible protein and 2·50 lb. starch equivalent for every gallon of milk produced.

From the above table it will be quite easy to compute a suitable ration for a dairy cow giving a known quantity of milk. An example will suffice to illustrate the method.

Let us assume that a dairy cow weighing 1,200 lb. gives 3 gallons of milk, and that the foods available are mangolds, oat straw, linseed cake and palm-kernel cake. From a table of analyses similar to that given in the *Miscellaneous Publication No. 32*, already referred to, it is found in British practice that—

| | Digestible protein lb. | Starch equivalent lb. |
|---|---|---|
| 1 lb. oat straw contains | ·01 | ·17 |
| 1 lb. mangolds contains | ·005 | ·06 |
| 1 lb. linseed cake contains | ·24 | ·74 |
| 1 lb. palm-kernel cake | ·16 | ·75 |

| | Digestible protein lb. | Starch equivalent lb. |
|---|---|---|
| Now the maintenance requirements of a 1,200-lb. cow are | ·84 | 7·50 |
| 3 gallons of milk require | 1·74 | 7·50 |
| Total requirements of a 3-gallon cow = | 2·58 | 15·00 |

| A suitable ration would be:— | Digestible protein lb. | Starch equivalent lb. |
|---|---|---|
| 20 lb. oat straw | ·20 | 3·40 |
| 60 lb. mangolds | ·30 | 3·60 |
| 8 lb. palm-kernel cake | 1·28 | 6·00 |
| 3 lb. linseed cake | ·72 | 2·22 |
| | 2·50 | 15·22 |

The above ration would represent a suitable ration for a cow giving 3 gallons of milk a day on the limited foods available. It is possible by this method to feed the entire herd according to their actual milk yield. As a matter of practice, the whole of the herd are given the same maintenance ration, hay, roots and straw, and the cakes and meals are varied according to the milk yield. As a rough working rule it generally takes 3½ to 4 lb. of cake for every gallon of milk produced. The chief value in the scientific valuation of food requirement for a dairy herd lies, however, in the possibility of checking the adequacy of the actual ration fed to a herd and of enabling the computer to suggest a suitable alternative ration in cases where an unsuitable ration is being fed.

Much useful work in this direction is now being done in parts of England by agricultural organizers. The system adopted is for the farmer to fill up a food-record sheet, in which he enters the number of cows in the herd, the total milk produced and the actual weights of foods fed. From this the agricultural organizer computes the food value of the rations given and the scientific requirement. Comparison of the two sets of figures obtained enables him at once to state whether any alteration in feeding is necessary, and to suggest a possibly cheaper ration.

Other systems of feeding for dairy cows deserve mention here. A method based on the fat content of milk is in use in America. According to the Haecker-Savage standard, the food requirements are stated in digestible protein and total digestible nutrients, and the amounts to be added to the maintenance ration vary according to the fat content of the milk.

A system in common use in Denmark depends for its existence on its simplicity, a simplicity which has only been arrived at by sacrificing a certain amount of scientific accuracy. The Danish food-unit system consists of a table of equivalent values of various feeding-stuffs compared with a standard. The values arrived at have been based mainly on the extensive experiments carried out by Fjord and his co-workers with milch cows and swine. In Denmark the standard unit is 1 lb. of grain; in Sweden the standard unit is 1 kgm. (2·2 lb.) of mixed concentrates. A table is generally given showing the quantities of feeding-stuffs equivalent to one unit, and in computing rations all the feeding-stuffs are reduced to units. It is thus quite easy to ascertain the number of food units used to produce a gallon of milk, and enables quick and ready comparisons to be made between different cows or herds of cows. For this reason it has been greatly appreciated, and has proved of great value, especially in cooperative efforts to improve Danish dairy cattle and their feeding.

It is, however, only of value where the conditions ruling, both as to foods fed and to type of farming adopted, are similar, and the Danish food-unit system cannot be applied with safety to the variable conditions of English farming practice.

*The Hygiene of Milk Production.*—Milk, owing to its composition and liquid nature, forms an ideal medium for most bacteria, whether beneficial or otherwise. The rapidity with which bacteria will multiply in milk and the ease with which milk is contaminated when handled under ordinary conditions have impressed upon certain sections of the population the necessity of taking steps to improve the quality of the milk supply.

The American Medical Milk Commissions have already acted, and have reached general agreement as to the conditions under which milk should be marketed in the United States. The standards are based fundamentally on the bacterial content, and, similarly to the English custom, standards also exist as to fat content and total milk solids. Four grades of milk are recog-

nized. The highest grade is known as "certified" and is produced and marketed under very strict hygienic conditions. The price of production under these conditions is so high as to be out of reach of the general public, and three other grades of milk are recognized, Grade A, Grade B and Grade C. Grade A contains not more than 60,000 bacteria per c.c.; Grade B not more than 200,000 per c.c.; Grade C has no bacterial standard, but must be delivered within 48 hours of milking.

As the result of the grading of milk, very elaborate arrangements exist in America for rapid transit, efficient storage and hygienic manipulation, and it is certain that milk reaches the American consumer in a far cleaner condition than it does the English consumer.

There is undoubtedly need in England for more efficient regulation and control of milk from the dairy to the consumer's table, but much can be done by the observation of simple hygienic rules in the cow-shed or milk-shed. Fifty per cent of the bacterial contamination of milk occurs before it leaves the farmer's hands; the elimination of most of this 50% is a comparatively inexpensive matter. There is but little doubt that the bacterial count forms a very reliable indication of the care with which milk is produced and marketed, but, under present conditions, it unfortunately does not distinguish between the beneficial and the dangerous types of bacteria. It is consequently a matter of comfort to all, and a source of material satisfaction to many, that pasteurization kills all the bacteria in milk likely to prove harmful to the consumer. (E. T. H.)

**MILL, HUGH ROBERT** (1861– ), British geographer and meteorologist, was born at Thurso May 28 1861, and was educated at Edinburgh University. In 1884 he was appointed chemist and physicist to the Scottish marine station, and in 1887 became a lecturer for the university extension movement, being at the same time (1893–9) recorder of the geographical section of the British Association. He was president of this section in 1901. In 1892 he succeeded Dr. John Scott Keltie as librarian to the Royal Geographical Society and from 1902 to 1906 was hon. secretary of the Royal Meteorological Society, becoming its president in 1907. Dr. Mill served on many committees connected with meteorology and allied subjects, including the International Council for the study of the sea (1901–8), and the Board of Trade committee on the water power of the British Isles (1918). On the death of Mr. G. J. Symons he became (1901) director of the British Rainfall Organization, and editor of *British Rainfall* and *Symons's Meteorological Magazine*, and when the organization was converted into a trust in 1910 he became chairman of trustees, a position from which he retired in 1919. From 1906 to 1919 he was rainfall expert to the Metropolitan Water Board. Dr. Mill received many honours from learned societies, including the Victoria medal of the Royal Geographical Society (1915), and the Symons medal of the Meteorological Society (1918).

His chief works are *The Realm of Nature* (1892; latest ed. 1913); *The English Lakes* (1895); *Hints on the Choice of Geographical Books* (1897); *New Lands* (1900); *The Siege of the South Pole* (1905) and a historical introduction to Sir Ernest Shackleton's *Heart of the Antarctic* (1909). He also edited *International Geography* (1911).

**MILLER, JOAQUIN** (1841–1913), American poet (*see* 18.464), died at Oakland, Cal., Feb. 17 1913.

**MILLERAND, ALEXANDRE** (1859– ), French statesman, (*see* 18.465), was included in the Briand Ministry of July 1909 with the portfolio of Public Works, and in the Poincaré Ministry of Jan. 1912 he became Minister of War. He resumed this portfolio when, immediately after the outbreak of war in 1914, the Prime Minister, Viviani, desired to strengthen his team. He was Minister of War during the most difficult period when, after the first battle of the Marne, the Government had to have recourse to all sorts of improvisations in order to make good the deficiencies revealed in the country's military equipment. His administration was severely criticised by Clemenceau on account of the muddle and mismanagement which ruled the army medical services. He was also criticised with some vehemence for the delays in producing the right kind of shell and gun in adequate quantities. His extremely dogged character enabled him to withstand the many parliamentary attacks made upon his political position, and his departure from the War Office only took place when Delcassé's resignation brought about that of the whole Viviani Ministry in 1915. For the rest of the war he devoted himself to relief work, and went back to his very large practice at the bar. After the Armistice M. Clemenceau appointed him to the posts of Commissioner-General of the Republic at Strasbourg and Administrator of Alsace-Lorraine. These posts he filled with great distinction and ability. In the elections of 1919 he played the chief part in constituting the national *bloc* with which the moderate parties successfully fought the elections. When Clemenceau resigned Millerand formed the new Government. He was called upon to play a big part in the protracted inter-Allied negotiations with regard to the application of the Treaty of Versailles. His political prestige grew steadily during office, and when M. Deschanel was forced to resign the presidency of the republic he succeeded him as President, being elected by 695 votes out of 892 on Sept. 23 1920.

**MILLET, FRANCIS DAVIS** (1846–1912), American painter (*see* 18.466), died in the "Titanic" disaster at sea April 15 1912.

**MILLS, ROGER QUARLES** (1832–1911), American legislator (*see* 18.475), died at Corsicana, Tex., Sept. 2 1911.

**MILNE, SIR GEORGE FREDERICK** (1866– ), British general, was born Nov. 5 1866 and joined the Royal Artillery in 1885. He served in the Nile Expedition of 1898, and on the staff in S. Africa throughout the war of 1899–1902, for which he was promoted brevet lieutenant-colonel and given the D.S.O. He was afterwards almost continuously on the staff until 1913, and was promoted colonel in 1905. In 1913 he became commander of the artillery of the 4th Div., with which he went out to France in 1914. He was soon promoted major-general for distinguished service, and after some months on the staff on the western front was given, in July 1915, command of the 27th Div. which, three months later, he took out to the Salonika theatre. At the end of the year he was placed in charge of an army corps there. In May 1916 Milne, who had been given the K.C.B. for his services, was advanced to the command of the British forces in Macedonia, and he occupied this responsible position under the orders of three successive French commanders-in-chief until the end of the struggle. Little progress was made during the ensuing two years, the situation scarcely lending itself to the prosecution of effectual offensive operations, and the British military authorities at home being throughout opposed to the using-up of resources in this theatre. Milne, however, filled a difficult position with unfailing tact and sound judgment, and, when a general advance at last took place in the autumn of 1918 after Bulgarian powers of resistance had become spent, the forces under his personal command contributed appreciably to the bringing about of the final victory. He had been promoted lieutenant-general in 1917 and he was, on conclusion of hostilities, given the G.C.M.G. He remained in charge of the British forces in the Near East and about the Black Sea until 1920, and his services received further recognition in 1919 by his being promoted full general.

**MILNE, JOHN** (1850–1913), British seismologist and mining engineer, was born at Liverpool Dec. 30 1850, and was educated at King's College, London, afterwards studying at the Royal School of Mines. He then worked as a mining engineer in Newfoundland and Labrador, and in 1874 went as geologist with Dr. Bekc's expedition to north-western Arabia. In 1875 he was appointed professor of geology and mining in the Imperial Engineering College at Tokyo, and for nearly 20 years made his home in Japan, marrying a Japanese lady. Prof. Milne made a special study of seismology (*see* 8.817, 819, 820), and was recognized as the first authority on the subject. He travelled widely in the East in pursuit of his researches, and about 1880 established the seismic survey of Japan, with 968 stations. He also invented or perfected various forms of seismograph. In 1894 his books and instruments were destroyed by fire, and he returned to England, settling at Shide, I. of Wight, where he established an observing station. During the ensuing years he was largely responsible for the establishment of seismological stations throughout the world, in connexion with his work as secretary of the seismological committee of the British Association. He published two standard works, *Earthquakes* (1883) and *Seismology* (1898), besides books on scientific mining and crystallography and many papers in scientific journals. He died at Shide July 30 1913.

**MILNER, ALFRED MILNER,** VISCOUNT (1854– ), British statesman (*see* 18.476). After Lord Milner's return from South Africa he occupied himself mainly with business interests in the City of London. But, though he took up a somewhat detached attitude with regard to ordinary domestic politics, he was active on behalf of causes which appealed to him from the imperial side; and he made several speeches in different parts of the country in the next few years on behalf of Tariff Reform and Colonial Preference. He paid a visit to Canada, where he himself and his gospel of imperialism were well received. He was roused, however, by Mr. Lloyd George's budget of 1909, and he advised the House of Lords to reject the Finance bill, and, as he said at Glasgow, to "damn the consequences." He made several speeches in the next twelve months in defence of the Lords' position; and when the Parliament bill came up to the House of Lords in 1911, he was a leading spirit among the "Die-hards" who advised resistance to the end. He did not take a very prominent part in the opposition to the Irish Home Rule bill; but he aptly decribed the state of affairs in Ireland in the early summer of 1914 as "smouldering war," and he urged the remodelling of the Amending bill so as to reassure the Ulstermen.

The World War confirmed all his fears as to the disadvantages under which Great Britain and the Empire would labour during hostilities through the practice of unlimited Free Trade by the mother country for over half a century. He gladly accepted in the summer of 1915 the chairmanship of a committee of technical experts and practical agriculturists, appointed by Lord Selborne as President of the Board of Agriculture, to consider the means of maintaining and increasing food production in England and Wales. The committee reported that farmers should be encouraged to grow more wheat by a guaranteed minimum of 45s. a quarter for the four years following the harvest of 1916. Mr. Asquith's Coalition Government did not think the situation serious enough for this drastic remedy—shrinking here, as in other matters, from a bold decision. Lord Milner became critical of this "wait and see" attitude; and especially reprobated on several occasions the policy of concealing disagreeable facts. "Truth all around," he said at Canterbury on Oct. 30, "is the most fortifying thing in the world"; Englishmen could not brace their nerves and steel their hearts to win through by emulating the ostrich. Similarly he endeavoured, in April 1916, to spur on doubting ministers to accept the policy, which the country demanded, of universal compulsory service.

Mr. Lloyd George, when he formed his Ministry in the following Dec., at once turned to this resolute statesman, the only British administrator who before 1914 had directed a war from the civil side, and constituted him one of his principal colleagues in his War Cabinet of four (or five including Mr. Bonar Law). Considering the attitude of the two men at the time of the South African War, the offer and acceptance argued magnanimity on both sides. From this time to the cessation of hostilities their relations were close, and, after Mr. Lloyd George, Lord Milner took the largest share in the civilian conduct of the war. In vigour, resolution and readiness to take responsibility they resembled each other; but Lord Milner's experience, scholarship, steadiness and somewhat bureaucratic habit of mind supplied an invaluable complement to his chief's daring, impatience of precedent, quickness of apprehension and intellectual agility. In Feb. 1917 he attended, on behalf of the British Government, a conference of the Allies in Petrograd, the object of which was to improve the coördination in the prosecution of the war between the Government of the Tsar and the Western Powers; and he does not seem to have at all realized that Russia was on the brink of a revolution. He devoted himself closely to his duties in the War Cabinet, never making speeches in the country, and seldom in the House of Lords, where his appearances were mostly in explanation and defence of the policy of the Government in regard to food production and control. In June 1917 he announced that ministers had added between 70,000 and 80,000 men to the people available for agricultural work. In Feb. 1918 he vigorously defended Lord Rhondda's administration at the Food Ministry against ignorant criticism, and said that in regard to food Britain was in a better position than any other country except the United States. Except for what was necessary for the conduct of the war, everything must give way to food supply. The Corn Production bill of 1917 and the acceptance by the Government of the principle of Imperial Preference, and of the conservation of the raw materials of the empire, must have owed much to his influence and support. He worked heartily for inter-Allied coördination in the conduct of the war, and with Mr. Lloyd George attended meetings of the Supreme War Council at Versailles. He was in France at the time of the victorious German advance in the last ten days of March 1918; and it was largely owing to his influence that Gen. Foch was appointed Generalissimo of the Allied forces in France. It being vital to have a man of unusual capacity and vigour at the War Office in this critical spring of 1918, he was given the seals of Secretary of State for War on April 19; and it was he who presided over the Army Council during the succeeding months of the year which ended with victory.

In the reconstruction of the Ministry after the general election, Lord Milner left the War Office and became Colonial Secretary, a position for which his lifelong interest in the Empire peculiarly qualified him. In that capacity he attended the Paris Peace Conference as one of the British plenipotentiaries, and was a signatory of the Treaty of Versailles; and he subsequently helped to deal with a number of difficult questions arising under the Treaty out of the disposal of the German colonies conquered in war. But his colleagues utilized his services also in other directions. His financial authority was invoked to defend ministerial finance in the House of Lords; and when a serious revolutionary outbreak took place in Egypt in 1919, he was sent there, as the author of *England in Egypt*, at the head of a special mission to inquire into the causes, and to report on the form of constitution best calculated to promote Egyptian peace and prosperity. The mission arrived at Cairo in Dec. and remained till March; then in the summer of 1920 Lord Milner and his colleagues had long conferences with Zaghlul Pasha, the leader of the Nationalists, in London; and ultimately in Nov. they issued a memorandum recommending the recognition of Egyptian independence. Great Britain was to guarantee the integrity of Egypt against aggression; she would have a privileged position in Egypt and would maintain a garrison in the canal zone. The Capitulations were to be abolished, and the veto on legislation affecting foreigners would be vested in the High Commissioner. The new constitution, of which these were to be the principal features, had not yet been accepted when Lord Milner, who had only accepted office because of the national need, resigned in Feb. 1921, and his great services were fittingly recognized by the Order of the Garter. Before the end of the month he married Lady Edward Cecil, the widow of Lord Edward Cecil, formerly Miss Violet Maxse. (G. E. B.)

**MILOVANOVIĆ, MILOVAN G.** (1863–1912), Serbian statesman and diplomatist, was born at Belgrade on March 2 1863, and was educated there and in Paris, where he was the first Serb to take his degree as Doctor of Law and was awarded a gold medal for his thesis. On returning home he was appointed professor of international law at Belgrade University and soon acquired the position of one of Serbia's leading jurists. He was mainly responsible for drafting the new Serbian constitution of 1888; and, becoming secretary of the central committee of the Radical party, he entered politics and held successively the portfolios of Justice, Commerce, and Finance during the closing decade of last century. In 1901, at the request of King Alexander, he went to Rome as minister, and retained his post after the revolution of 1903. In 1907 he represented Serbia at the Second Hague Conference, and, in virtue of the proposals put forward by him, was appointed a member of the international court of arbitration. In July 1908 he was made Foreign Minister in the Vetimirović Cabinet, and thus had to guide Serbian policy through the difficult period of the Bosnian annexation crisis. The series of visits which he paid to the chief European capitals during the early winter insured due consideration for the Serbian standpoint and at the same time helped to calm down the inflamed sentiments of

Belgrade. In Berlin he was not received by the Imperial Chancellor, Prince Bülow; in London he was given friendly but discouraging advice by Sir Edward Grey, and on his return devoted his whole influence to restraining the war fever and sweetening the pill of Serbia's inevitable surrender to Austria-Hungary and her German ally "in shining armour." In 1910 he succeeded Pašić as Premier, and, being less of a party man than his old Radical colleagues, was able to bridge many gaps, and to acquire within a short space of time an unique position among the politicians of Serbia. Even in foreign politics he showed signal moderation, and though a confirmed Russophil, initiated negotiations for a commercial treaty with Austria-Hungary and actively favoured good relations with Turkey. Indeed the Balkan League, of which he was one of the chief founders, was originally conceived by him on much wider lines than events forced it to assume: the adhesion of Turkey and Rumania as well as the Slavonic States and Greece was to have given the League as a whole such a standing in Europe as would have rendered it immune from foreign dictation and interference. The decisive step towards the creation of the League was taken at a meeting between Milovanović and the Bulgarian Premier, Gešov, on Oct. 11 1911. Secret negotiations continued throughout the winter and led to the conclusion of the Serbo-Bulgarian Treaty of March 13 1912 (*see* SERBIA). Discussions were still pending between the various Balkan capitals for a more precise and comprehensive project of alliance when, on July 1 1912, Dr. Milovanović died suddenly of heart failure, in his 50th year. His removal at so critical a juncture was a grave blow to the cause of peace and moderation, and also deprived Serbia of her ablest statesman since the death of Prince Michael. Dr. Milovanović was married to a Rumanian lady, but left no family. He was the author of various books on law and politics and of a diplomatic study on the partitions of Poland.

**MILYUKOV, PAUL NIKOLAYEVICH** (1859– ), Russian politician and historian, was born in 1859. He studied history and humanities at the university of Moscow, was expelled for taking part in students' riots, but was readmitted and allowed to take his degree. He specialized in the study of Russian history and received the degree of Master in History for a learned work on the *State Economics of Russia in the First Quarter of the 18th Century*. He lectured with great success at the university and at a training institute for girl teachers; these lectures were afterwards expanded by him in his book *Outlines of Russian Culture* (3 vols., translated into German). He also started an association for "home university reading," and, as its first president, edited the first volume of its programme, which was widely read in Russian intellectual circles. His liberal opinions brought him into conflict with the educational authorities, and he was dismissed in 1894 after one of the ever-recurrent university "riots." He was even imprisoned for some time as a political agitator. When liberated he went to Bulgaria, and was appointed professor in the university of Sofia, where he lectured in Bulgarian with great success. He delivered also interesting courses of lectures in the United States—at summer sessions in Chicago and later on the Lowell lectures in Boston. *Russia and Its Crisis* presents a condensed report of one of these courses.

In 1905 the meetings of the Zemstvos which gave expression to the public indignation against the Government brought him back to Russia. He became the political editor of an important liberal paper, the *Retch*, and took an active part in the formation of the Constitutional Democratic party (Cadets), which aimed at political freedom and at a constitution on advanced democratic lines, based on universal suffrage. Milyukov became the leader of that party and had a great influence on the course of events in 1906, although he was not elected a member either of the first or of the second Duma. When the Tsar dissolved the first Duma he was one of the principal prompters of the "Viborg Manifesto," in which the members of the assembly declared themselves ready to follow the people in resisting arbitrary rule. This ill-conceived pronouncement ended in complete fiasco, and disqualified its signatories from participation in political elections. Milyukov had not signed as he was not a member of the Duma, and remained free from the persecution which set in with the Stolypin reaction. He was elected to the third and the fourth Duma, and played the part of a leader of the opposition, systematically criticising the policy of the Government and the attempts at compromise on the part of the Octobrists. In the fourth Duma, however, he was in favour of a progressive block, in which liberal Octobrists took a share, as this rendered the action of the Duma more effective. When the World War broke out he stood squarely for a policy of national union and active coöperation with the Entente, but the ineptitude and corruption of the War Office and of the Court drove him into an attitude of increasing hostility. On Nov. 1 1916 he delivered in the Duma a famous speech in which he asked pointedly, in connection with Sturmer's muddle: "Is it stupidity or is it treason?" His conduct at that time was characteristic of the state of mind of advanced Liberals—they were so disgusted at the misgovernment of the Sturmers, Protopopovs and Galitzins that they were unable and unwilling to make a stand against the growing discontent of the masses. They thought and said: "We must win the war, but it is impossible to win the war with these people at the head."

When the revolt of the troops broke the back of the old régime Milyukov took office in Prince Lvov's Provisional Government as Minister of Foreign Affairs. In a speech delivered to a revolutionary mob in the Taurida Palace he proclaimed his preference for a constitutional monarchy. His hope was that Nicholas II. would abdicate in favour of his son and the Grand Duke Michael Alexandrovich would consent to act as Regent for his nephew. This plan came to nothing on account of the unwillingness of Nicholas II. to part with his son. Milyukov strongly disapproved of Kerensky's policy and of the demagogic weakness of the parties in power—the social revolutionaries and Mensheviks. He would have hailed a restoration of discipline in the army and an energetic resumption of the war on the side of the Allies, but there was no basis for such a reconstruction at a time of revolutionary intoxication. When the Bolsheviks seized power he escaped to Kiev and lived there for some time under the rule of Skoropadsky, the German-appointed Hetman of the Ukraine. In this atmosphere, saturated by German influence, he gave up the cause of the Allies as lost, and began to speculate on the possibility of rebuilding the Russian State with the help of the Kaiser. He had conversations on the subject with von Munn, the German envoy in Kiev, and advised his fellow Cadets in the same sense. The majority of the latter were, however, firmly opposed to any pact with the arch-enemy of Russia, and the turnover on the western front put an end to these plans. After the Armistice Milyukov went to London and subsequently to Paris, where in 1921 he was directing a journal (*Last News*) in which he advocated an alliance with patriotic Socialists. (P. VI.)

**MINCHIN, EDWARD ALFRED** (1866–1915), English biologist, was born at Weston-super-Mare in 1866, and educated at Westward-Ho and Keble College, Oxford. He became a fellow of Merton College in 1893, and Radcliffe travelling fellow the same year. From 1890 to 1899 he was demonstrator of comparative anatomy at Oxford, and from 1899 to 1906 he held a similar chair at University College, London, being next elected professor of proto-zoölogy to the university of London. He published several works on the protozoa, especially sponges (*see* 25.716), and translated Bütschli's *Protoplasm* in 1894. He died at Selsey, Sussex, Sept. 30 1915.

**MINERALOGY** (*see* 18.509).—During the war period of 1914–8 much attention was given in all countries to the development of home resources of various minerals of economic value, and to meet new circumstances new sources of supply were developed. Further, there was an increased demand for certain kinds of minerals, for example those which yield the rarer metals used in the hardening of steel. Much of the mineralogical literature of the period has therefore been of an economic character, *e.g.* a long series of "Special Reports on the Mineral Resources of Great Britain" has been issued by the Geological Survey; and many recent text-books give prominence to the practical uses of

minerals. Fortunately, however, pure science has not been altogether neglected. Many new facts have been recorded, and new methods of investigation have been devised. A review of the recent scientific literature is given in the Mineralogical Society's series of "Mineralogical Abstracts."

*X Rays and Crystal-Structure.*—The new X-ray method of investigating the internal structure of crystals has been applied with much success to the study of minerals (*see* CRYSTALLOGRAPHY). The material for examination has usually been prepared as definitely orientated crystal plates, but it is now found that results can be obtained with a fine powder, *i.e.* an aggregate of minute crystals or fragments of crystals with all possible orientations. The method can therefore be used for the purpose of distinguishing between the crystalline and the amorphous or colloidal states. Stress has recently been laid on the importance of the colloidal forms of minerals, and some authors have separated these as distinct species, to which special names have been applied, from the corresponding crystalline forms possessing the same chemical composition. It has, however, not hitherto been possible, by optical means alone, to distinguish with certainty a colloidal form from a microcrystalline mineral which is opaque or which is cubic in crystallization.

*Microscopical Examination of Opaque Minerals.*—A new method for the investigation of opaque minerals has recently been borrowed from metallography, in which polished sections are examined under the microscope in reflected light. This method has proved to be especially useful for the study of metallic ores, and it consequently finds an economic application in the valuation of ore-deposits. The several mineral-species of which the ore is composed can be distinguished, and their relations to one another determined; *e.g.* the order of their deposition, and whether they are of primary or secondary origin. The technique of the subject (called mineralography or mineragraphy) is dealt with in the recent text-books of J. Murdoch, *Microscopical Determination of Opaque Minerals* (New York, 1916) and of W. M. Davy and C. M. Farnham, *Microscopic Examination of the Ore Minerals* (New York, 1920). The process of grinding and polishing the sections presents certain difficulties owing to the extreme differences of hardness of the several minerals that may be present. The prepared section is illuminated vertically by means of a right-angle prism placed in the tube of the microscope above the objective. Details of structure can be brought out by etching the section with various chemical reagents. The various characters (colour, hardness, relief) of the minerals, together with their behaviour towards reagents, help in their determination. But in many cases ordinary simple tests made on fragments detached from the polished surface are more reliable. Electrical tests can be made with quite simple apparatus: for example, the electrical conductivity can be determined with a dry cell and voltmeter using needles as terminals on the polished surface. Certain optical determinations can also be made in reflected polarized light; but whilst the use of polarized light is of prime importance for the examination of transparent minerals (*e.g.* in thin slices of rocks), it has only a limited application in the case of opaque minerals. It is, however, possible to determine whether a crystal is isotropic or anisotropic, and in the latter case to determine the directions of the principal axes of refringence and of absorption.

One result of this study of opaque minerals is to draw attention to the extremely intimate association and intergrowth of many of the ore-minerals; this is well shown in the numerous photomicrographs published by American workers in economic geology. What to all appearances by ordinary methods is a homogeneous mineral may be found by the new method to be really heterogeneous; and, in fact, several supposed mineral-species have been proved to be mixtures, and well-developed crystals have in certain cases been found to contain enclosures of other minerals. The method is thus of use for ascertaining the degree of purity of material collected for exact chemical analysis when the formula of a species is to be established. The long-debated question as to how silver exists in argentiferous galena (lead-ore) has been studied by this method. Galena containing 0·10 to 0·35 % of silver shows definite spots of tetrahedrite and argentite, whilst specimens containing more silver show evidence of later addition of proustite or pyrargyrite in the form of veinlets.

*Mineral Transformations.*—In synthetical mineralogy a large amount of experimental work has been done, more especially in the Geophysical Laboratory of the Carnegie Institution at Washington. Many minerals and allied compounds have been prepared artificially in silicate and salt fusions. The conditions necessary for their formation and their ranges of stability—either when alone or when in the presence of other compounds—have been studied in detail. One important result obtained by experimenting over wide ranges of temperature has been to show that practically all compounds known as minerals exist in several polymorphous forms. A long-known example of this is given by the three minerals andalusite, fibrolite and kyanite, all of which are composed of aluminium silicate ($Al_2SiO_5$), but which differ from one another in crystalline form and physical characters. Recent work has shown that silica ($SiO_2$) undergoes a remarkable series of changes in its crystalline structure and physical characters when it is submitted to different degrees of temperature. The changes with increasing temperature are:—

α-quartz (tetartohedral hexagonal), passing at 575° C. into
β-quartz (hemihedral hexagonal), passing at 870° C. into
β-tridymite (holohedral hexagonal), passing at 1,470° C. into
β-cristobalite (cubic) melting at 1,625° C.

These transformations are reversible, but with falling temperature they take place very slowly. Molten silica unless cooled very slowly solidifies as a glass. β-tridymite when quickly cooled undergoes a change at 163° C. ($\beta_2$-tridymite to $\beta_1$-tridymite), and at 117° C. passes over into α-tridymite, which is optically biaxial and probably orthorhombic in crystallization, being identical with the naturally occurring tridymite. Similarly, β-cristobalite when quickly cooled changes at about 180°–270° C. into α-cristobalite, which is optically biaxial (pseudo-cubic) and identical with the cristobalite occasionally found in volcanic rocks.

Now these and many other similar changes give information as to the conditions of temperature under which various minerals were formed in nature, thus providing a "geological thermometer." For example, the presence of tridymite, or of pseudomorphs of the more stable quartz after tridymite, establishes that the rock in which they occur must have been formed at a temperature between 870° and 1,470° C. The quartz of certain veins and that of granite present differences in structure which indicate that the former was formed below 575° C. and the latter above this temperature. Or, again, the presence of orthorhombic copper-glance (β-$Cu_2S$) as a pseudomorph after cubic α-$Cu_2S$ proves that the ore-deposit in which it occurs was formed at a temperature higher than 91° C.

*Chemical Composition.*—The chemical composition of many minerals is still imperfectly understood, and even for some quite common species there are doubts as to the correct empirical formulae. This is especially the case in the large division of the silicates, a satisfactory classification of which is still wanting. Many attempts have within recent years been made to gain some idea as to the constitution of the silicates; there has been much experimental work and plenty of speculation, but with no very definite results. In certain groups, *e.g.* the felspars and the garnets, the composition can be satisfactorily expressed on the assumption of the isomorphous mixing of different chemical molecules. But attempts to extend this principle to all silicates often lead to highly complex hypothetical molecules, the existence of which can only be regarded as doubtful. Alternative suggestions have been put forward, such as the "mass effect" of large molecules and the "solid solution" of certain other substances in the main mass of the crystal. Experiments with silicate fusions show that various substances can be taken up, or dissolved, in certain amounts, giving on solidification apparently homogeneous crystals.

As an example, the recent discussion on the composition of nephelite (*see* 19.383) may be cited. Analyses of this mineral invariably show an excess of silica over that required by the orthosilicate formula $NaAlSiO_4$, and sodium is always partly replaced by an equivalent amount of potassium in the varying ratio (Na:K) of 5·5:1 to 3:1, whilst a small amount of calcium is also present. Here the excess of silica (the ratio $SiO_2$:$Al_2O_3$ ranging from 2·1:1 to 2·2:1) has been assumed to be present in "solid solution" in an isomorphous mixture of $NaAlSiO_4$ and $KAlSiO_4$. The higher ratio of 2·2:1 is regarded as the "saturation ratio" of the silica, for when it is exceeded visible albite is found with the nephelite. Another view expresses the composition of nephelite as an isomorphous mixture in varying proportions of the following molecules, in one of which $SiO_4$ is replaced by $Si_2O_8$:—

| | |
|---|---|
| $NaAlSiO_4$ | (known as an artificial compound; soda-nephelite below 1,248° C., and as the triclinic felspar carnegieite above this inversion-temperature). |
| $KAlSiO_4$ | (the mineral kaliophilite). |
| $NaAlSi_2O_8$ | (hypothetical isomer of albite). |
| $Ca\frac{1}{2}AlSiO_4$ | (hypothetical isomer of anorthite). |

Or, again, the following series of "normal" nephelites, each representing a double compound of alumotrisilicic acid ($H_2Al_2Si_3O_{10}$) and alumodisilicic acid ($H_2Al_2Si_2O_8$), has been suggested:—

$$K_2Na_8Al_{16}Si_{11}O_{42} = K_2Al_2Si_3O_{10} + 4\ Na_2Al_2Si_2O_8.$$
$$K_2Na_9Al_{11}Si_{12}O_{48} = K_2Al_2Si_3O_{10} + 4\tfrac{1}{2}Na_2Al_2Si_2O_8.$$
$$K_2Na_{10}Al_{12}Si_{13}O_{50} = K_2Al_2Si_3O_{10} + 5\ Na_2Al_2Si_2O_8.$$
$$K_2Na_{11}Al_{13}Si_{14}O_{54} = K_2Al_2Si_3O_{10} + 5\tfrac{1}{2}Na_2Al_2Si_2O_8.$$

Whilst for a slightly more basic type is given the (highly improbable) formula:—

$$K_4Na_{18}Al_{22}Si_{19}O_{80} = 2K_2Al_2Si_2\tfrac{1}{2}O_8 + 9Na_2Al_2Si_2O_8.$$

Another, less complex, example is afforded by the mineral pyrrhotite (*see* 22.696). In its meteoric equivalent, known as troilite, the composition is quite simple, namely FeS, but in the terrestrial mineral there is always an excess of sulphur, as represented by the formulae $Fe_7S_8$, $Fe_{11}S_{12}$, etc., or in general $Fe_nS_{n+1}$. When pyrites ($FeS_2$) is heated it dissociates at 565° C. into pyrrhotite and free sulphur, and the composition of the resulting pyrrhotite varies with the temperature and the pressure of the surrounding sulphur-vapour. It is therefore concluded that the excess sulphur is absorbed by the ferrous sulphide, or in other words present in "solid solution," the formula being written FeS(S)$_x$. The absence of any excess of sulphur in the troilite of meteorites is accounted for by the coexistence of free iron.

*Radioactivity.*—The strong radioactivity of uranium minerals affords a ready means of recognizing these valuable ores in the search for them by prospectors. The mineral may be wrapped up with a photographic plate, which is afterwards developed; but a simpler and quicker test is that with a quite simple (home-made) gold-leaf electroscope. A piece of the mineral to be tested is placed on the cap of the electroscope, which is then charged with electricity, readily developed by rubbing glass or vulcanite (say the mouth-piece of a tobacco-pipe): if the mineral contains uranium (and consequently radium), the gold leaves will soon come together. It is always well to make a comparative test, timing the rate of collapse, with a piece of ordinary stone.

Determinations of the ratio of the amount of uranium to the amounts of the various products of its decay (radium, helium, lead, etc.) present in various radioactive minerals give (knowing the rate of the decay) some idea of the period of time during which these products have been accumulating. In this way estimates have been made of the age in years of these minerals and even of the age of the earth; but, of course, many unknown factors must have been omitted from such calculations. Lead of radioactive origin, or isotopic lead—the final product of the decay of uranium—is found to vary slightly in its atomic weight according to the uranium mineral from which it is extracted.

To radioactivity is ascribed the well-known "pleochroic haloes"—tiny spots or borders of deeper colour surrounding microscopic inclusions—long ago observed in certain rock-forming minerals (cordierite, andalusite, mica, etc.) when micro-sections of rocks are examined in polarized light. The long and continued emission of X-rays from zircon or other mineral grains has caused a change in colour of the surrounding mineral for distances varying from 0·002 to 0·04 mm. A study of these has again given some information as to the age of the minerals. In this connexion it may be mentioned that much experimental work on the coloration of minerals has been done within recent years by exposing the minerals to the action of radiations of various kinds, including ultra-violet rays, cathode rays, Röntgen rays and the rays emitted by radium salts. For example, some diamonds acquire a green colour, and fluorspar becomes blue when placed in contact with radium bromide.

*New Minerals.*—In descriptive mineralogy a considerable number of new minerals have been named, but unfortunately in many cases not completely determined and described. A few of the more prominent and well-established of these are:—

*Alamosite*, lead metasilicate, $PbSiO_3$, found at Alamos, Sonora, Mexico, as radially fibrous masses with snow-white colour and adamantine lustre. Crystals are monoclinic, and the mineral is analogous to wollastonite ($CaSiO_3$).

*Amosite*, a variety of monoclinic amphibole-asbestos rich in iron (FeO 32–44%) and consisting essentially of ferrous silicate with but little magnesia. It is of the "cross-fibre" type and resembles crocidolite in its mode of occurrence, thus differing from the ordinary type of amphibole-asbestos. It is found over a wide area in north-eastern Transvaal and is named from the Amosa asbestos mine, this word being formed of the initial letters of the company "Asbestos Mines of South Africa."

*Betafite*, a hydrated titano-columbate of uranium containing $UO_2$ 26–28%. It occurs in pegmatites near Betafo in Madagascar as sharply developed octahedral crystals with the edges truncated by faces of the rhombic-dodecahedron. Curiously flattened crystals are also found.

*Carnotite*, hydrated vanadate of uranium and potassium, $K_2O{\cdot}V_2O_4{\cdot}2U_2O_3{\cdot}3H_2O$, occurring as a canary-yellow crystalline powder impregnating sandstones over a wide area in western Colorado and the adjoining portions of Utah and New Mexico. In Colorado it has been collected on a large scale for the extraction of vanadium, uranium and radium. It has also been found in South Australia and in Pennsylvania; and an allied mineral (tyuyamunite, containing calcium in place of potassium) is known from Tyuya-Muyun in Russian Turkestan.

*Inyoite*, hydrated calcium borate, $2CaO{\cdot}3B_2O_3{\cdot}13H_2O$, found as large, colourless, monoclinic crystals in the borate deposits of Inyo county, Cal., and in the gypsum mines at Hillsborough in New Brunswick.

*Lorandite*, sulpharsenite of thallium, $TlAsS_2$, forming transparent, monoclinic crystals with a carmine-red colour and adamantine lustre. It is found with realgar at Allchar in Macedonia, and is one of the few minerals that contain the rare element thallium as an essential constituent (Tl 59·5%).

*Margarosanite*, metasilicate of lead and calcium, $PbCa_2(SiO_3)_3$, occurring as colourless or snow-white, platy masses and anorthic crystals with pearly lustre. It has been found at Franklin in New Jersey and at Långban in Sweden.

*Otavite*, basic carbonate of cadmium (Cd 61·5%), occurring as small, pearly white, curved rhombohedra on copper and lead ores at Otavi in South-West Africa. The only cadmium mineral previously known is the sulphide, greenockite.

*Patronite*, vanadium sulphide, $VS_4$, forming dark, greenish-black, compact masses. It occurs abundantly at Minasragra, Cerro de Pasco, Peru, where it is a valuable ore of vanadium. It weathers very readily with the production of various highly coloured vanadium compounds; even on material kept in collections there is a slow growth of blue and green efflorescences.

*Spencerite*, hydrated basic zinc phosphate, $Zn_3(PO_4)_2{\cdot}Zn(OH)_2{\cdot}3H_2O$, forming pearly white, scaly cleavage masses and small monoclinic crystals. It has been found in some abundance forming large stalactites in a cavern near Salmo, British Columbia.

*Stichtite*, hydrated basic carbonate of magnesium and chromium, $MgCO_3{\cdot}5Mg(OH)_2{\cdot}2Cr(OH)_3{\cdot}4H_2O$, occurring as foliated masses with pearly lustre and bright lilac colour. This colour forms a striking contrast to the bright green serpentine in which the mineral is embedded. It has been found in western Tasmania, in the Transvaal, and near Black Lake in Quebec.

*Tarbuttite*, basic zinc phosphate, $Zn_3(PO_4)_2{\cdot}Zn(OH)_2$, forming colourless, or faintly coloured green or red, anorthic crystals, with a perfect cleavage in one direction. It has been found in considerable quantity at the Rhodesia Broken Hill mine in northern Rhodesia.

*Thortveitite*, silicate of scandium, yttrium, etc. $(Sc,Y)_2O_3{\cdot}2SiO_2$, occurring as large orthorhombic crystals of prismatic habit in pegmatite in southern Norway and Madagascar. This is the only mineral known to contain the rare element scandium in large amount.

*Tungstenite*, tungsten sulphide, $WS_2$, forming minute scales resembling molybdenite and graphite in appearance. It is found intimately intermixed with other ores in the Little Cottonwood district, Utah.

REFERENCES.—Details of descriptive mineralogy are collected in Appendices 1–3 of Dana's *System of Mineralogy* (New York 1899–1915); and numerical data respecting the constants of minerals are tabulated in the international *Tables annuelles de constantes et données numériques* (4 vols., Paris 1912, etc.). A new work of a comprehensive character is C. Doelter, *Handbuch der Mineralchemie* (3 vols., Dresden and Leipzig 1912, etc.). A number of elementary text-books have been published, *e.g.* F. H. Hatch, *Mineralogy* (London 1912); G. A. J. Cole, *Outlines of Mineralogy for Geological Students* (London 1912); A. F. Rogers, *Introduction to the Study of Minerals* (New York 1912); A. H. Goldschmidt (Heidelberg since 1914). (L. J. S.)

**MINESWEEPING AND MINELAYING.**—Among the naval services rendered to Great Britain and the Allies during the World War, none were more conspicuously important than the work of British minesweepers and minelayers; and minelaying was a large item in the naval war record of Germany.

*Minesweeping.*—As early as 1907, Adml. Lord Charles Beresford, when commander-in-chief of the British Home Fleet, had recommended the use of Grimsby trawlers for the service of minesweeping. A trawler reserve, R.N.R. (T.), had been constituted under an inspecting captain of minesweeping vessels, and the system worked so well that by Aug. 8 1914, 96 hired trawlers had put to sea. The needs of minesweeping had, however, only partly been foreseen. When the war broke out the only minesweepers with the fleet were six torpedo gunboats fitted with the "A" sweep, a single wire kept at a required depth by waterkites and towed between two sweepers 500 yd. apart. It soon became evident that minelaying played an important part in German strategy, and after the "Amphion" had been sunk on the field laid off Aldeburgh by the "Königin Louise" on Aug. 5, a hundred additional trawlers were ordered and Lowestoft became the principal minesweeping base on the east coast. On Sept. 1 Rear-Adml. E. Charlton was appointed Rear-Admiral Minesweeping on the East Coast, in charge of minesweeping operations and technical arrangements, leaving the inspecting captain to attend to the business of supply.

Minesweeping at this time was largely in the experimental stage and some time elapsed before it was able to cope with the magnitude of its task. One of the first steps taken to ensure the safety of shipping was the institution of a war channel up the east coast, clearly marked by buoys 2 m. apart, from the Downs, past the Shipwash, Newarp and Cromer's Knoll to Flamborough Head. This was swept daily by local trawler flotillas and provided a safe channel up the east coast. Trawlers, how-

ever, were too slow for emergencies, and ordinary excursion paddle-steamers of light draught and good sweep were introduced with very successful results. A special design of sloop—the "Flower" class of 1,200 tons, 250 ft. long, 11 ft. draught and 16 knots—was laid down in large numbers, but these were not ready till April 1915.

The loss of the "Audacious" off Tory I. (Ireland, N.) on Oct. 27 still further emphasized the necessity of a large and efficient minesweeping service. The minefield laid by the German s.s. "Berlin" consisted of some 200 mines running approximately N.E.-S.W. north of Tory Island. It was not definitely located till Dec. 20, and, though 43 mines had been swept up and 70 drifted ashore by the end of April, was not cleared till July 1915. It must be remembered that the loss of a ship or the discovery of a mine merely served to indicate the proximity of a minefield. Before its extent could be defined and the clearance completed a number of exploratory sweeps were required which were often delayed by bad weather.

The German mines laid during 1914 were laid by surface craft in the following areas:—

| *Date* | *By* | *Area* | *Mines* |
|---|---|---|---|
| Aug. 5 | "Königin Luise" | Southwold | 180 |
| Aug. 26 | "Nautilus" | Humber | 200 |
| | "Albatross" | Tyne | 194 |
| Oct. 26 | "Berlin" | Tory I. (Ireland) | 200 |
| Nov. 3 | "Kolberg" | Smith's Knoll | 130 |
| Dec. 16 | "Kolberg" | Scarborough | 100 |

They accounted for 42 merchant vessels or approximately one vessel for 24 mines. The measures taken to meet the danger consisted in the establishment of a war channel and the preliminary steps for a great expansion of the minesweeping service.

Minelaying played an important part in the German raids on the east coast, and the raid on Dec. 16 1914 was intended to cover a minelaying operation by the "Kolberg," in which she laid 100 mines off Scarborough. Two of these mines were found by gunboats on Dec. 19, and half an hour later a Grimsby trawler minesweeping unit brought 18 to the surface simultaneously. Two of its trawlers struck mines and the field was not finally cleared till April 1915, 69 mines being accounted for out of 100 laid, with heavy losses to shipping, including 7 British and 7 neutral steamers, 2 trawlers, 4 minesweepers and an armed yacht.

By April 1915 the minesweeping forces had increased considerably and were distributed as follows:—Grand Fleet, 6 gunboats, 1 sloop and 9 trawlers; Scotland, east, 47 trawlers; Humber, 6 paddlers, 30 trawlers; Lowestoft (war channel), 47 trawlers; Harwich and Nore, 33; Dover, 12; South Coast, 24; West Coast, 4; Clyde, 6 paddlers (fitting out). The principal minefields laid by German surface craft in 1915 were:—

| | | |
|---|---|---|
| Spring 1915 | Eastern Dogger Bank | 480 |
| April 4 | Humber approach (Swarte Bank and Indefatigable minefields) | 360 |
| Aug. 7–8 | Moray Firth by "Meteor" | 380 |
| Jan. 1 1916 | Whiten Bank (west of Orkneys) by "Moewe" | 252 |

The Eastern Dogger Bank minefield was large but not a single British vessel of any size was lost in it. Sixty-nine mines were swept up there and the swell of the winter sea probably completed the task of clearance.

The fields off the Humber were responsible for the loss of 4 British, and 5 neutral steamers and 3 minesweepers, but the field was defined by May 1915; 127 mines were swept up that month and by the middle of July it was clear. The fields laid by the "Meteor" in Aug. 1915 and by the "Moewe" on Jan. 1 1916 were aimed directly at the Grand Fleet. The "Meteor" made the Scottish coast at dusk on Aug. 7 and, starting from a position about 22 m. N. of Kinnaird Head, laid 380 mines in the approach to the Moray Firth during the night. The first notification of them came from a Cromarty trawler minesweeper making a routine sweep on the morning of Aug. 8. The destroyer "Lynx" was lost the same day and the sloop "Lilac" had her bows blown off. After clearing a 10-m. channel along each shore and removing 222 mines, the rest of the field was left unswept as a protection against similar attacks. In the final mine clearance in 1918 only four mines were found in it.

The German minefields on the east coast gave rise to the erroneous idea that they were associated with a prospective landing operation. An equally erroneous idea that mines were laid by neutral trawlers obtained so firm a hold in the Grand Fleet that it led the commander-in-chief to ask for the exclusion of all neutral trawlers from British ports.

In the Mediterranean minesweeping played an important part in the attempt to force the Dardanelles. The problem was the same as that which confronted the Germans at Ösel in the Baltic in 1917. The task was one of peculiar difficulty, for it meant sweeping under the fire of batteries, and the strong current reduced the speed of trawlers with sweeps out to less than 3 knots. It was a task which required high-speed sweepers and a highly trained personnel, and even with their agency its feasibility may be doubted. The technical difficulties of the task were greatly underestimated. It was regarded as a simple piece of work which any vessel fitted with a sweep could perform, and it was attempted with a motley collection of slow trawlers, assisted by a parcel of destroyers fitted with sweeps for the first time. The sweep principally used at this time and throughout the war was the "A" sweep, consisting of a single 2½-in. wire towed between two ships steaming 500 yd. apart, with its depth regulated by a water-kite 12 ft. long and weighing a ton. The end of the wire had to be passed from one vessel to the other and to do this rapidly under fire required an exceptional combination of training, skill and courage. In the case of fast sweepers, the momentum of the wire was sufficient to cut the mooring of the mine, but slow sweepers in the early years of the war had to take their sweeps into shallow water where the mines could be seen and sunk. This made sweeping slow work, and it also meant that the "A" sweep was really only effective by day; so that sweeping a minefield under heavy fire was almost impracticable.

The year 1915 saw an important development in the use of submarines for minelaying by the Germans. The Flanders Flotilla were the first workers in this field and their mines were first discovered off the S. Foreland on June 2 1915. These were laid by small boats termed UC boats, equipped with 12 cylindrical mines with charges of 350 lb. of T.N.T., carried in vertical shoots. The mine dropped with its sinker to the bottom and was released from the sinker by a "dashpot" arrangement about half an hour after reaching the bottom, giving the submarine time to get clear. The mooring-wire coiled into the sinker was drawn off by the mine as it rose, and when the proper depth was reached it was gripped by a strong spring clamp released by a hydrostatic valve. Submarine minelaying threw a heavy strain on the minesweeping forces at Harwich, Dover and the Nore, which were the areas principally affected at first, and the continuous location of small groups of mines gave rise to an incessant stream of orders for the diversion or stoppage of traffic which greatly hampered coastal navigation.

The Germans report having laid 648 mines between Grimsby and Dover by submarines in 1915, of which 150 were laid in the Dover area (not including the Belgian and French coasts), 180 off the Nore, 306 in the Lowestoft area and 12 off Grimsby. The number of mines swept up in this area was approximately 500, and the losses in the last six months of the year showed a serious increase, comprising 3 destroyers, 5 supply ships, one hospital ship, 2 Trinity House vessels, 34 British steamers, 24 neutrals, 10 fishing boats, 15 minesweepers (3 paddlers, 9 trawlers)—a total of 94 vessels. In June 1915 the Germans had extended their minelaying to Archangel, and a unit of 6 trawlers had to be despatched there; the unit destroyed over 150 mines by October, with the loss of H.M.S. "Arlanza," one trawler, 6 British steamers, one Russian and 2 neutrals.

The "Actaeon" sweep, called after the parent ship of the Sheerness torpedo school, came into use at this time. It was a single-ship sweep, consisting of a light wire, a small kite, a depth float and an explosive grapnel, and was towed from each quarter of a minesweeper. On meeting a mine, the explosive grapnel parted its mooring; the sweep proved particularly useful in locating new fields, and had the advantage over the "A" sweep that it could be used by night.

The outlook at the end of 1915 was far from bright, and the minesweeping service was barely able to meet the strain in spite of the better design and greater number of its ships.

By the beginning of 1916 the hired paddle-sweeper force had grown to five units, numbering 35 vessels in all, and 14 sloops were in commission with the Grand Fleet. Twenty-four Admiralty paddlers of 810 tons and 6¾ ft. draught were being built and were distributed during the year between the Forth and Dover straits. A new type of twin-screw sweeper of 750 tons with a draught of only 7 ft., called the "Hunt" class, was completing and the whole batch of 12 was allocated to the Grand Fleet. The Burney paravane was also past its trial stage and by the end of the year was supplied to all ships of over 12 ft. draught. This instrument was the product of Lt. Denis Burney's genius. Shaped like a torpedo and about 12 ft. long, it was towed from a special shoe on each side of the bows, being held at its proper depth by a hydrostatic arrangement and at its proper distance by rudders. The mooring-wire of any mine it met was swept clear of the ship into jaws of serrated steel and quickly cut. The mine came to the surface and could be sunk. The "otter" was a modified form of paravane for use in merchant ships where its fitting became compulsory in 1917. The paravane justified its adoption: 180 warships and 2,740 merchant ships were fitted with it; in the former it cut 55 mine wires during the war, and in the latter at least 40 or 50. Another simpler but useful invention, in the form of a special sort of serrated wire for sweeping, also dates from 1916; it could cut through a mine's mooring-rope when towing it no faster than a trawler (4 to 5 knots).

Surface minelayers were still active, and the raider "Moewe" on her way out to the ocean laid a large minefield of some 250 mines on New Year's day, 1916, on the west side of the Orkneys. Commencing about 10 m. from the Orkneys it ran in zig-zags at 3 to 7 m. from the mainland. The loss of the pre-dreadnought battleship "King Edward VII." on the morning of Jan. 5 was the first sign of it, and two neutral steamers were sunk in the same field. Gales interfered seriously with its clearance but by May some 71 mines had been destroyed. All other German mines laid in 1916 were laid by the submarine flotillas, which were now reinforced by a number of UC boats carrying 18 mines and by several larger boats (U71–80) carrying 34 to 36. Some were attached to the Flanders Flotilla and worked from Bruges and Zeebrugge; others, including the larger minelayers, were attached to the High Sea Fleet and worked from the Elbe. Each of the two flotillas was allotted a separate area of the British coast for minelaying. The High Sea Fleet boats worked N. of Flamborough Head. The Flanders Flotilla area comprised the coastline from Flamborough Head to Dover, the English Channel, the Irish Sea and Irish S. coast to Waterford.

A field laid on the west coast of the Orkneys was to have an unforeseen result. It was laid on May 29 by the U75, one of the large minelayers, as part of the Jutland operations, and at 8 P.M. on June 6 the "Hampshire" on her way to Archangel struck a mine in it off Marwick Head, foundering almost immediately and bringing Lord Kitchener's career to a dramatic close. A trawler unit, searching the spot as soon as the weather moderated, found 15 mines laid at 7 metres in a spot where the strong current and tidal dip would have enabled the "Hampshire" to pass over them in a normal sea. From May to Oct. 1916 German minelaying in the English Channel ceased as a result of an imperial order, dictated by the American note of April 18, to confine submarine warfare strictly to the conditions of prize law. Scheer went further than the imperial command, and ordered his flotillas on April 24 to cease all operations against merchant ships, while the Flanders boats, following suit, limited themselves to minelaying off Lowestoft, Harwich and the Nore.

In Oct. 1916 submarine operations against merchant shipping were resumed, and minelaying broke out with renewed activity. Mines were laid off the Clyde (Oct. 3) and in November off the Isle of Man. The close of 1916 saw a determined attack by the Flanders submarines against the ports in the Channel and mines were laid off Portsmouth, Dartmouth, Plymouth and Falmouth. The French coast opposite Dover was also heavily mined. In the Dover area 212 mines were laid during the year (not including 100 off Dunkirk, 100 off Calais and 60 off Boulogne), with a loss of two destroyers, five minesweeping trawlers and 20 steamers.

The unrestricted submarine warfare in 1917 was accompanied by an increase in submarine minelaying, and in the month of April 515 mines were swept up, considerably more than in any previous quarter. The reorganization of the naval staff led to considerable changes in the minesweeping service. The director of torpedoes and mining now took charge of the development, supply and distribution of gear, while the control of operations and the distribution of all vessels was delegated to a captain of minesweeping (Capt. Lionel Preston), who in Oct. 1917 became director of the minesweeping division under the assistant chief of the naval staff. Losses in minesweeping vessels were heavy in the early part of the year, amounting to as many as one *per diem* in April 1917, but the use of aircraft patrols and of shallow-draught motor-launches proved useful in locating mines and diminished the loss of heavy-draught sweepers. The extended range of enemy minelaying and the heavy losses amongst minesweepers led to an increased demand for them. Thirty small paddle-steamers, 10 small tugs and 18 drifters were requisitioned, and orders were issued for the construction of 100 more "Hunt" class (800 tons, 7½ ft. draught, 18 knots) and 300 drifters.

The war channel now ran up the east coast as far as the Tees in the shoalest possible water, and shipping was released from various night anchorages in the Downs, Black Deep and Great Yarmouth as soon as it had been swept at dawn. Improvements in organization during the year led to a reduction of 20% in merchant-ship losses, though the mines swept up were double those in 1916.

The operations of the High Sea Fleet Flotilla were extended in the spring of 1917 to the Minch and the routes of the west coast of Scotland used by destroyers and fleet auxiliaries, much of the work being done by the U80, one of the large submarine minelayers. In 1916 195 distinct mine groups had been laid, chiefly on the east coast; in 1917 the number rose to 536 and the sphere of operations extended right round the British Isles. This involved a further expansion of the minesweeping service, and the fast sweepers (sloops, gunboats, paddlers) increased from 93 to 122, the slow (trawlers, drifters) from 430 to 509. The deep water off the Yorkshire coast had been a favourite cruising ground for submarines, but large protective minefields were now laid there as an off-shore protection with good results.

The Harwich area was exceptionally busy in 1917, and its work in that year must rank as one of the principal minesweeping achievements of the war. Mines were regularly laid by German submarines in the latter part of the year to catch the Holland trade, and a new minefield off the Maas Light, laid in April 1917 and regularly renewed, became a source of constant trouble. Out of 680 mines laid 635 were destroyed, with the loss of four merchant ships and eight minesweepers. The enemy had to pay a heavy toll for his work, and lost 12 minelaying submarines in the southern portion of the North Sea during 1917. The port of Liverpool, as the principal arrival base for Atlantic transports, was a constant source of anxiety, and at the beginning of 1917 had only two minesweeping trawlers attached to it. Mines were reported there on March 24 1917, and on April 9 the "New York," with Adml. Sims on board, struck a mine, but the port was fortunately left alone till December, by which time the protective arrangements had greatly improved. Of 45 mines laid in the Mersey area 33 were accounted for, with the loss of five merchant ships and one pilot steamer in which 28 pilots lost their lives. In the W., Lough Swilly and the approaches to the Clyde were all mined during 1917, some 88 mines being laid in this area and off Belfast, of which 72 were destroyed, with the loss of four steamers, one destroyer and five trawler minesweepers. The south coast of Ireland also became a regular region of visitation, and the small tidal range and heavy swell made minesweeping particularly dangerous there. The 10th Sloop Flotilla was sent from Immingham to Queenstown in Feb. 1917 to cope with the new danger, and two of its sloops were mined in the following

month. It was off this coast the UC44 was working in summer, to be blown up on Aug. 4 by one of her own old mines off Waterford. Out of 380 mines laid by the High Sea Fleet minelayers and 36 by the Flanders Flotilla in this area, 332 were accounted for with the loss of nine steamers and nine minesweepers. Some 26 mines were also laid off the west coast of Ireland, but did no damage, except in one case where the villagers mistook one which had drifted ashore for a new sort of cask of liquor and tried to open it, with the loss of nine lives. Off the west coast of Scotland, out of 130 mines cleverly laid by the U80 off Mull, Stornoway, Coll, Skye and Harris, 76 were accounted for.

The year 1917 closed with a total of 3,989 enemy moored mines swept up in home waters, at a cost of 170 Allied and neutral merchant ships sunk and 28 damaged. The whole outlook was more hopeful, for while enemy minelaying as compared with 1916 had more than doubled, the number of ships sunk had increased only from 161 to 170.

Abroad the voyage of the German raider "Wolf" (Capt. Karl Nerger) had given minesweepers work in many an unexpected spot. She left Germany on Nov. 30 1916, slipped through the blockade line and got safely out to sea. She was a ship which registered 6,000 tons and carried 458 mines besides an armament of four 6-in. guns. Her voyage lasted 15 months. Rounding Cape of Good Hope, she cruised in the Indian Ocean, then proceeded south of Australia to New Zealand and Fiji, and, returning by New Guinea, the Dutch East Indies and the Cape, reached Germany safely in March 1918. Her mines were found all over the globe. Her first group of 25 was laid off Dassen I. (Capetown) and her second of 29 on Jan. 18 off Cape Agulhas (S. Africa). The former were swept up by four whaling steamers commissioned for the purpose. In the Agulhas field two vessels were lost and only seven mines swept up in 1917. On Feb. 15 1917 39 mines were laid off Colombo and 19 off Cape Comorin (Ceylon). One of her prizes, the "Turritella" (renamed "Iltis"), dropped some 25 off Aden, and a large group of 68 mines off Bombay was laid by one of the two ships. The Colombo group was swept up by six trawlers, with the loss of two large ships. The Aden group was dealt with by small harbour tugs manned by Somalis within two months of its location and with the loss of one ship. The large group off Bombay was attacked by local vessels manned by British officers and Lascars, and 51 of its mines were swept up by June with the loss of five steamers.

The "Wolf's" next mining exploit was in Australian seas, where she laid 14 mines off Gabo I., the S.E. point of Australia, between Melbourne and Sydney, with the loss of one steamer; this was followed by a cruise to New Zealand, where 15 mines were laid in Cook Strait, between North and South Is., and 17 off Three Kings I. in the extreme north. These were all dealt with by Australian and New Zealand naval forces. Her last effort consisted of 110 mines laid N.W. of the Andaman Is. (Indian Ocean) on Sept. 4 1917, which were not located in that year. Her mines were responsible for the loss of some 15 ships, and it was not till Jan. 15 1918 that definite news of her movements was received at the Admiralty.

But by 1918 the effect of improved British methods was telling heavily on the enemy. The toll of German losses and the difficulty of replacing trained personnel were seriously affecting her minelaying, and the total number of Allied and neutral merchant vessels lost by German mining fell to 27. Closer coöperation between the intelligence and minesweeping divisions, the rapid distribution of intelligence, the firmer control of shipping and the use of the "otter"—all contributed to this very marked decrease.

The Germans now began to concentrate their minelaying efforts in three special directions—the maintenance of a minefield off the Dutch coast directed against the Dutch convoys, the laying of a large semicircular barrage about 45 m. from the Forth aimed at the Grand Fleet, and attacks on the route of the Scandinavian convoys. The first took the form of a field laid off Ymuiden and the Maas containing some 400 mines, which was extended by the labours of two U-boat minelayers working continuously in this area. It was responsible for the loss of five destroyers and remained a source of grave danger, for minesweepers working there were exposed to sudden attacks from the Flanders coast. The barrage off the Forth met with no success. The mines were rapidly located (in two cases by paravanes) and swept up almost as soon as they were laid. The attacks on the Scandinavian convoy routes were equally unsuccessful. Some 90 mines were swept up with the loss of only one steamer.

In the Harwich area 265 mines were laid, of which 213 were accounted for, with the loss of five steamers and four minesweepers. The discovery of a mine off Walney I. (Lancashire) on March 8 led to special vigilance in that area, and when mines were laid in the Mersey the next night, a unit of paddlers, held in readiness for the emergency, was at work at once clearing the fairway and opened the port to traffic within 48 hours.

The introduction of a French pattern of scissors to cut through the mooring-wire of a mine was one of the developments of the later years of the war, though the difficulty of minesweeping did not lie in cutting the mine's mooring-wire when found but in finding the mine in a trackless expanse of water under all sorts of conditions of tide and weather.

A very considerable amount of minesweeping work in 1918 arose out of British minelaying. The mines in a portion of the northern barrage were laid too shallow and had to be swept up in the approaches to the Orkneys. The same fault was found in Dover barrage, where some 280 mines had to be swept up and a great increase in drifting mines was experienced. The Channel still continued to be visited occasionally, and in the Portsmouth area 44 mines were accounted for with the loss of two merchant ships and two minesweepers.

In the Mediterranean, the enemy had devised a mooring system for tideless waters which permitted of mines being laid in 100 fathoms, but the clear blue water lent itself to aircraft reconnaissance which, in concert with light-draught motor-vessels, made location easy. Thirty mines were destroyed off Malta during the year 1918 with the loss of one steamer. The minesweepers were largely manned by Maltese reservemen who displayed a gallant spirit and seamanlike competency in their work.

Long before the Armistice, British minesweeping had gained the mastery over German minelaying, and as soon as Ostend and Zeebrugge fell into British hands, the protective minefields round them were swept up. When the hour of the Armistice struck, a minesweeping force was waiting at the gate of the Dardanelles, and within 24 hours 600 British and enemy mines had been removed from the entrance and a passage cleared for the fleet to Constantinople.

A few words may be said as to the method of distributing information of mines. This was sent out in what were called, from their index letter, "Q" messages, which were priority messages going to all shore stations by land wire and to all forces at sea by Cleethorpes wireless station at regular intervals. Immediately a mine was discovered or swept up, the spot was buoyed and local traffic at once diverted or, if the mine was in the war channel, held up. As soon as tidal conditions permitted, the area was swept. The text of a "Q" message was sent by the senior officer to the Admiralty, and, after being checked by the Minesweeping Division, was at once sent out to all ships and stations, the average time from the discovery of a mine to the issue of information to ships at sea being about 1½ hours.

The growth of the minesweeping service and the greatness of its task, performed largely by British fishermen, may be gathered from the following figures. At the Armistice the minesweeping forces in British home waters comprised 110 fast sweepers organized in 20 minesweeping flotillas, 52 hired paddlers, 412 trawlers, 142 drifters and 10 "Dance" minesweepers—a total of 726 vessels. The number of mines destroyed at home and abroad by British vessels during the war amounted to 23,873 (moored, 11,487; drifting, 12,386). The ships sunk and damaged by mines numbered 595. The number of minesweepers sunk or damaged was 214, in the following areas: Fleetsweepers, 5; Lerwick, 1; Kirkwall, 3; Cromarty, 3; Peterhead, 2; Granton, 9; Tyne, 6; Grimsby, 15; Lowestoft, 48; Harwich, 24; Nore, 15; Dover, 33; Portsmouth, 13; Portland, 1; Plymouth, 3; Falmouth, 2; Bristol Channel, 6; Queenstown, 7; Belfast, 6; Clyde, 2; Stornoway, 1; abroad, 9.

*Minelaying.*—Minelaying played a very important part in the later years of the World War, but to form a true estimate of its value a careful distinction must be drawn between three factors essential to its success—its strategical use and function, the

technical design of the mine, and the operation of minelaying. The offensive power of the mine and its place in naval strategy had not been appreciated at the outbreak of war. Its use for the defence of harbours had been abandoned by Lord Fisher several years before; and though a squadron of seven old cruisers had been converted into minelayers ("Andromache," "Apollo," "Intrepid," "Iphigenia," "Latona," "Naiad" and "Thetis," 3,400 tons, 18-ft. draught, 14 knots), more than two years were to pass before discovering a reliable mine. This was properly the task of the torpedo school-ship "Vernon," but hampered by lack of funds its work was not attended with very happy results. The details of the Russian mine were well known to the British authorities. It was simple and effective and the pattern was adopted by the Germans with conspicuous success, but it cost some £200 and the British had to be content with a cheaper one. This was the naval spherical mine, and at the outbreak of the war there were 4,000 available.

The original plans had provided for laying mines in the southern part of the North Sea, and the notices to mariners and neutrals were ready to print when it was found that the pistol was too sensitive and the mooring-wire too weak. The older admirals were also inclined to deprecate them, on the grounds that the British should keep the sea as open as possible for the use of their own ships. The sinking of the "Cressy," "Hogue" and "Aboukir," which left the Belgian coast open to attack, startled the navy out of this opinion, and it was decided by Great Britain to lay mines in the North Sea. This was notified to neutrals, and the first line of 1,264 mines was laid on Oct. 2 1914, 10 m. N. of Ostend. In Nov. mines were reintroduced for defence of harbours, and a special corps of Royal Marine submarine miners was started to manipulate them. By the end of 1914 some 2,000 mines had been laid in the southern part of the North Sea, which had a good effect in forcing neutral shipping to pass through the Downs, and for a time deterred enemy submarines from approaching the Channel. During 1915 a number of fields were laid in German waters and the minelaying squadron was greatly strengthened. It now consisted of the "Princess Margaret" (Canadian Pacific railway, 5,440 tons, 21 knots, 500 mines), the "Paris" (cross-Channel, 2,030 tons, 25 knots, 80 mines), "Angora" (Calcutta to Rangoon, 300 mines), "Biarritz" (S. E. & Chatham railway, 2,700 tons, 21 knots, 305 mines); but the mine still lagged behind the minelayer, and in June the British Elia mine was found to be so defective that minelaying ceased for a time.

On May 27 1915 the loss of the "Princess Irene," which was blown up at Sheerness by an internal explosion, was a severe blow to the minelaying service. In the Narrows 15 more minefields were laid during the year, chiefly between the Goodwins and the Belgian coast.

By 1916, the importance of mining in North Sea strategy was beginning to be realized, but an efficient mine was still lacking. There could be no question that the German mine was much more efficient. It was a spherical mine, fitted with lead horns containing a sealed glass tube which held the liquid for exciting an electric cell. When the mine was struck, the lead horn bent, the glass tube broke, the liquid ran into the cell and the mine fired. It was held to the sinker by a catch, and went to the bottom with it when dropped, leaving the water free for the minelayer. After an interval of half an hour or so, glycerine escaping from a dashpot gave play to a plunger which released the catch, and the mine rose gradually to the surface, uncoiling a double mooring-wire from inside the sinker. On reaching its correct depth from the surface, a hydrostatic valve released a strong spring clamp, which clamped the mooring-wire and held the mine at its correct depth. The British mine was more complicated, and, instead of concentrating attention on the production of a good mine, efforts were wasted in an attempt to devise a combination of mines and nets which achieved little or nothing.

The ordinary minefield was usually laid so as to be about 10 to 15 ft. below the surface at low water, but the success of the submarine gave rise to the conception of deep minefields laid at about 60 to 150 ft. to intercept the submarines when submerged.

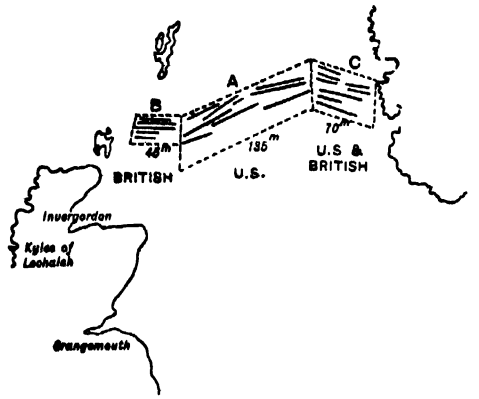
The ordinary surface minelayers now began to be supplemented by submarines and destroyers; the E24 was one of the earliest boats to be fitted for this purpose, and the destroyer "Abdiel" was equipped to carry 80 mines. They were both busy laying minefields in German waters in 1916. The E24 laid a field close to the Elbe on March 3, but never returned from her next trip on March 21; and a field was laid by the "Abdiel" off Horn's Reef on which the "Ostfriesland" struck on June 1 when returning after Jutland. One of the principal British minelaying efforts of 1916 was the Belgian coast barrage, consisting of a double line of deep mines laid about 12 m. off the Belgian coast for some 40 miles. It was begun from Dover on April 24 1916, and consisted of some 1,565 mines, which took some five weeks to lay. The minelayers engaged were the "Princess Margaret" (Capt. Lockhart Leith), "Orvieto" (Capt. H. Smyth), "Biarritz" (Capt. E. Morant), and "Paris" (Comm. John May), under Capt. F. S. Litchfield Speer, supported by Dover and Harwich destroyers and the monitors "Prince Eugene" and "General Wolfe." Three German destroyers sallied out from Zeebrugge on April 24, but were engaged by the "Medea" (Comm. V. F. Gibbs), "Melpomene" (Lt.-Comm. H. De Burgh) and "Murray" (Lt.-Comm. H. Taprell Dorling), and driven off, though the "Melpomene" was badly hit by shore batteries.

The lines of mines were supplemented by mine nets laid by the Dover drifters about a mile to rearward of the mines.

This was the first big undertaking against the submarine, and did not meet with conspicuous success, for with the exception of the UB3, destroyed by a drifter on April 24, no submarine seems to have been sunk by it.

The end of the year saw the institution of a mining school for research and development, and this segregation of the work from the torpedo school, already burdened with torpedoes, electrical engineering and wireless, probably contributed to its efficiency. The Belgian coast barrage was erroneously supposed to have been the cause of the reduced submarine activity in the Channel during the summer, and a similar barrage was now begun across the Straits from the Goodwins to Snouw Bank on the Belgian coast. The nets were 60 ft. deep, each fitted with two mines and hanging from buoys 500 yd. apart. A line of deep mines was laid on their south side, from 54 ft. below the surface to within 30 ft. of the bottom. This field was completed on Feb. 8 1917 by the "Princess Margaret," "Biarritz" and "Paris." Later, the mines dragged into the nets and sank the Trinity House tender "Alert" while tending them. It was considered necessary to sweep the field up and relay it, which took the best part of June-July 1917. The work of 1917 lay chiefly in Heligoland Bight. In Jan. 1917 Adml. Beatty urged the necessity of mining on the largest scale, and proposed a line 157 m. long encircling the Bight, to be watched by light cruisers and destroyers. This was the first task given to the Plans Section, but unfortunately there was a great shortage of mines for the work and the British Elia mine was considered unsuitable. As these fields were intended to be permanent, an official notification of the field was made on Jan. 25 1917.

The Dutch Government, for the convenience of their trade, moored a line of four light-vessels and seven light-buoys which ran for some 180 m. N. and S. to the west of the western limit of the British notified area (light-vessels in 56°N., 5°E.; 54° 47′ N., 4°8′E.; 53°29′N., 4°2′E.; 53°N., 4°5′E.). Their lights, blazing out at night and immune from attack, became so well known a seamark as to earn the name of "Piccadilly" from the submarines and destroyers plying to and fro. During the year 1917 15,686 mines were laid by the "Abdiel" and the minelaying submarines (E24, 41, 45, 51, 34) and led to the loss of a number of German destroyers and minesweepers. The fields in the southern portion of the North Sea were reinforced by 1,120 mines in June 1917, and during the summer a mine-net barrage was laid at the entrance to the Adriatic from Cape Otranto to Fano Is., 45 m. long.

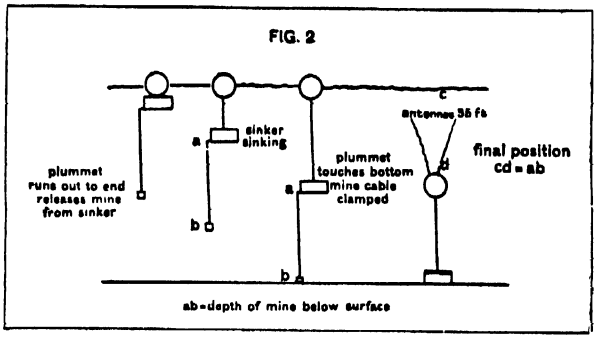


In 1917 the British Admiralty realized that minelaying on a large scale ranked as one of the principal operations of the war, though it was not till September that an efficient mine (pattern H2) began to be turned out in sufficient quantities.

In anticipation of the increased requirements some 12 modern light cruisers had been equipped for minelaying, and a batch of destroyers was fitted out to assist the "Abdiel" ("Tarpon," "Legion," "Telemachus," "Ferret," "Vanoc," "Ariel," "Vanquisher," "Vehement," "Venturous," "Sandfly," "Meteor"). These were to form the 20th Flotilla under Comm. Berwick Curtis, and to lay some 21,500 mines in the Bight in 1918. Meanwhile another big scheme had been propounded, involving nothing less than the closure of the northern exit of the North Sea to submarines, an area 230 m. in length with depths varying from 45 to 150 fathoms. The line first suggested was Aberdeen to Ekersund (Norway), but this was changed to Orkneys to Udsire, to bring it more closely within the purview and under the protection of the Grand Fleet.

FIG. 1

NORTHERN BARRAGE



1918

It was divided into three large areas:—B, next the Orkneys, 45 m. long; A, in the centre, 135 m. long; and C, on the Norwegian side, 70 m. long. These required 65,700, 36,300 and 18,000 mines respectively, a total of 120,000, and it was intended to lay nine rows: three at an upper level of 80 ft., three at a middle level of 160 ft., and three at a lower level of 240 feet. A was laid by the U.S. navy; B, by the British; C, by both. An immense organization for transporting, filling, loading and laying the mines grew up round the work. The American base was at Inverness, under Rear-Adml. Joseph Strauss, with Capt. Reg. Belknap as chief-of-staff, and their mines were landed in the Kyles of Lochalsh near Skye and sent across by the Caledonian canal and by rail. The British mining base was at Grangemouth in the upper reaches of the Forth, under Rear-Adml. Lewis Clinton Baker, with Capt. Lockhart Leith as chief-of-staff.

The first mine was laid on March 3 1918, and on May 26 the American squadron (Mine Squadron I.) arrived at Invergordon to take part in the work. It was under Capt. Reg. Belknap and consisted of the U.S.S. "San Francisco" (Flag-Capt. H.V. Butler), "Baltimore" (Capt. A. W. Marshall), "Roanoke" (Capt. C. D. Stearns), "Housatonic" (Capt. J. W. Greenslade), "Canandaigua" (Capt. W. H. Reynolds), "Canonicus" (Capt. T. L. Johnson), "Quinnebaug" (Comm. D. P. Mannix), "Saranac" (Capt. Sinclair Gannon), "Shawmut" (Capt. W. T. Cluverius) and "Aroostook" (Capt. J. H. Tomb), with a total capacity of 5,530 mines. Some 57,000 mines were laid during the next five months by the U.S. squadron, escorted on their expeditions by British and American warships. The mine was of American design (see fig. 2), carrying 300 lb. of T.N.T. and weighing with the sinker 1,400 lb. Antennae 70 ft. long (reduced to 35 ft.) rose from it, which fired the mine if touched by a ship. It was moored by a ½-in. wire cable, and attached to the sinker or anchor was a 90-lb. plummet on a reel of ½-in. steel wire, carefully measured to the length that the mine was to lie below the surface (160 ft., for instance, at the middle level). The mine was

FIG. 2

attached to the sinker, and, as it dropped from the steel rails astern, floated for a time. The plummet was released and ran out to the length of its cord, when it was brought up with a jerk. This released the mine from the sinker, which sank slowly with the mine cable running out. When the plummet touched bottom, the cord slackened, releasing a clamp which clamped the cable, and the sinker now pulled the mine down with it to the proper depth.

Difficulties were encountered as the work proceeded. A proportion of mines (about 5%) exploded prematurely, and a number of mines in the British area were laid at less than the prescribed depth of 65 ft., which led to the sinking of the British sloop "Gaillardia" on March 22 1918. It was decided to sweep up the mines in the British portion, and when relaid a large gap was left off the Orkney coast to ensure a safe passage for the fleet. The work of laying this field was one of the great achievements of the war, and the accuracy of position required was facilitated by the use of the "taut"-wire method introduced by Vice-Adml. Sir Henry Oliver, in which the distance run was measured by fine piano-wire reeling out from 140-m. spools. To prevent defective mines setting off others, the distance between lines was increased from 150 to 300 ft., and the rows increased to 10 at the upper level, 4 at the middle and 4 at the lower. The work of the American squadron marked a great step in minelaying, and it was no unusual feat for a single ship to lay a line of 860 mines covering 43 m. in 3½ hours.

It must not be supposed that the whole of the water available for a submarine was effectively covered by this field, but the danger of the passage was greatly increased. In July the minefield began to take its toll, and two German submarines were damaged in it, though they managed to get home. They now began to creep past in Norwegian waters, but the Norwegians closed them to both belligerents by minefields of their own. This barrage must be regarded as a colossal attempt to solve the submarine problem, and as it was barely completed by the Armistice a comprehensive judgment of it is hardly possible. It showed every sign of success, and in September and October at least four German submarines (including U92 Sept. 9, UB104 Sept. 19, U156 Sept. 25, U102 probably, UB127 probably, UB123 Oct. 19) were lost in it, with a proportionate effect on the *moral* of their officers and men who saw their last means of exit closing before their eyes. The United States laid 56,571 mines in it, and the British 13,546.

In the south the old cross-Channel mine-net barrage had been abandoned early in the year, and Rear-Adml. Sir Roger Keyes' efforts were concentrated on the Folkestone to Gris Nez barrage, where 9,570 mines were laid with conspicuous success. Nine submarines were lost in it (U109, UB38, UB58, UB33, UB55, UB31, UC38, UC64, UB103), and the High Sea Fleet flotillas abandoned the Dover route early in the year.

The mining of the Bight went steadily on, performed by the 20th Flotilla under Comm. Berwick Curtis and the minelaying submarines. On March 27 the "Abdiel," in company with the "Legion," "Telemachus," "Vanquisher," "Ariel," and "Ferret," were laying a field 70 m. N.W. of Heligoland when they came on three outpost vessels, which they sank, bringing back 72 prisoners. The E34, which left Harwich July 14 to lay a field off Vlieland, never returned. These operations led to the destruc-

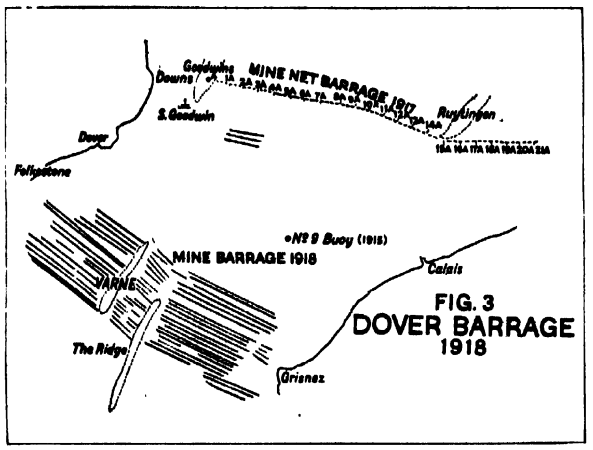


FIG. 3
DOVER BARRAGE
1918

tion of a number of minesweepers and torpedo craft, and though only one or two German submarines were lost on the mines their movements were undoubtedly seriously hampered.

In July the Germans suddenly began laying large protective minefields close to the Dutch line of lights, which resulted in the loss of the "Vehement" and "Ariel" on Aug. 1 and led to a great reduction in British mining in the Bight in the last three months of the war. The dangers of the Bight led to an increased use of the Cattegat by German submarines, and opened an excellent opportunity for deep mines in that area. A field was laid off the Skaw in February, and another in April off Lessö, which evidently caused considerable anxiety in Germany, but the work in this area was sporadic and did not form part of a coherent plan. Controlled minefields (that is, fields fired by instrumental means from a post in the vicinity on the passage of a submarine over them) were now being developed, and three submarines succumbed to them in 1918 (UC11, Harwich, June 26; UB109, Folkestone, Aug. 19; UB116, Scapa Flow, Oct. 28).

A large protective minefield of three deep and three shallow lines holding some 9,000 mines was laid in August and September off the coast of Yorkshire and Durham, where submarines were particularly troublesome.

Minelaying by the end of the war had developed into one of the most important operations, and, favoured by geographical conditions, played a very important part in later British strategy, being an indispensable feature of the war against the submarine. The enormous number of mines used can be gathered from the fact that in the large minefields in home waters alone, there were some 34,300 mines laid in the Dover area and Narrows of the North Sea (including 9,500 in the Sir Roger Keyes' Folkestone to Gris Nez barrage); the Bight absorbed some 43,000 and the Northern barrage 70,117. There can be little doubt that too little importance was attached to the mine in British pre-war views on naval strategy. There was too great a tendency in those days to interpret war at sea wholly in terms of hitting a target at long ranges with a heavy gun. No modern battleship was sunk in this way, and of the various classes of British ships lost during the war, fewer were sunk by guns than by mines—namely 5 battleships out of 13 (38%), no battle cruisers out of 3, 1 cruiser out of 13 (7·7%), 2 light cruisers out of 12 (16·5%), 5 sloops out of 18 (28%), 20 destroyers out of 64 (31%), 4 submarines out of 54 (7·5%). In the destruction of German submarines they played a more important part. Of 200 submarines the loss of 43 (or 21·4%) was due to mines, and as one-fifth of those unknown (4 out of 17) may be attributed to the same cause it may be accepted that 23% of German submarine losses were due to British mines. (A. C. D.)

**MINING** (*see* 18.528).—While the standard methods of extracting ore from vein deposits, by overhand or underhand stoping, changed little during the period 1910–20, a more definite classification than was formerly possible grew up respecting the application of these methods to given local conditions. Comparatively thin veins, with a steep pitch (dip), are developed by a series of drifts or gangways (levels), and above each of these overhand stopes are opened for extracting the ore, the working being advanced upward and forward. The broken ore is run through chutes (mills or passes) to the level below, in which it is conveyed by small hand-trammed cars, or by mechanical haulage, to the shaft or through a tunnel to the surface. For somewhat thicker veins, especially those with a steep dip, underhand stoping is occasionally employed, most of the holes for blasting being then drilled downward, and the advance is forward and downward towards the haulage level. For flat veins or bedded deposits breast stoping is used, the details of which resemble those of underhand stoping. In all of these methods, the roof of the deposit (hanging wall) is supported by pillars of ore, by timber posts or stulls, by square-set timbering, or by masses of waste ore and rock (filling) carried by stulls. Sometimes stopes are completely filled with waste rock.

*General Classification of the Above Methods.*—Narrow, steep-dipping veins: open, overhand or underhand stopes, the roof being supported by timbers or pillars. Wide, steep-dipping veins: open, underhand stopes, with pillars or ore. Flat beds or veins: breast stoping, or room-and-pillar working, in which little or no timber is used.

For full illustrated details and variations, see *Mining Engineers' Handbook*, pp. 493–598 (John Wiley & Sons, 1918).

*Shrinkage Stopes*, a variety of overhand stopes, for both narrow and wide, steeply dipping veins, have in recent years been more widely employed than formerly. In them the broken ore is allowed to accumulate until the stope is completed, thus making timbering or other artificial support for the walls of the stope unnecessary. Since rock when broken increases in bulk, from 25 to 40% of the ore is drawn from the stope as it advances to leave room at the top for the miners, who stand on the broken ore while drilling. Obviously, this method is applicable only when the inclination and width of the vein are great enough to allow the broken ore to slide down freely on the stope floor (footwall). Finally, after all the ore has been drawn off, the stope is allowed to cave, or is filled with waste. Shrinkage-stoping is often employed in connexion with other methods in the same deposit.

*Caving Systems.*—The prototype of these, long employed in certain British iron-mines, is known as the North of England caving system. In the United States caving was first used for mining the soft iron ores of northern Michigan. More recently, it has been extensively applied to the iron deposits of the Mesabi district, Minnesota, and to some large copper deposits of the south-western part of the United States. The most important requirements for the successful application of caving methods are: (1) massive deposits of relatively cheap minerals; (2) ore-bodies of large horizontal dimensions, overlaid by a capping varying in character from earthy soil or glacial drift to firm rock; (3) large-scale work. There are three distinct methods: top slicing, block caving and sub-level caving. The salient features of all are: (*a*) horizontal subdivision of the ore-body into floors; (*b*) subdivision of each floor into small sections (slices or blocks), which are mined separately; (*c*) delivery of the broken ore through raise-chutes to the haulage-ways below, and thence to the hoisting-shafts; (*d*) as the ore is removed, the overlying capping must gradually cave and settle. Formerly, a method called "bottom slicing" was occasionally employed, in which the mining of the successive floors was begun at the bottom of the ore-body, instead of the top, as in top slicing. It is now almost obsolete. The decade 1910–20 was marked by a much wider use of the slicing and caving methods, especially for mining large low-grade deposits of disseminated copper ore. More deposits of this type were developed and worked in very recent years than ever before. Many variations in practice and changes in details were introduced to suit the given dimensions of ore-body, its depth below the surface, and the physical and mineralogical character of the ore and capping. All this brought a more definite understanding of the applicability and limitations of the caving systems, as determined by the existing local conditions.

Some prominent examples of the newer mines, in which different forms of slicing and caving have been adopted, follow.

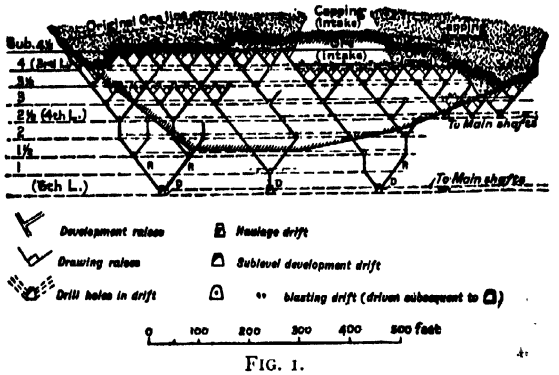

FIG. 1.

*Inspiration Mine, Arizona.*—The ore-body is a massive deposit of disseminated sulphide of copper (chalcocite), containing about 100,000,000 tons of low-grade ore, and overlaid by a valueless capping, 30 to 350 ft. thick. A variation of the caving system is used, known as "block-caving." The ore-body is intersected at vertical intervals of 150 ft. by main haulage levels, connecting with the hoisting shafts (fig. 1). Above the haulage levels are long chute-raises, inclined at 50° to the horizontal, from which numerous short secondary raises ("finger-raises") are driven to a system of sub-level drifts, 35 ft. apart vertically and 50 ft. horizontally. The ore developed by each series of sub-level drifts is thus divided into relatively small "blocks," which are undercut and broken by blasting out the supporting pillars between the sub-level drifts. The broken ore is drawn down through the branching finger-raises underneath, into the main raises, and thence to the haulage levels, the flow being controlled by gates. As the upper part of the ore-body is thus removed, the overlying capping caves in on top of the solid unmined ore below. (For full details, see *Trans. Amer. Inst. Mining Engs.*, vol. lv., p. 218.) Block-caving, conducted similarly to that of the Inspiration mine, is also used by the Ohio Copper Co., Bingham, Utah, and the Nevada Consolidated Copper Co., Ely, Nev. (Peele, *Mining Engineers' Handbook*, pp. 640–2).

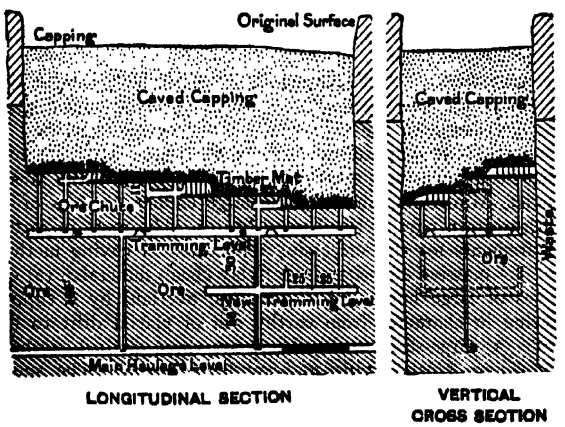

FIG. 2.

*Arizona Copper Co.*—A top-slicing method (fig. 2) is applied to large bodies of soft ore, carrying 2 to 4% copper. A main haulage-way is driven near the bottom of the ore-body, and above it are intermediate working levels, 50 to 60 ft. apart vertically. These comprise a rectangular system of tramming drifts and crosscuts, from which chute-raises are made into the ore above at 25 to 30 ft. intervals. Starting from the tops of these raises, horizontal slices of ore, 7 to 15 ft. thick, are blasted out and the broken ore is run down through the raises to the tramming level. Thence it is conveyed to the nearest main raise, connecting with the haulage-way below. (For details of the slicing operations and the manner in which the overlying capping caves as the successive slices are removed, *see* 18.532.) The modifications of the top slicing system noted above are chiefly in the mode of laying out the main haulage-ways and intermediate tramming levels, and in making raises from the latter at such short intervals as to minimize the labour cost of handling the broken ore mined in the slices. In one of the Arizona Copper Co.'s mines, a further saving has been effected by omitting the tramming levels and the small raises from them to the slices. A main drift is driven longitudinally through the axis of the ore-body, just below the capping, and from it at right angles are crosscuts, 40 ft. apart, to the walls. The panels of ore between the crosscuts are sliced back from the walls of the ore-body towards the main drift. On each side of the latter a pillar is left, which is finally sliced back from its end, in completing a floor. While one floor is being mined, the next, 11 ft. below, is in preparation. This method of panel slicing has recently been adopted successfully in the Herman gold mine, California. Overhand stoping, with square-set timbering, was formerly employed. The vein dips 45° to 60°, and the panels are laid out at an inclination of 52°, across the ore-body. Top slicing is also used in many other copper-mines containing massive deposits of low-grade ore, for example: Cumberland-Ely, Nev.; Cananea, Mexico; Miami, Ariz.; Bingham, Utah, and mines of the Calumet & Arizona Mining Co., Arizona. At the last-named property, the older caving method has been replaced by a modification called the Mitchell top-slicing system, which is found economical in reducing the amount of shovelling required. (For illustrated details, see Peele, *Mining Engineers' Handbook*, pp. 619, 620.)

*Other Variations.*—In a number of important mines working large ore-bodies, special conditions have been dealt with by combining two or more of the methods referred to above. Examples of such practice are to be found in the mines of the Braden Copper Co., Chile; New Jersey Zinc Co., Franklin, N.J.; Utah Copper Co. (Boston mine); Ray Consolidated Copper Co., Ariz.; Homestake Gold Mining Co., S.D., and of the De Beers Mining Co., S. Africa. In most cases, operations begin by shrinkage stoping, after which the intervening pillars are mined by top slicing, block-caving or sub-level caving. The aim is to obtain a high tonnage extraction from the ore-body; that is, to minimize loss of ore left in permanent pillars or through mixture with waste material.

*Stripping Superficial Ore Deposits.*—Though this old mode of attacking shallow deposits of large horizontal area underwent little change, it was oftener resorted to in the decade 1910–20 than previously, and, with good organization and plant, was being applied to deeper ore-bodies than formerly were considered minable by stripping operations.

*Standard Methods.*—Standardization of methods of developing and working mines would undoubtedly promote efficiency and economy of operation. Beds of coal, owing to their comparative uniformity of geological occurrence, can be worked to a considerable degree by standardized methods. The same is true of some regular bedded deposits of the base metals. But, as metalliferous deposits in general vary greatly in their physical characteristics, standards of practice in working them are less readily attainable, and any rules that may be formulated are subject to many exceptions. (To illustrate this matter, see a useful discussion by C. A. Mitke of the "Mining Methods of the United Verde Extension Mining Company, Arizona," *Trans. Amer. Inst. Mining Engs.*, vol. lxi., p. 188.)

In many of the particular operations of mining, there has been of late a stronger tendency toward standardization of details. A standard, in this sense, may be defined as a well-tested and approved mode of doing a certain piece of work. For example, some large mining companies have adopted standard "rounds" of holes for shaft-sinking, drifting, crosscutting, raising and stoping. The foremen and shift bosses are furnished with instruction sheets which specify the position, angle to the drilling face, depth, and charge of explosive, for each hole of the round. The miners are required to follow these instructions instead of doing their work in accordance with their own individual ideas. The adoption of standardized methods has been assisted by the greater attention now given to efficiency engineering. Many large mines maintain "efficiency engineers," whose duty it is to study in detail the performance of both men and machinery, thus aiming to improve the quality and amount of work done, and so reduce cost. Directed toward this end also are the recent movements inaugurated by several large mining companies to give their employees systematic instruction in the best methods of doing their work. This benefits the employer as well as the employee. Thus, an education department has been organized by the Phelps-Dodge Corp., of New York, which operates a number of mines in the south-western part of the United States. Series of lectures are delivered on practical mining topics, followed by examinations. The North Butte Mining Co., of Montana, has also given much attention in the last few years to instructing its employees and standardizing the details of many of the underground operations. The cost of maintaining these education departments is considerable, but it is amply justified by the results obtained. A wholesome spirit of rivalry is encouraged amongst the miners and their ambition is aroused; hence, better work is done, the *moral* of

the whole force is raised, and more cordial relations are established between the employees and the mine management. For certain mining appliances and machines standard designs grew commoner. There are clearer distinctions as to the applicability of different types of hoisting engines, compressors, ventilating fans, coal undercutting machines, mine cars, ore-chutes, etc.

*Blasting.*—Explosives for blasting rock and ores underwent little change during 1910–20 in general composition, but tests supplied valuable data respecting the disruptive and propulsive forces and the sensitiveness of the various types and grades of dynamite, so that their suitability for different kinds of service is better understood than formerly. Explosives for coal-mines, especially mines in which dangerous gases or dust occur, must be so constituted that ordinary charges will not produce a flame of sufficient intensity and duration to ignite explosive mixtures of gas and air. These comprise the tested " permissible explosives," lists of which are published in coal-mining countries and revised from time to time, to keep them up to date. In Europe their use is required by law. In the United States the lists appear in publications of the Bureau of Mines (a branch of the U.S. Geological Survey). The bureau can only recommend them, though legal requirements exist in some of the individual states. The permissible explosives have certain characteristic ingredients: (*a*) ammonium nitrate; (*b*) salts containing water of crystallization, which, being liberated and vapourized by the heat of the explosion, reduces the flame temperature; (*c*) organic nitrates other than nitro-glycerine, *e.g.* nitro-starch; (*d*) nitro-glycerine, mixed with free water or an excess of carbon. It was formerly assumed that nitro-glycerine compounds and other detonating explosives were not suitable for collieries, because, due to market requirements, excessive shattering of coal is undesirable (except for coke-making); but low-strength, " short-flame " dynamites are now being satisfactorily used. While no explosive can be absolutely safe in gassy mines, those in the permissible lists are relatively safe. As the standard test, an explosive is accepted for the list when a charge of 680 grams (1½ lb.) does not ignite gas or coal dust; it is not accepted if a charge of 250 grams does cause ignition. In 1912, the permissible list of the U.S. Bureau of Mines comprised 96 kinds and grades of safety explosive; in June 1920, the number had increased to 175. The United States is the largest user of permissible explosives, the quantity consumed having nearly doubled in 1912–20.

Blasting methods were improved by the introduction (1909–10) of " delay-action " electrical fuzes.[1] In work like tunnelling and shaft-sinking, where rounds of holes are best fired in volleys, these special fuzes save time, as the miners need not return to the working place after each volley to prepare for the next blast. The entire round is wired, as if all the holes were to be fired simultaneously, and there is but one application of the current. The groups of holes explode successively, in the desired order and at intervals of about one second, by using " no-delay " fuzes for the first group and " first-delay " and " second-delay " fuzes for the following groups. Construction of delay fuzes: The platinum bridge in the cap shell, between the terminals of the fuze wires, is not embedded in the fulminating charge itself, so as to explode it directly, but ignites a short piece of slow-burning ordinary fuse, which in turn explodes the fulminate. This gives a delay interval depending on the length of ordinary fuse used. Another new device for the same purpose is the electric fuze-igniter. A special electric cap contains a small charge of fine-grain black powder, beyond which is a piece of ordinary fuse, with a cap on the end to be placed in the dynamite cartridge. For blasting with black powder, no cap is put on the end of the ordinary fuse. Electric squibs, with paper instead of copper shells, are now used to some extent for blasting with black powder.

*Mine Hygiene.*—Improvements made in the years 1910–20 were chiefly in five directions: (1) better ventilation of mine workings; (2) enforcement of dust-prevention regulations; (3) introduction of new types of blasting explosives, so constituted as to minimize the quantity of deleterious gases evolved; (4) adoption of precautions aiming to produce more perfect combustion of explosives, and so reduce or prevent the formation of the poisonous carbon monoxide; (5) study and better understanding of special miners' diseases and their treatment.

Formerly, artificial ventilation by fans or blowers was provided only for collieries, to dilute and sweep out gases emanating from the coal, and to remove the explosive coal dust. In recent years, mechanical ventilators have been increasingly used for metalliferous mines also. About the year 1902, the high mortality amongst the miners of some districts began to attract attention. Investigation showed that acute lung trouble (" miner's phthisis " or silicosis) is caused by inhaling silicious dust from drilling in dry rock or ore. In 1903, a Government commission was appointed to study the conditions in the Transvaal gold-mines. Their report led to a demand for better ventilation of the mine workings, and the adoption of water-spraying devices to allay the dust during the operation of drilling. Revised and more stringent regulations went into effect in 1913. Other governmental investigations were made in Cornwall, Australia, and New Zealand, and in the United States by the Bureau of Mines. In 1911, one of the large gold-mining companies in the Transvaal, the Rand Mines (Ltd.), established a department of sanitation, to deal in general with miners' living and working conditions and diseases. The department's activities now cover a large number of the mines of the district, employing between 55,000 and 65,000 men. Marked benefits have resulted from this widespread interest in mine hygiene. For example, tests of the gases from blasting explosives have revealed the extent to which they may vitiate mine air. One pound of standard dynamite produces about 10 cub. ft. of gas, which, due to incomplete detonation, often contains 25 to 30% of carbon monoxide. Since, for safety, this actively poisonous gas should be diluted to about 0·01 of 1%, it is evident that natural ventilation can not always be relied upon, and mechanical ventilators have been installed for many metalliferous mines. In recent years, several new types of high explosives have been introduced, so compounded that they produce much less carbon monoxide and methane ($CH_4$) than the standard (" straight ") dynamites. They are therefore particularly useful in poorly ventilated mine workings, as headings where there can be no through ventilation. Furthermore, there has been increased insistence on the use of high-strength caps or detonators, since imperfectly detonated dynamites of all kinds produce an excessive amount of carbon monoxide.

*Explosions in Coal-Mines.*—Advances have taken place in the appliances for fighting mine fires, and the modes of preventing and dealing with gas and dust explosions in collieries. Coal-dust explosions are generally much more serious in bituminous than in anthracite mines. An explosion of anthracite dust does not appear to be self-propagating. Most explosions in anthracite mines are of gas, sometimes aided by presence of dust. Many investigations of coal-dust explosions have been made in Europe since 1880, but some of the phenomena attending their initiation and propagation have long been imperfectly understood. Much light was thrown on the subject by the elaborate experiments conducted by J. Taffanel, at the Liévin testing station, France (beginning in 1907), and by the U.S. Bureau of Mines at their testing plant and their Bruceton experimental mine, near Pittsburgh (since 1909). Amongst the facts demonstrated are: (*a*) The blasting of a single hole, charged with long-flame explosive (black powder or ordinary dynamite), may cause the ignition of coal dust; (*b*) respecting the initiation of an explosion, if enough dry coal dust is present, it is immaterial whether the air at the point of origin is quiescent or moving in either direction; (*c*) quantities of dust as small as 1/5 oz. per cub. ft. of space (or 1 lb. per linear ft. of an ordinary gangway) will propagate an explosion; (*d*) in presence of sufficient dust, an explosion may be produced at will in a gangway, even when the roof, sides and floor are wet to the touch; (*e*) the force of a coal-dust explosion usually increases in violence as it is propagated through a mine working, and may reach its maximum after travelling 500 to 800 ft. from the place of origin; (*f*) pressures as high as 120 lb. per sq. in. have been measured at right angles to the direction of movement of an explosion, the pressure in the line of advance being doubtless much greater.

Rock-dust barriers, for checking or preventing the propagation of coal-dust explosions, were invented by J. Taffanel and modified by G. S. Rice, of the U.S. Bureau of Mines. They consist of series of wide shelves, set across the mine gangway near the roof, each loaded with rock dust. In case of an explosion the shelves are tripped mechanically by the advance force waves, being set to operate at certain air velocities or pressures produced by the explosion. From two to three tons of rock dust are thus discharged in a dense cloud, in front of the advancing explosion wave, and, mixing with the coal-dust-laden atmosphere of the gangway, prevent propagation of the explosion. Several forms of dust barrier are used for different local conditions. Gas helmets and oxygen breathing-apparatus, long used in mine rescue work, were considerably improved after about 1913. Interest in these matters was stimulated by the introduction in several countries of Workmen's Compensation Acts (which hold the employer responsible for injury or death due to accident), and also by the use of poisonous gases in the World War.

*Hoisting Engines.*—Power plants (generally hydro-electric) have been established in many mining districts, and supply electric current at cheaper rates than are possible for equivalent steam power. Electric-driven hoists are consequently used in much greater numbers than formerly. Their control mechanism is now so perfected that they are as manageable as the best steam hoists. The large variations in load, unavoidable in hoisting operations, and very disadvantageous for electric transmission of power, are successfully dealt with by the " equalizing systems " of hoisting, the first of which, the Siemens-Ilgner, was introduced just previous to 1906. Modifications of it, based chiefly on the mode of control, are the Westinghouse and the Ward-Leonard. The design and operation of all of these plants are based on the principle that, when a motor receives electric current, it will deliver mechanical power; conversely, when driven by mechanical power, the motor becomes in effect a generator and furnishes electric current. The alternating current usually supplied to a mine is first reduced to about 500 volts, and then goes to a motor-generator set, comprising a shunt or induction motor, which drives a direct-current generator and a heavy

[1] The spelling " fuze " is used for electric blasting, " fuse " for ordinary blasting.

fly-wheel, all on a common shaft. This set is in constant motion, though not at constant speed. From the generator the current goes to a hoist motor, which drives a pair of drums on the drum shaft. At the beginning of a hoisting cycle, the hoist motor receives current from the motor-generator set; but, after the descending cage has reached a point where the trip can be completed by the weight of the rope, the hoist motor is driven by the drum, and therefore supplies current to the generator of the motor-generator set. Thus, part of the recovered power is stored in the fly-wheel, while the remainder is expended in driving the induction motor as a generator, thereby causing it to deliver current to the external circuit or power service. The fly-wheel cuts down the peaks of the load curve. Since 1915, a number of these plants have been erected; they are costly and suitable only where the hoisting is nearly continuous and high peak loads are heavily penalized in the power service.

*Underground Haulage.*—For locomotive haulage, the electric trolley system was in 1920 still first in importance; next to this were the compressed-air locomotives. Storage-battery locomotives, though invented many years ago, were rarely used until about 1911, and in 1920 were employed to a limited extent only. Their construction is simple, and, as they carry their power with them, they have the advantage of being able to operate wherever track is laid, without the necessity of stringing trolley wire. They are best suited to short hauls and light service, as for gathering individual cars from the working places and making them up into trains on the main haulage lines. Maximum speed is about 5 m. per hour, and easy track gradients are necessary. Their chief disadvantage is high first cost. A few combined trolley and storage-battery mine locomotives have been built, but they are unlikely to have a wide application. Gasoline locomotives were introduced before 1905, but were not much used until about 1912. Like storage-battery and compressed-air locomotives, they have the advantage of carrying their own power. Ordinary speeds range from 4 to 10 m. per hour. Although reasonable in first cost and running expenses, gasoline locomotives can be employed underground only where there is abundant and active ventilation, because their exhaust usually contains enough carbon monoxide gas to require a high degree of dilution. Their consumption of gasoline at full load is, say, 0·7 to 1·2 lb. per H.P.; considerably more at half speed and load.

*Shovelling Machines*, for loading broken coal or ore underground, were introduced about 1907. The first was the Thew machine, a dipper shovel of small size, operated by electricity or compressed air and suitable for use in stopes in a flat-lying deposit, or in a tunnel. A later design, the Myers-Whaley, consists of a large scoop, which is thrust into the pile of broken ore or rock, then lifted and dumped backward onto a short travelling conveyer, for loading into a mine car in the rear. This machine occupies but little space, and can be used in a large mine tunnel or drift. In 1915 two of them were installed in the ends of a long haulage drift, 14 ft. wide by 10 ft. high, in the Crown Mines, Transvaal. The Halby shoveller resembles the Myers-Whaley. Other machines, especially for loading coal, have recently been invented, and are undergoing working tests. Mechanically considered, shovelling machines are unquestionably successful. Interest in them has been stimulated by the greatly increased rates of wages now prevailing in most mining regions. It has been proved, however, that, where wages are low, they cannot compete with hand loading.

*Machine Drills* underwent important changes during 1910–20, especially in the development of the "hammer" drills, which for many kinds of service have largely replaced standard types of piston machines. In the hammer drill, the bit is held stationary in the front end of the machine, and is struck a rapid succession of blows by the reciprocating piston-like hammer. As the bit does not reciprocate, its cutting edge being always in contact with the rock, except during the slight rebound caused by each blow of the hammer, the sludge or cuttings tend to pack in the bottom of the hole. Hence, unless some automatic means be provided for keeping the hole clean, part of the useful effect of the hammer blows would be lost. To keep the hole clean while drilling, most hammer drills use hollow bits; that is, there is a small hole longitudinally through the axis of the bit. Through this hole, a jet of compressed air or water is discharged in the bottom of the hole, thus driving out the cuttings. When compressed air is used, and the rock is dry, the dust discharged from the mouth of the hole is annoying and hurtful to the drill-runner. Hence, most hammer drills use a water jet. The water is delivered under pressure from a 15-gal. to 18-gal. tank, through a short length of hose. Pressure in the tank is produced by connecting it by another hose with the compressed-air pipe.

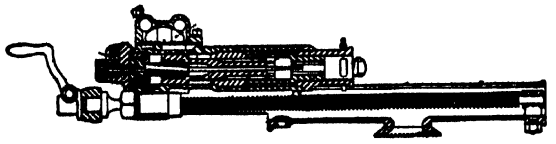

FIG. 3.

Hammer drills, made by all the principal rock-drill manufacturers, are of three general forms: (*a*) Large machines (fig. 3), corresponding in size and weight with ordinary piston drills, mounted on tripod or column and used for the same kinds of work; (*b*) the small D-handle and cross-handle drills for making holes pointing downward, as in shaft-sinking (fig. 4); (*c*) machines having an automatic air-feed standard, used chiefly for holes directed steeply upward, as in most stoping operations (fig. 5). Machines of classes (*b*) and (*c*) have the advantages of lower first cost, of being operated by one man instead of two, and of eliminating the time lost in cleaning out the hole and in "setting up," as for the standard piston drills and class (*a*) hammer drills. In most rocks and ores these hammer drills, therefore, do faster work than piston drills.

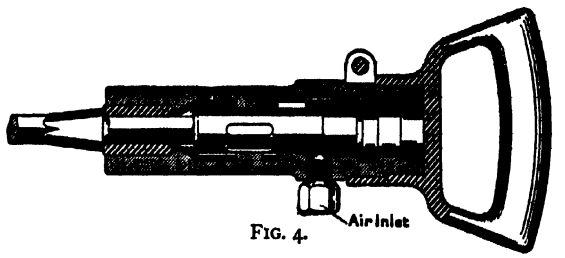

FIG. 4.

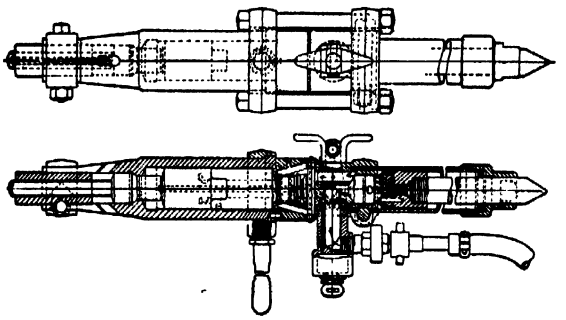

FIG. 5.

*Deep Boring.*—In recent years, for prospecting by boring, there has been a great increase in the use of the "churn drill"; that is, a drop drill, suspended by a rope from the operating machinery on the surface, and similar in many respects to the standard oil-well drilling plant. For boring holes deeper than, say, 75 or 100 ft., the churn drill has practically superseded the old method of rod-boring, formerly common in Europe. In general, for deep boring, the oil-well "rig," the churn drill and the diamond drill divide the field among them. During the decade 1910–20, many oil and natural gas wells were bored to depths of 4,000 to 5,000 ft., and a few exploratory holes (in Pennsylvania and West Virginia) reached depths of 7,000 to 7,350 feet. For holes of a few hundred ft. in depth, and when cores are desired, the rotary "shot-boring" method, based upon the old Davis Calyx drill, also came into wider use. The apparatus consists essentially of a line of hollow rods, carrying a bit, say, 3 in. diameter by 10 in. long, with a narrow slot cut in its lower edge. At intervals during boring, a quantity of small steel shot is fed down through the hollow rod. The shot distribute themselves between the outside of the bit and the walls of the hole, between the inside of the bit and the core, and under the lower edge of the bit. Due to the rotation of the bit, the shot are caused to roll forcibly with a milling action against the rock, which is thus ground away. (For full details, see Peele, *Mining Engineers' Handbook*, Sec. 9, Art. 16.)

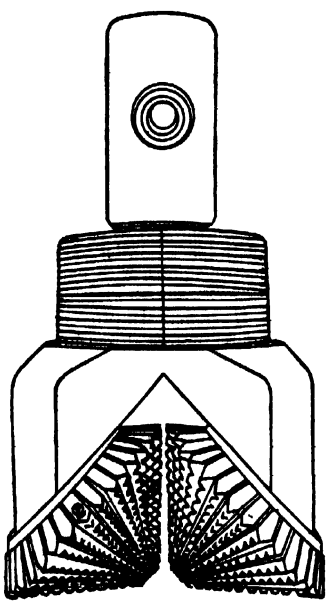

FIG. 6.

For rotary boring in unconsolidated strata overlying the solid rock, the "fish-tail," with two cutting edges resembling those of a large carpenter's auger, has long been employed for oil and gas wells. But

this bit wears rapidly if boulders or interbedded strata of shale, etc., be encountered in the gravels and clays. In 1908 the Sharp and Hughes cone-bit (fig. 6) was introduced to replace the fish-tail bit for boring in rock, and it has been widely used in some of the petroleum and natural gas-fields. The bit consists of a pair of hardened steel cones, with serrated or toothed surfaces, revolving on bronze bearings. As the drill rod rotates, the cones roll under pressure upon the rock, crushing and chipping it away. When dull, the cones are readily replaced. These bits in some cases bore as much as 100 ft. of hole in 24 hours. In boring oil wells through soft strata or shattered rock, trouble is often caused by the caving of the sides of the hole before the lining or casing pipe is put in. To overcome this difficulty, " mud-laden " water may be used in the boring operations instead of the ordinary wash-water. Almost any finely divided, clayey material that will remain in suspension for a considerable period of time may be employed. The mixture of mud and water should have a specific gravity high enough to afford a counter-pressure that will support the walls of the hole; a specific gravity of about 1·33 is usually sufficient. The pressures in the bore-hole are thus kept in approximate equilibrium until the hole is lined with pipe (casing), or until screens can be set in the oil-bearing strata and cemented in place. This method was introduced in Europe, about 1895, for sinking cylindrical mine shafts in unstable, water-bearing soil by boring. About 1901 it was adopted for boring oil wells in Texas and Louisiana, and since 1906 has been successfully used in a large number of cases.

**MINING, MILITARY** (*see* 10.714).—Until the invention of explosives military mining resembled ordinary mining, in that it consisted of driving galleries or tunnels under the enemy's defences, either with the object of penetrating to the interior of the place attacked, or of undermining the walls and causing them to collapse. The latter method was probably used by Joshua at the siege of Jericho, while he distracted the attention of the defenders by a military promenade round the walls.

When the miner was put in possession of gunpowder he used it first for blowing up the enemy's defences, and later for destroying his galleries and for making craters as points of departure for trenches. The term " mine " in military language thus came gradually to mean, not a system of underground galleries as in civil life, but a charge of explosive operated underground or under water.

The position of military mining in 1910 is described in 10.716; contrary to expectation the first events of the World War seemed to indicate that mining was unnecessary, because the effect of the new heavy howitzers proved to be sufficient in themselves for the reduction of fortresses. But when the armies were settled down in opposing systems of trenches the heavy howitzers lost their preponderating rôle, and in the deadlock that followed old-fashioned methods reasserted themselves for trench warfare, such as grenades, trench mortars, and mining.

On the British front mining was started by the Germans. Before the end of 1914 there were two definite cases of mines under British trenches, and shallow mining systems were started in reply. It soon became evident that there was a probability of mining on an extensive scale, and that the existing R.E. units would be quite unable to supply the necessary personnel. It was proposed that coal-miners should be specially enlisted for the work, and their first detachment arrived in France in Feb. 1915. The formation of " tunnelling companies " followed, and during 1915 there was mine warfare all along the front.

In the early phases mining was chiefly a question of local efforts, partly defensive to counteract enemy mines, and partly directed against close objectives such as strong points in the enemy's trenches or a sniper's post. The mine systems were shallow, being rarely deeper than 20 feet. By June 1915 there was an enormous number of them, and the demands made upon the tunnellers could not be met. The need of a centralized control began to be apparent, not only to coördinate the local schemes, but in order that plans of larger scope might be developed in harmony with strategical ideas. Already in Aug. 1915 the first deep-mining system had been started, against Hill 60, with an object which was more than local; and questions of organization, of instruction, of intelligence and provision of stores all made direct touch with G.H.Q. essential.

Accordingly in Dec. 1915 a mining staff was appointed with an inspector of mines at G.H.Q., and a controller of mines at each army headquarters. The duties of the inspector of mines were defined as follows:—

(*a*) Preparation, under the instruction of the general staff, of mining schemes which were intended to have a bearing on the principal operations of the campaign, and examination of mining schemes prepared by the armies.

(*b*) Inspection, for the information of the commander-in-chief, of the progress of all mining work.

(*c*) Advising the engineer-in-chief on general questions affecting the personnel, organization and equipment of the tunnelling companies.

The officers of the tunnelling companies were chiefly mining engineers drawn from all parts of the world, many of whom had already had experience in the trenches. The men included, besides ordinary coal-miners, a number of specialists known as " clay kickers." These men worked on their backs with cutting tools fastened to their feet. Each man was strapped on a plank which was pushed forward as his excavation advanced, and in this manner, in good ground, he was able to work in a very small gallery and make rapid progress.

Since a good deal of unskilled work was required for removal of soil, transport of materials, etc., a number of infantry were attached to the tunnelling companies. Thus a tunnelling company on the higher establishment had 569 officers and men, and with attached infantry might be 1,000 strong. By the end of June 1916 there were 25 imperial companies and seven overseas companies at work, with a total strength of about 25,000 of all ranks. A new departure was the attachment of geologists to the mining staff; their advice was especially valuable in connexion with the water levels, which in chalk country varied as much as 30 ft. between summer and winter. In the German army the arrangements were much more elaborate, each army having a complete geological staff.

In addition to this it must be noted that for the first time in history the British army had immediate access to scientific brains at home, and could utilize at a moment's notice the most advanced manufacturing facilities of the country. The effect of this showed itself particularly in the development of listening apparatus. In former wars the human ear unaided had to listen for the sounds of the enemy working underground, and estimate his distance and direction; in this war specialists in England were able to turn their attention to the production of listening apparatus as soon as the requirement was made known.

It naturally follows that the headquarters staff, with a very large and highly skilled personnel at their disposal, unlimited resources, and the prospect of a long period of trench warfare, began to conceive operations far in advance of anything that had been contemplated in war.

Shallow mine systems had still to be continued to protect the British trenches, but at the same time deep galleries were started from 50 to 100 ft. below the surface directed against special objects. Naturally the two systems were sometimes worked together. The operations at The Bluff, between St. Eloi and Hill 60, illustrate this. At this point there was a prolonged German offensive from Oct. 1915 to Sept. 1916. Working with a shallow system the Germans blew a large crater in Jan. 1916, which caused many casualties and temporarily destroyed the British

position. In July 1916 they blew four mines behind the British trenches, making a crater 150 yd. by 50 yd. The British infantry had been warned by the mine officers; there were few casualties, and a barrage having been arranged for, the Germans could not secure the position. Just before this the British had started a deep gallery about 100 ft. below the surface. Working from this, and after some fighting in shallow systems, they blew four charges, totalling about 10,000 lb.

"Ten minutes before the blow two officers and eight men of a tunnelling company lay out in a shallow hole in a small crater which had been calculated as directly above the enemy workings. They started to dig down immediately after the blow, and broke through to the enemy gallery by midnight, which they found tamped with sandbags. These were all removed by 10 A.M. next morning, and about mid-day the galleries were entered by men wearing Proto apparatus—a complete survey was made, and 700 ft. of undestroyed enemy gallery, together with much apparatus, was found to have been captured. The enemy system was connected to our own shallow workings, and for the first time in its history The Bluff was reported as absolutely safe from underground attack.

"This final operation was a good example of a successful flank attack; our gallery was well below the enemy, and we succeeded in getting under him and along his front without being discovered."

The Somme offensive in 1916 was an example of mining conceived and executed in connexion with an important attack, the plans being worked out in April, and a programme laid down. The underground work for this attack included mines for destruction of enemy works, galleries to provide advanced emplacements for machine-guns and Stokes' mortars, to be developed into communication galleries, and galleries for emplacements, ammunition, etc., only. There were nine mines containing altogether nearly 200,000 lb. of high explosive. They gave excellent results. The largest, having 40,600 lb. of ammonal, was placed at a depth of 75 ft. at the end of a gallery 300 yd. long; and it destroyed a salient covering 100 yd. of German line. The special point about the "galleries to provide advanced emplacements" was that a tunnelling officer was stationed at the end of each gallery, whose duty it was to break through the top of the emplacements for mortars and machine-guns, and also to break out at the end of the gallery to start the communication trench. Of the galleries for communication purposes only, 16 were connected up with the German lines. The methods of communication were three: by stepping up to the ground level and breaking out and digging; by placing a charge in a bore hole and blowing a crater in the enemy's trenches, then breaking out from the gallery into the crater, and thence into the German trenches; and by making a trench with a "pipe-pusher." Galleries for emplacements to ammunition depots were successfully broken through at the top, and the galleries were used at first for signal cables, runners and ammunition carriers; later for transport of wounded. This operation proved the value of these underground galleries in connexion with an attack.

In Sept. 1916, on the German side, large numbers of miners were sent home for industrial reasons, and mining activity was much reduced. The deep system controlled by G.H.Q., and directed against distant objects, was steadily pushed on, but the old shallow defensive systems were merely kept free of water and watched by listeners. The tunnellers thus set free were employed on what was practically a new development of mining, namely, construction of subways for infantry, and deep dug-outs.

By the end of Feb. 1917 nearly 20 m. of subways had been completed on the I., II. and III. Armies' fronts. In Sept. 1917 the Hohenzollern-Auchy subway system was completed, which made it possible to patrol 4 m. underground. At Nieuport subways and dug-outs were successfully made in spite of great difficulties with water and running sand. At the German attack a subway, not quite completed, east of the Yser, saved a considerable part of the infantry garrison.

The experience gained at the Somme was used to great advantage in preparing the attack of April 9 1917 on the Vimy ridge. In this case the mines, which were actually finished six months before the attack, were not of great importance, only two out of eight being used. The subways, which were made in three and a half months, were an interesting feature:—

"Twelve infantry subways from reserve line to assaulting trenches. These subways averaged half-a-mile long each, the shortest being 290 yd. and the longest 1,880 yd. They were 6 ft. 6 in. high and 3 ft. wide, with at least 20 ft. of head-cover, and were lit with electric light throughout, small lighting plants being installed in each subway.

"The subways were supplied with dug-outs, assembly chambers, trench-mortar and bomb stores, trench-mortar emplacements, water-tanks, dressing stations, signal offices, and in some cases brigade and battalion headquarters. They had numerous entrances and exits; the latter were broken out into advanced assaulting trenches on the last night, and the troops were able to file out into their assaulting positions through them. Maps on boards were hung at various points to show the position in relation to the surface. Tramways were laid in some of the subways, and these were found most useful for carrying up trench-mortar ammunition, stores and rations; signal cables were carried through the subways and signal stations were installed in them. The dressing stations, being dry and well lit, enabled the wounded to be easily attended to and kept in safety until they could be evacuated. Water-mains were also laid in some.

"Finally, the troops housed in the subways were able to rest in a safe, warm and dry place up to the time of the attack.

"The subways proved most successful, and, throughout, proof against bombardment, the only damage being done to some of the entrances. These were easily and quickly repaired by tunnelling company repair gangs, which were kept in each subway.

"The electric light in the subways was installed and run by the Australian electrical and mechanical mining and boring company. The lights were kept running throughout the whole operation without a breakdown. One plant actually ran 153 hours continuously. Ventilation was good, the only difficulty being in the case of gas attacks, when plenty of ventilation actually increased the danger. Specially appointed traffic officers (not tunnellers) were told off to each subway, and carefully trained beforehand in their duties."

In this connexion the use made of the Arras caves is interesting. These were underground quarries of the 17th century, and were discovered by chance. They were utilized as shelters for men by connecting them with the front-line subways. The main galleries were 6 ft. 6 in. high and 4 ft. wide. The caves and galleries were lit electrically throughout, and water-mains laid. The caves accommodated about 11,000 men.

At Messines (June 7 1917) the main feature was the enormous scale of the explosions, unprecedented in military history. The total charges were nearly 1,000,000 pounds. There were 20 mines distributed over a length of about 8 m., the greatest concentration being 500,000 lb. on 4,500 yd. of front, from Hollandscheschuur to Ontario Farm. The largest mine was 95,600 lb. of ammonal, at a depth of 125 ft., at St. Eloi. The longest gallery was 720 yards.

The first idea of a deep offensive in the Messines-Wytschaete area was in the summer of 1915, when a deep gallery was started against Hill 60. Various deep galleries were started in 1916, but the final scheme had not begun to take shape until the summer. Many mines were laid months before the explosion. From June 1916 to May 1917 the Germans were searching for mine systems and blowing deep camouflets with heavy charges. Galleries were damaged or flooded in many cases, but by strenuous work most of them were restored in time for the attack. A very large amount of dug-out accommodation was provided.

The use of these enormous mines, whose destructive effects could not be definitely foretold, was naturally a matter of anxiety, but they were certainly successful. Ludendorff writes in his memoirs:—

"We should have succeeded in retaining the position but for the exceptionally powerful mines used by the British, which paved the way for their attack . . . .

"All had been quiet and no sound of underground work on the part of the enemy could be heard at our listening posts. The mines must therefore have been in position long before.

"The moral effect of the explosions was simply staggering; at several points our troops fell back before the onslaught of the enemy's infantry."

This was the last great operation with explosive mines. After this the tunnelling companies were largely employed upon dug-outs and tunnelling. For instance, they made a number of subways through the canal bank near Boesinghe, for storage of material for bridging the canal. Subsequently they made approaches to the bridges by blowing gaps in the bank with bore holes. Other tunnellers were employed on roads and tramways.

During the German offensive in 1918 the tunnellers were used

for all sorts of purposes, including demolitions, and when the Allied advance began in August one of their most important duties was the removal of enemy land mines and booby traps.

*Advances in Technique.*—Probably the most important of these was in the development of "listening apparatus." In the fortress mining systems of 100 years ago an essential feature was the provision of listening galleries pushed out at regular intervals from the front lines of permanent defence galleries; but judgment of direction and distance of the enemy's workings depended entirely on the trained ear of the listener, which might easily be deceived. In the World War listening instruments were invented and employed for the first time.

After much experiment two types were approved, the geophone and the seismomicrophone.

The *Geophone* is on the principle of the stethoscope. A flat circular wooden frame contains mercury enclosed between two discs of mica. Two nipples on the edge of the frame provide for the attachment of ear-pieces with rubber tubes. Sound can be heard through the geophone about two and a half times as loudly as with the unassisted ear. A single geophone can do no more than magnify sound; for this purpose, however, it is very valuable, as it not only increases the distance at which enemy workings can be heard, but it helps the listener to distinguish between various sounds, such as picking, shovelling, talking, etc. With two geophones direction can be obtained, as follows: the two are placed at either end of a frame about 18 in. long, with a compass between them. To ascertain the direction horizontally the frame is placed on the ground and turned about until the sound is equally audible in both ears. The source of sound will then be in a direction at right angles to the line joining the two geophones, and can be plotted from the compass. If a bearing is then taken from another point, the intersection of the two will give the vertical line in which the source must be. To get the direction up or down, the geophones must be placed against the wall of the gallery. An example of the value of this method is given by Standish Ball:—

"A portion of our trenches had been captured by the enemy and heavily wired to repel our expected counter-attack. This was due to take place on the 27th of the month, and the miners were asked to assist in the enterprise and destroy the hostile wire. Owing to the short time available a shaft had to be sunk from the end of a sap, and the objective was reached on the 16th, just as the enemy were heard starting their mining operations. A geophone observation was immediately made, followed by further ones during the ensuing week. On the 24th the enemy were heard talking and laughing, without the aid of an instrument, only 6 ft. away, and to all intents and purposes on the point of breaking through. On examination of the previous observation, however, it was decided that the direction of his gallery was approximately the same as our own, and that he would probably pass along parallel to it. This is what actually happened, and the mine was blown successfully on the appointed day. If it had not been for careful and accurate listening the mine would have been blown prematurely and the success of the infantry attack jeopardized."

The *Seismomicrophone*, an electric detector, does not give direction, but saves man-power. "As many as 50 galleries might be connected up to the switch-board of a central listening chamber, situated in some quiet position behind the mining system. In the event of sounds being heard from the detector in any particular gallery a listener was immediately dispatched with geophones to investigate." This economy of listeners was very important, especially as the end of a gallery is often a very dangerous place.

The following table gives (in feet) the distance at which sounds can be heard by the various methods in chalk and clay:—

| Average Chalk | | | |
|---|---|---|---|
| Nature of sound | Naked ear | Seismomicrophone | Geophone |
| Picking . . | 125 | 175 | 250 |
| Shovelling . | 70 | 70 | 120 |
| Talking . . | 12 | 45 | 50 |
| Average Clay | | | |
| Picking . . | 50 | 70 | 120 |
| Shovelling . | 8 | 15 | 30 |
| Talking . . | 5 | 10 | 15 |

*Mine Rescue Work.*—One of the greatest dangers in mining has always been the presence in galleries of carbon-monoxide gas from the exploded mines. Owing to the quantity of mines blown and the large charges used this danger became very serious in 1915. "In six weeks one tunnelling company had 16 killed, 48 sent to hospital, and 86 minor cases treated at the shaft head and returned to the company billets." To meet this danger an instructor in the use of Proto apparatus was sent from England in June 1915, and schools for the teaching of rescue work were started.

The Proto apparatus consists roughly of twin cylinders of compressed oxygen, worn slung over the back, and supplying oxygen to a breathing bag containing caustic soda which absorbs $CO_2$ from the air exhaled. As this apparatus is in use in civil life it is not necessary to describe it here. The Proto set contains oxygen enough to last two hours. The Salvus apparatus is a lighter and more portable modification of the Proto, and is good for about half an hour. Oxygen resuscitating apparatus were also used. Apparatus special to the war were the mine stretcher, designed for dragging a man along a gallery and lifting him up a shaft, and a mine gas-testing set designed in the central laboratory at General Headquarters.

An officer of the R.A.M.C. having been attached to the staff of the engineer-in-chief for mine rescue work, the pathological aspect of the question was very thoroughly investigated.

*Bored Mines.*—These do not appear to have been much used in their original intention—that of pushing a thin pipe towards an enemy gallery, passing a small charge through it to blow a camouflet, and then filling the latter with a charge of 300 or 400 lb. of explosive. Larger bored mines with tubes up to 6 in. diameter were, however, used to some extent to make connexions. In some cases trenches were made in this way 14 ft. deep and 30 ft. wide. Trenches were also made by sinking bore holes from the surface and placing charges in them 4 ft. deep and 6 ft. apart. This method gave good cover in a very short time.

See *The Work of the Royal Engineers in the European War 1914–19*, section "Military Mining" (1921), which has been freely quoted in this article; also *The Work of the Miner on the Western Front, 1915–18*, by H. Standish Ball (Paper read at a meeting of the Inst. of Mining and Metallurgy, April 10 1919). The mine warfare on the western front is discussed from the German point of view in *Schwarte, Militärische Lehren des Grossen Krieges* (chap. ii.). (L. J.)

**MINNESOTA** (*see* 18.548).—The pop. of the state in 1920 was 2,387,125 as against 2,075,708 in 1910, an increase of 311,417, or 15% for the decade, as against an increase of 324,314, or 18·5% for the preceding decade. The total white pop. was 2,368,936, of whom 1,882,772 were natives and 486,164 foreign-born. Negroes numbered 8,809 and Indians 8,761. The density was 29·5 per sq. m.; 25·7 in 1910. The urban pop. (in places having over 2,500 inhabitants) was 1,051,593, or 44·1%, in 1920, 41·0% in 1910, and the rural pop. 1,335,532, or 55·9%; 59·0% in 1910. The following table gives the pop. and the percentage of increase of cities having more than 10,000 inhabitants in 1920.

| Cities | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Minneapolis . . . . . | 380,582 | 301,408 | 26·3 |
| St. Paul . . . . . | 234,698 | 214,744 | 9·3 |
| Duluth . . . . . | 98,917 | 78,466 | 26·1 |
| Winona . . . . . | 19,143 | 18,583 | 3·0 |
| St. Cloud . . . . . | 15,873 | 10,600 | 49·7 |
| Hibbing . . . . . | 15,089 | 8,832 | 70·8 |
| Virginia . . . . . | 14,022 | 10,473 | 33·9 |
| Rochester . . . . . | 13,722 | 7,844 | 74·9 |
| Mankato . . . . . | 12,469 | 10,365 | 20·3 |
| Faribault . . . . . | 11,089 | 9,001 | 23·2 |
| Austin . . . . . | 10,118 | 6,960 | 45·4 |

*Agriculture and Minerals.*—There were 178,478 farms in Minnesota in 1920, an increase of 14·3% since 1910. These farms covered about 30,000,000 ac., two-thirds of which was improved; the total value of farm land and buildings was $3,787,420,118. The state's two most valuable crops in 1919 were Indian corn, of which 84,786,096 bus. were raised, the value being $110,221,931; and wheat, 37,616,384 bus., the value being $88,398,508; the total value of the principal farm crops was $506,020,233. Live stock on farms was valued at $293,373,818. The northern part of the state is developing rapidly as a stock-raising and dairying section. About 60% of the output of iron ore in the United States is mined in the three great iron ranges of northern Minnesota. The Mesaba range, 110 m. in length, embraces 180 active mines. The Vermilion and Cuyuna ranges combined form an additional iron belt of about 50 miles. A total of 43,263,240 tons of ore, valued at $144,706,532, was shipped from Minnesota mines in 1918.

*Manufactures.*—In 1914 Minnesota ranked thirteenth among the states of the Union in the value of its manufactures. In the 5,974 establishments (not including hand industries) then existing, $354,434,177 was invested, 115,690 persons were employed, and products valued at $493,354,136 were manufactured. The value of the products had increased 20% since 1909. The state's five most important industries, in the order of the value of products in 1914, were the flour-mill and grist-mill, slaughtering and meat-packing, lumber and timber, dairy and creamery, and foundry and machine-shop industries. In 1919 some 300 flour-mills produced 29,337,131 bar. of flour; 811 creameries 143,176,204 lb. of butter; and 85 cheese factories 9,452,191 lb. of cheese. In flour and butter Minnesota's products exceed those of any other state. The total value of all dairy products in 1919 was $155,438,698. Since 1910 the slaughtering and meat-packing industries, centred at South St. Paul, have shown rapid growth. Because of the depletion of her forests Minnesota dropped from third place among the states in lumber manufacture

in 1900 to sixteenth place in 1920; but, though lumbering declined, timber manufacturing increased, so that Minnesota ranked in 1920 among the first states in the production of pulp wood, railway ties, fence posts, and telegraph poles. The foundry and machine-shop industries also have grown rapidly. A portion of the state's iron ore is now worked in huge iron and steel plants on the St. Louis river near Duluth, and farm machinery is manufactured increasingly.

*Transportation.*—The railway mileage in Minnesota Dec. 31 1919 was 9,230, an increase of about 9% since 1908. In 1918 there were 161·8 m. of electric line operated in the state. The U.S. Government completed in 1920 the construction of a dam in the Mississippi between St. Paul and Minneapolis, which by means of locks makes the latter city the head of navigation on the river. An attempt is being made to revive freighting on the river, between Minneapolis and St. Louis. With the growth of motor traffic, the demand for good roads has greatly increased, and the state was engaging in 1921 in road building on an extensive scale. An amendment to the constitution (1912) authorized the Legislature to levy a one-mill tax, the proceeds to be distributed among the counties and used for road building and maintenance; another amendment (1920) authorized the Legislature to issue bonds and provided for the taxation of motor vehicles in order to finance a system of state trunk highways covering 7,000 m. and comprising 70 routes which will reach every county seat and important community. There were in 1921 about 98,000 m. of public roads in the state.

*Education.*—The State Department of Education, as reorganized in 1919, consisted of five citizens, appointed by the governor for terms of five years. The board appoints the commissioner of education, who is actual head of the Department, and holds office for six years. In 1920 240 high schools, 261 graded schools, 255 consolidated schools, and 6,107 rural schools fulfilled the requirements of the Department of Education and therefore received, in addition to local support, state aid, derived from a one-mill tax, from the income on the permanent school fund ($30,920,032 in 1920), and from legislative appropriations. During the year 1920 $38,358,555 was expended upon public education, an average of $76.16 per pupil. A new normal school, the sixth, was opened at Bemidji in 1919. By an Act of 1921 the state normal schools were renamed state teachers' colleges and were authorized to award appropriate degrees. These colleges are controlled by a board consisting of the commissioner of education and eight members appointed by the governor for terms of four years. The university of Minnesota at Minneapolis comprises 13 colleges and schools, those most recently organized being the school of nursing (1909) and the school of business (1919). A noteworthy development in the medical school is its affiliation with the Mayo Clinic at Rochester. In 1915 William J. and Charles H. Mayo, the famous surgeons, established the Mayo Foundation for Medical Education and Research, endowed it to the amount of $1,500,000 and gave it to the university. By virtue of this gift the university controls practically all medical instruction in Minnesota and has been enabled to develop research and graduate instruction in medicine. The Department of Agriculture includes a college of forestry, a school of traction engineering, and a department of home economics. Schools of agriculture and experiment stations at Crookston, Morris, Grand Rapids, Duluth, Waseca, Cloquet, and Zumbra Heights afford assistance and instruction to farmers and students of agriculture in all parts of the state. The university library of 350,000 volumes is supplemented by a number of other libraries accessible to students. These are the Minneapolis Public Library and, in St. Paul, the state Law Library, the library and manuscript collections of the Minnesota Historical Society, housed in a new building erected by the state in the years 1916–8, and the St. Paul Public Library, which with the Hill Reference Library, established by the late James J. Hill, occupies a new and beautiful building. In 1919–20 the university had 9,027 students; in 1920–1, 930 faculty members and 231 buildings (including agricultural schools and experiment stations), erected at a cost of $6,177,443. An extensive building programme covering a period of 10 years was initiated in 1919, when the Legislature appropriated $5,600,000 for this purpose. Besides this the university's income from the state amounts to about $7,500,000 for the biennium 1921–3. Since 1911 the university has had three presidents: Dr. George E. Vincent, 1911–7; Dr. Marion L. Burton, 1917–20; and Dr. Lotus D. Coffman.

*Government.*—In 1921 the state's machinery for the supervision of labour was reorganized. An industrial commission of three members appointed by the governor superseded the single commissioner previously controlling the Department of Labour. As reorganized, the Department consists of seven divisions: workmen's compensation, boiler inspection, accident prevention, statistics, women and children, employment and mediation and arbitration. The law creating the industrial commission vests it with special powers and duties: (1) to administer the workmen's compensation law; (2) to establish and conduct free employment agencies, supervise the work of private employment agencies, and deal with the problem of unemployment; and (3) to promote voluntary arbitration in labour disputes by appointing, if desirable, temporary boards of arbitration or conciliation and by conducting investigations and hearings.

The consolidation of the direction of the state's charitable and penal institutions under the state Board of Control was completed in 1917, and the Board in 1921 had charge of 17 institutions. Two new ones are an asylum for the insane, with a special ward for inebriates at Willmar (1914), and a state reformatory for women at Shakopee (1920). The new state prison buildings at Stillwater, completed in 1912, cover 22 ac. in a tract of 1,000 ac. The most advanced methods of discipline and management are used, and prisoners are paid wages for their labour. During the year 1919 the *per capita* expense for each prisoner was $368.30 and the earnings averaged $906.66. In the fiscal year ending in June 1920, receipts from prison industries were over $5,000,000. The remarkable development of the prison was due largely to Henry Wolfer, warden from 1892 to 1914. The Legislature of 1921 increased the membership of the state Board of Control from three to five and provided that two members shall be women. The policy of establishing and maintaining state parks, of which Itasca state park was the first in 1891, has been followed consistently, with the result that there were in 1921 14 such parks, located on tracts of land selected for scenic beauty or historic interest. Those recently established are Alexander Ramsey state park in Redwood county (1911); Fort Ridgely state park, Nicollet county (1911); Horace Austin state park, Mower county (1913); Jay Cooke state park, Carlton county (1915); Sibley state park, Kandiyohi county (1919); Toqua Lakes state park, Big Stone county (1919); Whitewater state park, Winona county (1919); Scenic state park, Itasca county (1921); and Sleepy Eye Lake state park, Brown county (1921). In addition the state maintains the Pillsbury state forest, Cass county, and the Burntside state forest, St. Louis county. Two Federal forest reserves are also located in the state: Superior National Forest in St. Louis, Lake and Cook counties; and Minnesota National Forest in Itasca, Cass and Beltrami counties. In 1913 the number of legislative districts in the state was increased from 63 to 67; and in 1920 the term of judges of probate was lengthened from two to four years by constitutional amendment. Over 60 cities of the state, including the three largest, have adopted home-rule charters under the constitutional amendment adopted in 1896 and readopted with some slight changes in 1898. Minneapolis, after many unsuccessful attempts, finally voted favourably on a home-rule charter in 1920.

*Finance.*—On June 30 1920 there were 1,584 banking institutions in Minnesota, of which 1,151 were state banks, 24 trust companies, 9 savings banks, 69 building and loan associations, and 331 national banks. Their deposits amounted to about $800,000,000. The Federal Reserve Bank for the ninth district is located in Minneapolis. All banking institutions other than national banks are under the supervision of the superintendent of banks. This official, or his deputies, according to the Act of 1909 which created the Department of Banking, examines at least twice a year the banks and other moneyed corporations created under state laws. In 1918, $15,262,760 in income taxes was paid by 84,515 Minnesotans on total net incomes amounting to $291,074,629. The total value of taxable property in the state was $2,084,000,000 in 1921 as compared with $1,194,962,312 in 1910.

*History.*—The most important political movement of recent years was the growth of the Non-partizan League. The League, organized in North Dakota in 1915 by Arthur C Townley, aimed to secure "state ownership of elevators, flour-mills, packing-houses and cold-storage plants, the central equipment concerned with the marketing of the farmers' products." The League's organizers began to work in Minnesota in 1916, and in Jan. 1917 its national headquarters were established in St. Paul. To enlist support from the urban population the League attempted to ally itself with labour, through the organization of a Working People's Non-partizan Political League. In June 1920 this movement nearly captured the Republican primary in spite of the fact that the regular Republicans held a pre-primary convention to choose one candidate on whom they should concentrate their votes. Organized labour has rapidly increased its membership, the figures of July 1920 indicating 717 labour unions with a membership of over 90,000. The members of over 80% of the unions reporting to the state Department of Labour received wage increases during the biennium 1918–20. In the same period the Department received reports on 74 strikes, involving 51,940 persons.

Probably the two most important pieces of legislation in the decade 1910–20 were the primary law and the so-called tonnage tax. The former, passed in 1912, provides that candidates for state and county offices be nominated at primary elections in June preceding the general election. With the exception of the state executive officers, the railway and warehouse commissioners, and the clerk of the Supreme Court, all state and local officers, including members

of the Legislature, are nominated, and consequently elected, on a non-partizan ballot. The 1921 Legislature provided for pre-primary conventions, but all attempts to modify the non-partizan features of the law have failed. The same Legislature passed an Act for a 6% tax on the net value of mined iron ore, tonnage tax bills having previously been vetoed by Governors Johnson and Burnquist. The alignment on the question was largely sectional, legislators from the mining districts opposing. In Oct. 1918 occurred the most severe forest fires that the state ever knew. The fires burned over 770,500 ac., principally in Aitkin, Pine, Carlton, and St. Louis counties, caused 432 deaths, destroyed about $25,000,000 worth of property, wiped out the thriving towns of Moose Lake and Cloquet, and threatened Duluth. Since this disaster the state forestry board (created in 1911) has greatly increased the state force of forest patrolmen, and during the season of danger local authorities supplement this force. During the unusually dry autumn of 1920, 860 fires were reported (as compared with 525 in 1918), but these were so promptly extinguished that less than 100,000 ac. were burned over.

The following governors held office after 1909: Albert Olson Eberhart (Rep.), 1909–15; Winfield Scott Hammond (Dem.) (died in office), Jan.–Dec. 1915; Joseph A. A. Burnquist (Rep.), 1915–21; Jacob A. O. Preus (Rep.), 1921– .

During the World War the Minnesota National Guard, after serving on the Mexican border in 1916–7, was incorporated in the army, and a total of 123,325 Minnesota men by enlistment and draft entered various arms of the service. The 151st U.S. Field Artillery and Base Hospital No. 26 were probably the most distinctively Minnesotan units in the service. War training schools in Minnesota included the reserve officers' training camps at Fort Snelling, the U.S. Air Service Mechanics' School in St. Paul, the Dunwoody Naval Training Station in Minneapolis, and the Students' Army Training Corps, organized at the state university and at numerous smaller colleges and schools. In order that "Minnesota might have, during the period of the war, a governing body capable of efficiently mobilizing its resources in men and property, and applying them to the war's successful prosecution," the Legislature in April 1917 created the Minnesota Commission of Public Safety, the first of such commissions in the United States, and appropriated $1,000,000 for its use. The people of Minnesota purchased $483,642,950 worth of Liberty Bonds and war savings stamps and contributed about $10,000,000 to war relief agencies. (S. J. B.)

**MINTO, GILBERT JOHN ELLIOTT-MURRAY-KYNYNMOND,** 4TH EARL OF (1845–1914), English statesman (*see* 18.564), died at Minto House, Hawick, March 1 1914.

**MIŠIĆ, ŽIVOJIN** (1855–1921), Serbian statesman, was the son of well-to-do peasant parents in a village under Mt. Suvo Bor, in the heart of the famous Shumaja (Shumadia) district, which had always been the backbone of Serbian resistance alike to the Turk and to the Austrian. Born in 1855, he passed through the old Artillery school in Belgrade and served in the Serbo-Turkish War of 1877 and the short Serbo-Bulgarian War of 1885. He then devoted himself to an intense study of military history and strategy. During the Bosnian annexation crisis he became assistant chief-of-staff to Gen. Putnik, and in this capacity made his name in the first Balkan War, being promoted general. In the second Balkan War in 1913 he was mainly responsible, under Putnik's orders, for the decisive operations on the Bregalnitsa, which ended in the overthrow of Bulgaria. When the World War broke out he was once more Voivode Putnik's trusted right-hand man; and when the Austrians, after their initial failure on the Drina and Sava, invaded Serbia with stronger forces in Nov. 1914, Mišić was appointed to the command of the I. Army, which had to bear the brunt of the attack, and strongly urged a counter-offensive. Mišić's simple and unaffected heroism inspired his soldiers with confidence: his army order of Dec. 3 is worthy to rank beside Lord Kitchener's appeal to the new armies of Britain, and certainly holds a record of soldierly directness. "Trust in God and forward, heroes," was all its length. Mišić's spirit spread from his own immediate command to the whole Serbian army and found expression in the decisive victory of Rudnik early in December. The Austrians under Potiorek were driven headlong out of Serbia, with a loss of 40,000 prisoners and an enormous booty, and 10 months were to pass before an enemy was seen again on Serbian soil. Thus strangely enough was fulfilled an authentic peasant prophecy which foretold that a peasant soldier from the Shumaja would rout a northern invader within sight of his native village.

Mišić, who had been created voivode after Rudnik, distinguished himself still further during the terrible retreat of the Serbian army in the winter of 1915, before the joint German, Austro-Hungarian and Bulgarian advance. Unhappily, politics entered into the military rearrangements which followed the concentration of the wrecked Serbian army at Corfu: but Mišić stood beyond the reach even of party intrigue. After a long interval spent at a western health resort in recovering from the strain of the campaign, he resumed command of the I. Army on the Salonika front in Aug. 1917, and in June 1918 was made chief-of-staff. In this position he played a preëminent part in elaborating the plan to which the piercing of the Bulgarian front and, indirectly, the collapse of Austria-Hungary was due. As a convinced believer in Serbia's national destiny and the idea of Yugoslav unity, he did all in his power to promote the efforts of the exiled Yugoslav committee to organize Yugoslav legions on every front. His death on Jan. 20 1921, after a long and painful illness, was received with national mourning.

**MISSISSIPPI** (*see* 18.599).—The pop. in 1920 was 1,790,618, a decrease of 6,496, or 0·4%, from the 1,797,114 of 1910, as against an increase of 15·8% in the preceding decade. The negro pop. was 853,962, or 52·2% of the total as compared with 1,009,487, or 56·2% of the total in 1910. The foreign-born whites in 1920 numbered 8,019, or 0·4% of the total pop. The density was 38·6 per sq.m., as against 38·8 in 1910. The urban pop. (in places of over 2,500) was 13·4%; in 1910, 11·5%. The six cities having in 1920 a pop. of over 12,000 were:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Meridian | 23,399 | 23,285 | 0·5 |
| Jackson | 22,817 | 21,262 | 7·3 |
| Vicksburg | 18,072 | 20,814 | −13·2 |
| Hattiesburg | 13,270 | 11,733 | 13·1 |
| Laurel | 13,037 | 8,465 | 54·0 |
| Natchez | 12,608 | 11,791 | 6·9 |

*Agriculture.*—In 1920 61·3% of the land area of the state was in farms, and 51·2% of the farm land was improved. The number of farms was 272,101, a decrease of 0·8% since 1910. These farms contained 18,196,979 ac., of which 9,325,677 ac. were improved land. The improved acreage increased 3·5% from 1910 to 1920. Of the total number of farms in 1920, 91,400, or 33·5%, were worked by owners, or part-owners (68,131 by whites and 23,179 by negroes). The number of white owners increased 12·4% from 1900 to 1920 and the number of negro owners 11%. The average size of the farms decreased from 67·6 ac. in 1910 to 66·9 ac. in 1920. The average value increased from $13.69 per ac. in 1910 to $35.27 in 1920. Cotton continues the most important crop. The acreage of cotton decreased from 3,220,000 in 1907 to 3,100,000 in 1920. The number of acres planted in market-garden produce, peanuts, potatoes, sorghum-cane and corn is increasing. The live-stock industry, pure-bred hogs and cattle, made the greatest relative advance of any branch of agriculture from 1910 to 1920.

*Manufactures.*—The value of the total output from factories increased from $57,451,445 in 1905 to $79,550,095 in 1914. Mississippi ranked 39th among the states in the value of manufactured products and 31st in number of wage-earners. The capital invested in manufactures increased from $50,256,309 in 1904 to $81,005,484 in 1914, or 62%. The chief manufactured products are lumber, cotton-seed oil and cake, cotton goods (thread, drills, sheetings, muslins, etc.), turpentine and rosin. The leading manufacturing centres are: Meridian, Jackson, Greenville, Columbus, Laurel, Hattiesburg, Natchez and Vicksburg.

*Education and Charities.*—The most important development in education has been the establishment of county agricultural high schools (1908). Every county may establish one for white children and one for negroes, or two counties may combine and create one set of schools for the two counties. These schools receive state aid on the basis of the number of boarding pupils. They receive also Federal aid. To equalize the term in the grade schools between the delta and hill counties the distribution of the state school fund is based on the number of educable children in each county (1920). A compulsory school attendance law passed in 1920 applies to all children between the ages of seven and fourteen. The state has a normal college for the training of teachers, at Hattiesburg (established 1910). A five-million-dollar bond issue was authorized (1920) to provide buildings for the state's charitable institutions and institutions of higher learning. Greek letter and similar secret fraternities

are forbidden by law (1912) in all schools supported in whole or in part by the state. An industrial training school for delinquent and abandoned children is at Columbia (1916), and a tuberculosis sanatorium at Magee (1916).

*Administration and Legislation.*—In the decade 1910–20 Mississippi enacted much constructive legislation, covering a wide range. The constitution of 1890, enacted to ensure white supremacy, and still in force, has been amended with the view of putting the Government more in the direct control of the people. The initiative and referendum were embodied in the constitution by amendment (1916). An initiative petition must be supported by 7,500 qualified electors, and to refer a law to the people requires 6,000. Any "law, bill, resolution, constitutional amendment, or any other legislative measure" is a proper subject for such petitions. The state also has the recall, but does not apply it to all executive offices. The judiciary is entirely elective—circuit and chancery judges since 1912, Supreme Court judges since 1916. By a constitutional amendment (1916) the Supreme Court consists of six judges and is permitted to sit in two divisions for the consideration of cases. The term of Supreme Court judges is eight years; that of circuit and chancery judges four years. Nine or more jurors may return a verdict in all civil cases in the circuit and chancery courts (1916). The Legislature is elected for four years and meets in regular session biennially (1910). Extra sessions may be called by the governor. All appropriations are made for two years. The fee system for the pay of county officials was abandoned in 1920 and salaries paid according to the assessed valuation of the property of the counties. For this purpose the counties of the state are divided into five classes. The Torrens system for perfecting land titles has been in effect since 1915 and a uniform negotiable-instruments law was enacted in 1916. The state collects a tax of five mills on the dollar on all incomes over $2,500 (1912). A state department of banking was created in 1914 and a board of bank examiners of three is elected for four years. Bank deposits are guaranteed by state law (1916). A bureau of vital statistics was established in 1912, and the Board of Health has done much to reduce malaria, hook-worm and tuberculosis.

The state has a comprehensive child labour law, passed in 1912. No child under 12 may be employed in any mill or factory; and no child under 16 may be employed for more than eight hours per day. No employee is permitted to work in any mill or factory more than 10 hours per day. The county health officer, working under the state factory inspector, is responsible for the enforcement of the law. A pardon board of five members, appointed by the governor for four years, passes on all petitions for pardons (1916). Petitions must be published for 30 days in the county where the crime was committed. The board acts only in an advisory capacity to the governor. A state highway commission was created in 1916.

Mississippi during the World War supplied to the U.S. army 43,362 drafted men (of whom 19,296 were whites and 24,066 negroes), as well as 9,044 volunteers. To the navy 4,069 men were supplied, and to the marine corps 265.

In 1921 the state was represented in the U.S. Senate by John Sharpe Williams and Pat Harrison. The latter defeated James K. Vardaman in 1918 in a hotly contested election, turning largely on Vardaman's opposition to President Wilson's war policies. The following have been governors since 1910: Edmund F. Noel (Dem.), 1908–12; Earl Leroy Brewer (Dem.), 1912–6; Theodore G. Bilbo (Dem.), 1916–20; Lee M. Russell (Dem.), 1920– . (W. C. M.*)

**MISSOURI** (*see* 18.607).—During the decade 1910–20 Missouri continued her transition from the period of frontier influences, of rapid growth of population and development of natural resources to the stage of industrial development and growth of urban population. The transition was, however, hardly more than well begun, and the state was still primarily agricultural. The total pop. in 1920 was 3,404,055, as compared with 3,293,335 in 1910, an increase of 110,720, or 3·4 per cent. The percentage of urban pop. (in centres of 2,500 or more) increased from 42·5% in 1910 to 46·6% in 1920. Of this urban pop. 34·5% in 1920 was in the three cities of St. Louis, Kansas City and St. Joseph. The rural pop. showed an absolute decrease in both 1910 and 1920; in the latter year only 19 counties showed an increase. The pop. of the 10 chief cities was as follows:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| St. Louis | 772,897 | 687,029 | 12·5 |
| Kansas City | 324,410 | 248,381 | 30·6 |
| St. Joseph | 77,939 | 77,403 | 0·7 |
| Springfield | 39,631 | 35,201 | 12·6 |
| Joplin | 29,902 | 32,073 | −6·8 |
| Sedalia | 21,144 | 17,822 | 18·6 |
| Hannibal | 19,306 | 18,341 | 5·2 |
| Jefferson City | 14,490 | 11,850 | 21·6 |
| Moberly | 12,808 | 10,923 | 17·3 |
| Independence | 11,686 | 9,859 | 18·5 |

The Roman Catholic Church remained the largest in the state, having in 1916 445,352 members or 32·5% of the total of 1,370,551 for all denominations. There were 252,107 Baptists, 228,135 Methodists, 145,403 Disciples of Christ, 67,628 Presbyterians, 45,313 Lutherans, and 37,374 members of the German Evangelical Synod of N. America.

*Agriculture.*—In 1920, 34,774,679 ac., or 79% of the total area of the state, was in farm lands; of this 24,832,966 ac., or 71·4%, was improved. The average size of a farm was 132·2 acres. The percentage of farms operated by owners increased during 1910–20 from 69·4% to 70·4%. In 1920, 51% of the farms operated by owners were mortgaged. The increase in values of farm property in the decade, 74·9%, to $3,591,068,085, reflected primarily the general rise in price level. This rise in price level makes acreage the only intelligible basis for crop comparisons. In 1919 cereal, and hay and forage crops continued to lead. Tobacco remained a relatively unimportant crop, though widely grown, with 4,490 ac. in 1919. Cotton gained from 96,527 ac. in 1909 to 110,927 ac. in 1919. Fruit, primarily apples, continued an important crop. After 1909, the acreage in Indian corn decreased 21·7% to 5,567,079 ac. in 1919, while wheat increased 126·3% to 4,564,990 acres. The greater part of these changes occurred after 1914, resulting from the World War. The total value of all farm crops in 1919 was $559,947,856, of which the cereals contributed $394,195,226, hay and forage $95,897,050. Indian corn was valued at $219,513,084, wheat at $140,202,501, and oats at $32,394,961. Increasing progress is ensured by the extensive drainage operations in the local drainage districts of the S.E., and by the increased interests in improved farming methods and in coöperative organizations. The Agricultural College of the state university in coöperation with the Federal Government has been very active in agricultural extension work; in May 1921 65 counties had farm bureaus, 62 of which employed county farm advisers. On Jan. 1 1920 there were on the farms 906,220 horses, 389,945 mules, 1,714,894 beef cattle, 1,966,750 dairy cattle, 1,271,616 sheep and 3,888,677 swine. The total value of these animals was estimated at $361,841,529. There were 24,883,985 chickens, an increase of 25% over April 15 1910. In 1919 Missouri produced 7,705,993 lb. of wool; dairy products were valued at $34,752,845, and eggs at $42,193,285.

*Mines and Quarries.*—Lead and zinc continued to be by far the most important mineral products, with a total value of $51,747,580 in 1917, about two-thirds of it for lead, and $27,462,050 in 1918, four-fifths for lead. Under the stimulus of the World War the amount mined as well as the values showed a marked increase; in 1910 Missouri ore produced 161,659 short tons of lead; in 1916 347,869 tons; in 1917 218,253 short tons; and in 1918 287,983 tons. Zinc ore increased from 256,667 short tons in 1910 to 304,070 in 1916, more than one-fourth of the national total, but fell to 113,371 in 1918. Iron, copper, nickel and cobalt, though relatively less important, showed marked increases in 1916, 1917 and 1918, and Missouri retained first place in the production of barytes. The value of coal mined in 1918 was $17,126,498; building stone (chiefly limestone) was valued at $1,652,389. The total value of mining and quarry products was $67,674,146 in 1918; the value of clay products was $9,198,184 and of cement $7,132,470.

*Manufactures.*—From 1909 to 1914 the total value of manufactured goods increased 11·1% to $637,952,128, while the added value increased 13·4% to $249,237,269. The total of capital invested was $522,548,083. Twelve industries in 1914 had a product valued at more than $10,000,000 each and as a group produced 60·5% of the total value and employed 55·1% of the total wage-earners. Slaughtering and meat-packing continued to furnish the largest single item—$92,060,499 or 14·4% of the total; the boot and shoe industry was second with $52,522,006 (8·2%); flour and grist mills third with $38,686,309 (6·1%); and tobacco fourth with a product valued at $33,380,843 (5·2%). Other industries were malt liquors ($31,801,404); lumber and timber ($18,396,838); men's clothing ($17,300,109), and cars and general shop construction and repairs by steam railways ($12,847,319). The two cities of over 100,000, St. Louis and Kansas City, gave employment to about two-thirds of the wage-earners and produced two-thirds of the total values, St. Louis contributing over half the total in both items.

*Government.*[1]—Fifty-five constitutional amendments were submitted to popular vote between 1910 and 1920. From 1910 to 1918 out of 42 only one, permitting the pensioning of the blind, was adopted. The bitter opposition to State prohibition (defeated in 1910, 1916 and 1918) and to the single tax (rejected in 1912 and 1918) contributed to the popular distrust of all amendments. In 1920, however, 9 out of the 13 proposed were adopted. Nearly half of all the amendments proposed to relax the limitations on taxing or borrowing power. Seven (all rejected) were to provide more revenue for education, eight (two adopted in 1920) for good roads, and six (two adopted in 1920) relaxed the debt limits for the local units. Other rejected amendments of general interest were those proposing woman suffrage by State action (1914); a State tax commission

[1] The legislation of 1921 is subject to rejection through the referendum.

(1912); rural credit schemes (1916, 1918); increased pay for legislators (1910, 1914, 1920); pensions for police and school teachers in cities (1910). The uniform failure, until 1920, of the proposed amendments stimulated a demand for a new constitution. Although endorsed by both parties since 1916, the proposal was not submitted by the Assembly, largely because of partizan opposition to the basis of representation in the convention. A constitutional amendment, proposed by the initiative, was adopted by popular vote in 1920, including a compromise on apportionment, and providing that the question of holding a constitutional convention should be submitted to the voters at least every 20 years and for such a submission at a special election in 1921. Missouri ratified the Sixteenth Amendment to the Federal Constitution (income tax) in 1909, the Seventeenth (direct election of U.S. Senators) in 1911, the Eighteenth (prohibition) and Nineteenth (woman suffrage) in 1919. An Amendment to the constitution of the state adopted in 1920 gave cities of over 100,000 the right to draw up their own charters. Fifteen of the proposed constitutional amendments were submitted through the initiative, including prohibition (twice), the single tax (twice) and woman suffrage. Only one of the 15 was adopted, that providing for a new method of summoning a Constitutional Convention (1920). Six Acts of the Legislature have been submitted to a popular vote through the referendum; four were rejected in 1914, including the minimum train crew Act. The "bone dry" prohibition Act was upheld in 1920, but workmen's compensation was defeated.

The more important new administrative boards and bureaus were the Food and Drug Commissioner, 1909 (abolished 1921); the Public Service Commission, 1913; the State Highway Department, 1917; and the Tax Commission, 1917 (abolished 1921). The Public Service Commission 1913 with real powers of regulation marked a departure from the earlier Missouri practice of leaving the regulation of public utilities to local city boards. Consolidation of departments and commissions, urged by Gov. Hadley, began in 1917, when the penitentiary and other reformatory institutions were placed under a single prison board, and by 1921 had made substantial progress. Seven general departments were created: the Department of Finance, including the old Departments of Banking, Building and Loan Associations and Soldiers' Settlement; Commissioner of Public Welfare, including various departments in charge of inspections; the Board of Eleemosynary Institutions; Department of Labour; Department of Agriculture; and the Department of Budget, to take over the supervisory and budget-recommending powers of the Tax Commission and serve also as a purchasing department.

Missouri remained conservative in labour legislation; a minimum train crew law was defeated in 1914, and a workmen's compensation law in 1920, both by the referendum. A new compensation law, elective on the part of the employer, was passed in 1921. A fairly comprehensive but very moderate Act was passed in 1913 to provide for the health and safety of employees, including limitation of hours for women. The compulsory school attendance law of 1919 incidentally limited child labour. The greater part of a children's code, recommended by two commissions, was put in the statute book.

*Revenue.*—The revenue, inelastic through constitutional limitations, proved increasingly inadequate after 1910, until the unpaid current obligations in 1917 totalled $1,800,000, in spite of many vetoes of appropriations. Attempts to secure relief for special purposes such as schools and good roads by constitutional amendments had all failed. The Assembly in 1917 passed new indirect taxes, a state income tax, a corporation franchise tax, a direct inheritance tax (superseding the collateral inheritance tax), a secured debts tax, "soft" drinks stamps and wholesale liquor dealers' licence, which yielded altogether nearly $2,400,000 in 1917–9. It also established the Tax Commission which in 1918 and 1919 urged a 100% assessment for the direct property tax to secure uniformity of taxation and increase of revenue. The state Board of Equalization raised the total assessed valuation about 20% in 1919 and proposed a further substantial increase in 1921. The assessed valuation of real and personal property increased from $1,658,587,414 in 1916 to $2,471,746,046 in 1920. The total revenue of the state was $7,151,125 in 1910 and $17,666,137 in 1918. The *per capita* cost of state government was still low, $4.51 in 1919; the direct property tax levy was only $0.54 on the $1,000 of actual cash value in 1916, and $0.88 in 1919. The outstanding state debt Jan. 1 1921 consisted of $4,398,839 certificates of indebtedness in the school and seminary funds, and $1,500,000 capital refunding bonds, a total of $5,898,839. The net indebtedness of the counties in 1913 was $6,580,450 and of incorporated places $46,999,383.

*Charitable and Penal Institutions.*—An industrial home for negro girls was authorized in 1909 and opened at Tipton in 1916. The Training School for Boys at Boonville was in 1915 transformed into the Reformatory for Boys. In 1917 the administration of the penitentiary was reorganized, contract convict labour abolished and conditions improved.

*Education.*—Missouri appropriates one-third of the general revenue to the support of the public schools, amounting to $1,618,341 in 1910 and to $3,423,849 in 1920. To this must be added $187,040, the interest on the state's common school fund of $3,159,000. The estimated total expenditure for public schools from state and local sources rose in the decade 1910–20 from $13,905,188 to $28,048,051. The permanent county and municipal funds of the counties, derived from the proceeds of the sales of stray animals and from escheats and fines, and from permanent township funds, derived from the sale of lands granted by the Federal Government, increased from $9,825,991 to $11,561,583. The average daily attendance of the public schools rose from 490,374 to 531,221. Although the public schools continued to lack sufficient revenue, there was much constructive legislation, especially as to the rural schools. The state funds were apportioned on the basis of the number of teachers and attendance instead of enrolment (1911) and additional aid was given to rural schools (1909, 1911, 1915) and to high schools (1913) in the poorer districts. The size of the local school district for purposes of administration and taxation was increased through authorizing the appointment of county superintendents (1909), encouraging the consolidation of schools (1913, 1917) and especially by the county unit Act of 1921, which, in all counties that do not include a first-class high school, made the county the unit for administration and taxation. The requirements for teachers' certificates were raised in 1911 and 1921 and provision made for the training of teachers in the high school (1913). An effective compulsory attendance law was passed in 1919. Under the Federal Smith-Hughes Act, Missouri received in 1920 $103,808 from the Federal Government for vocational education and for the training of teachers. The enrolment in the state university at Columbia and Rolla increased from 3,083 (165 at the School of Mines at Rolla) in 1911 to 5,800 (466 at Rolla) in 1920. For the biennial period 1911–2 the university received from interest on the state Seminary Fund, state appropriations, income on endowment, and from the Federal Government a total of $1,555,712; for the biennium 1919–20, the corresponding total was $2,483,808. The Extension Division was organized in 1913; the School of Commerce in 1914, expanded in 1916 to the School of Commerce and Business Administration. There was notable development in extension work in agriculture and home economics under the recent Federal aid laws. In 1911 the university was placed on the approved list of the Carnegie Foundation for the Advancement of Teaching.

*History.*—Governor Hadley was a leading supporter of Roosevelt for the Republican nomination in 1912, though supporting Taft in the election. Wilson that year received 330,746 votes, Taft 207,821, Roosevelt 124,371. In 1916 Wilson defeated Hughes by 28,693, but the Democratic candidate for governor defeated the Republican by only 2,263. In 1918, however, Folk, the Democratic candidate for U.S. Senator, ran 35,283 behind Spencer, Republican, while the Republican candidate for state Superintendent of Education won over the Democratic by 1,109. The disorganization in the local Democratic party was increased by the opposition of Senator Reed to the League of Nations and, with the general national reaction, resulted in 1920 in the election of a Republican state administration and a Republican majority in both Houses of the Assembly (for the first time since 1870) and in a presidential majority for Harding over Cox of 152,363.

In the World War Missouri furnished (to Oct. 31 1918) 140,257 men; of these 92,843 were inducted under the Selective Service Act. Her losses were 1,270 killed in action; 1,531 dead from wounds, disease and accident; a total of 2,801. Missouri's subscription and quota for the First Liberty Loan were respectively $51,863,388 and $65,562,800; for the Second $80,810,400 and $122,226,600; for the Third $79,599,700 and $110,828,300; for the Fourth $163,884,700 and $172,832,700; and for the Fifth, or Victory Loan $119,118,050 and $121,627,550. Missouri was one of the first states to establish (April 24 1917) a State Council of Defense which, through a very efficient system of county councils, greatly increased the production of food-stuffs, increasing the wheat acreage over 20% in 1917, and by an even greater percentage in 1918, and investigated the few cases there were of disloyalty or disaffection.

Recent governors have been Herbert S. Hadley (Rep.), 1909–13; Eliot W. Major (Dem.), 1913–7; Frederic D. Gardner (Dem.), 1917–21; Arthur M. Hyde (Rep.), 1921– . (J. VI.)

**MISTRAL, FRÉDÉRIC** (1830–1914), Provençal poet (*see* 18.616), in 1906 published a Provençal translation of *Genesis*, and *Olivades*, a collection of Provençal poems, in 1912. His memoirs appeared, under the title *Mes Origines*, in 1906. He died at Maillarre, near Marseilles, March 26 1914.

See P. Brousse, *Frédéric Mistral* (1903); E. Lefèvre, *Bibliographie mistralienne* (1903); H. J. Bocken, *Frédéric Mistral* (1910); J. Brochet, *Frédéric Mistral* (1910); J. Charles Roux, *Le Jubilé de Fr. Mistral* (1912); E. Ripert, *La Versification de Frédéric Mistral* (1917); P. Lasserre, *Frédéric Mistral* (1918); J. Vincent, *Frédéric Mistral: sa vie et son influence* (1918).

**MITCHELL, SILAS WEIR** (1830–1914), American physician and author (*see* 18.618), died in Philadelphia, Pa., Jan. 4 1914. After 1910 he published *John Sherwood, Ironmaster* (1911), *Westways* (1913), and *Complete Poems* (1914).

**MOHN, HENRIK** (1835–1916), Norwegian meteorologist, was born at Bergen May 15 1835, his family being of German origin. He was educated at the Cathedral school, Bergen, and afterwards entered the university of Christiania, where he took his doctor's degree in 1852. In 1861 he became an observer at the Christiania observatory, in 1866 was elected professor of meteorology at Christiania University, and in 1866 was appointed director of the Norwegian Meteorological Institute, which he was largely instrumental in founding. He retained this post until 1913. Mohn's meteorological researches were of the highest importance. His *Études sur les mouvements de l'atmosphère*, written in collaboration with the mathematician Goldberg (1876–8), is a work of great value for the study of the dynamics of the atmosphere, and the authors continued their researches on the subject in various papers contributed to the *Zeitschrift der Oest. Meteor. Gesell.* (1877–8). Mohn did much work on the subject of storms, publishing storm maps of the Atlantic (1870–1), and he also carried out researches (1876–8) on the meteorology and oceanography of the northern Atlantic. He worked out and published the meteorological observations of various polar expeditions, including those of Nansen in the "Fram" (1893–6), the second "Fram" expedition (1898–1902), and Amundsen's south polar journey (1910–2), some of his papers appearing as supplements to *Petermann's Mitteilungen*. He also published many articles on the climate of Norway and conducted investigations into the use of the hypsometer, which are of great importance for the study of the physics of the earth. Besides the works mentioned above, he produced *Grundzüge der Meteorologie*, which has gone through numerous enlarged editions since its first appearance in 1872 as a small text-book. Mohn was a member of many foreign scientific societies, and was senior hon. member of the Royal Meteorological Society of London, having been elected in 1874. He died at Christiania Sept. 12 1916.

**MOLESWORTH, MARY LOUISA** (1839–1921), Scottish writer (*see* 18.660), died in London, July 21 1921.

**MOLTKE, HELMUTH VON** (1848–1916), Prussian general, chief of the German general staff at the outbreak of the World War, was born at Gersdorf in Mecklenburg on May 23 1848, and was the nephew of the great Moltke. From 1902 to 1904 he was in command of the 1st Div. of the Guards Corps with the rank of lieutenant-general. In 1906 he was appointed chief of the general staff of the army. He was responsible for the general conduct of the German operations at the beginning of the World War and is now known to have been acting upon the plan for the invasion of the north-east of France and a rapid advance upon Paris which had been drawn up by his great predecessor, Gen. von Schlieffen. In important particulars, however, he appears to have deviated from Schlieffen's plan, and in particular to have failed to concentrate sufficient force in the blow which was delivered on the north-east. He has likewise been charged with having failed to coördinate the positions of the German forces on the eve of the battle of the Marne, and having allowed to be issued confusing orders which contributed to the German defeat in that decisive battle. About the same time his health had become seriously impaired, and on Oct. 25 1914 he was relieved of his post and was succeeded by Gen. von Falkenhayn. He was entrusted in Berlin with the office of chief of the home substitute for the general staff (*Der stellvertretende Generalstab*), which had the task of organizing and forwarding the reserves and of controlling the Territorial army corps, corresponding to those at the front. General von Moltke died suddenly at a celebration in the Reichstag building on June 18 1916. He left memoirs entitled *Die "Schuld" am Kriege*, which up to 1921 had not yet been published.

**MOND, SIR ALFRED MORITZ, 1ST BART.** (1868– ), British politician, was born at Farnworth, near Widnes, Lancs., Oct. 23 1868, the son of the famous chemist Ludwig Mond (*see* 18.693). He was educated at Cheltenham and St. John's College, Cambridge, and afterwards at Edinburgh University. In 1894 he was called to the bar, and afterwards joined the North Wales and Chester circuit. He entered the firm of Brunner, Mond & Co., becoming a director in 1895, and also became chairman of the Mond Nickel Co. and a director of the South Staffordshire Mond Gas Co. and various other companies. He was elected to Parliament in 1906 as Liberal member for Chester, losing his seat in 1910, but the same year was elected for Swansea and created a baronet. On the formation of Mr. Lloyd George's Ministry in 1916 he became First Commissioner of Works, and in 1921 he became Minister of Health. Sir Alfred Mond was in 1908 chairman of the chemical industries section of the Franco-British exhibition. He published many articles on the alkali trade in scientific and economic journals, besides a volume of essays, *Questions of To-day and To-morrow* (1912). His wife Violet, daughter of J. H. Goetze, was well known in society, and was created D.B.E. for her work during the war; and their daughter Eva Violet married in 1914 Visct. Erleigh, eldest son of Lord Reading.

**MONET, CLAUDE** (1840– ), French painter (*see* 18.694). In his later years Monet worked at his painting solely in the neighbourhood of Giverny, where he lived, and devoted himself to the study of modifications in the aspect of a limited number of subjects caused by changes in the light and the seasons. On the motive of the "Bassin aux Nymphéas" he produced a series of twelve large compositions. Another series, painted in 1913, is the "Arceaux Fleuris," which represents a corner of his garden at Giverny. In 1918 he produced a number of similar studies under the general title of "Saule Pleureur."

**MONEY MARKET** (*see* 17.732*).—Like most of the terms current in business or in economics, the phrase "money market" is used in different senses. It sometimes means the whole financial machinery as applied to the creation, collection and distribution of both credit and capital, and so includes not only the banks, accepting houses and discount houses, but also the stock exchange, bullion brokers, dealers in foreign exchange, company promoters, and all others who handle the business of lending and investing money and transferring it from one country to another. The subject of the present article, however, is the money market in the narrower sense of the phrase, covering the machinery of the creation and distribution of credit—that is to say, of banking money which can be produced for the use of borrowers by banks and financial firms and companies. Loan issuers, company promoters, and stockbrokers do not exercise this power of creating money; they collect money saved by the public or borrowed by the public from bankers, and hand it over to governments, municipalities or industrial and commercial users to be used by official borrowers for public works, or for military expenditure, or to cover a deficit, and by industry and trade in developing production and distribution. The money market, however, in its strict and narrower sense not only collects money but creates and expands its supply. In England, where before the World War the money market had been developed to a very high point of elasticity and specialization, it worked by means of a ring of banks grouped round the Bank of England as its centre, with the assistance of accepting houses, a group of private firms of high standing, who performed an important function in the creation of bills of exchange, and the discount houses or bill-brokers, a group of joint-stock companies and private firms, which specialized in buying and selling bills of exchange, using for this purpose money largely borrowed from the banks.

In any country which founds its monetary system on a scientific basis the power of the banks to create credit cannot be expanded indefinitely; some check must be imposed either by law, or, as in England, by convention, tradition and the prudence of the bankers. Caution on their part is stimulated by the fact that they have always to be ready to meet demands upon them in legal-tender cash; and so the amount of credit which they can prudently create is limited by the amount of legal-tender cash that they have available or can obtain if required.

Legal-tender cash means cash that can be legally tendered, and must be received by the creditor, in payment of a debt. In

England it consisted before the war of gold sovereigns and half-sovereigns and Bank of England notes, which could be tendered up to any amount; silver coins, which could be tendered for payments of not more than forty shillings; and bronze coins up to 12 pence. Since, as will be seen, the amount of Bank of England notes that could be issued depended strictly upon the amount of gold held by the Bank, it thus followed that the amount of gold at the Bank of England and in the hands of the other banks limited the amount of banking currency which the banks were able to create, owing to the fact that this banking currency was convertible on demand into legal-tender cash. This was the justification for the statement that the basis of British credit was gold; but it should be remembered that this statement only conveys half the facts of credit creation. Gold was the basis of credit in so far as it limited the amount which the bankers could prudently make themselves liable to provide if called upon; but another and very important part of the basis of credit consisted of the wealth and standing of the borrowers and the security which they were able to offer for the repayment of the loans, advances and discounts through the creation of which new credit was produced and new banking money was put into circulation.

Returning now to the group, described above, that conducted credit operations in the City of London before the war, we find at the centre of it the Bank of England, whose strength and prestige depended on the fact that it was banker to the British Government and so was believed to be able always to rely upon its support in time of crisis, and also to the great joint-stock banks which had covered England with their branches and held, as we shall see, a balance at the Bank of England as part of their cash reserve, another very important item in which was their holding of Bank of England notes. The issue of these notes was strictly regulated by the terms of the Bank Act of 1844. Up to £18,450,000 (originally £14,000,000) notes could be issued against securities; beyond this sum every note had to be backed by its equivalent in coin and bullion; according to the terms of the Act, one-fifth of this bullion might consist of silver, but this power had never been exercised since 1861; after that date the metallic backing of the Bank of England's note issue always consisted of gold. The securities held against the £18,450,000 notes—the fiduciary issue as they are usually called, which have no metallic backing—have always been Government securities, but this restriction is not imposed by the Bank Act, which only instructed the Bank to transfer to its issue department securities, of which the public debt of 11 millions (a book debt from the Government to the Bank) should form part.

No such legal restrictions limited the extent to which the Bank of England and the other banks of the country could create credit for their customers. In its issue department, which conducts the note issue, the Bank of England was tied hand-and-foot by the Act of 1844. In its banking department it was free to create credit to any extent that its own prudence permitted, and it is this fact that gave the London monetary system the elasticity combined with control which was one of its chief claims to efficiency. The Bank could not, without breaking the law, expand its note issue without an equivalent expansion in its holding of bullion, but it could, according to its own judgment, by making advances and discounting bills, expand the amount of credit in its books held by the other banks; and these book credits at the Bank of England were regarded by the other banks and by the whole financial and commercial community as practically the equivalent of legal-tender cash at least for balance-sheet purposes. To make the matter clearer, specimens are here appended of a pre-war Bank of England return and a balance-sheet of the largest joint-stock bank.

### BANK OF ENGLAND

*Account for the Week ended Wednesday, July 15 1914*

ISSUE DEPARTMENT

| | | | |
|---|---|---|---|
| Notes Issued | £56,908,235 | Government Debt | £11,015,100 |
| | | Other Securities | 7,434,900 |
| | | Gold Coin and Bullion | 38,458,235 |
| | £56,908,235 | | £56,908,235 |

BANKING DEPARTMENT

| | | | |
|---|---|---|---|
| Proprietors' Capital | £14,553,000 | Government Securities | £11,005,126 |
| Rest | 3,431,484 | Other Securities | 33,623,288 |
| Public Deposits | 13,318,714 | Notes | 27,592,980 |
| Other Deposits | 42,485,605 | Gold and Silver Coin | 1,596,419 |
| Seven-day and other Bills | 29,010 | | |
| | £73,817,813 | | £73,817,813 |

### LONDON CITY AND MIDLAND BANK

*Balance Sheet, June 30 1914*

(Condensed and simplified)

| | | | |
|---|---|---|---|
| Paid-up Capital | £ 4,348,650 | Cash in Hand and at Bank of England | £15,128,192 |
| Reserve Fund | 3,700,000 | Money at Call and Short Notice | 12,510,356 |
| Current, Deposit and other Accounts (including Undivided Profits) | 95,027,439 | Investments | 8,835,697 |
| Acceptances | 7,353,110 | Bills of Exchange | 10,230,300 |
| | | Advances, Loans and other Accounts | 54,081,382 |
| | | Liability of Customers for Acceptances | 7,353,110 |
| | | Premises | 2,290,162 |
| | £110,429,199 | | £110,429,199 |

In an ordinary bank balance-sheet the first item on the "Assets" side consisted of: "Cash in hand and at the Bank of England," which were put together under one heading as if there were no practical difference between a holding of legal-tender cash and a credit in the books of the Bank of England. By means of this convention, cash at the Bank of England could be very easily expanded, through advances made by it which became cash at the Bank of England in the balance-sheets of the other banks, whenever there was need for an abnormal amount of money at seasons such as the end of each quarter and especially the last day of the year, owing to heavy payments then made and the large number of balance-sheets, both banking and other, which are then drawn up. These advances were seldom or never made directly to the other banks. The second line in the assets in their balance-sheets consisted of: "Money at call and short notice," which were usually made to discount houses and stock-brokers, though other borrowers, such as Indian and Colonial banks and foreign banks and financial firms, also took large sums at times from the English banks. By calling in some of this money at times of stringency the banks used to compel the discount houses to borrow from, or discount bills at, the Bank of England, and stockbrokers to borrow from it, in order to repay them: the fresh credit so produced was paid into the accounts of the banks and so increased their holding of cash at the Bank of England. This system worked with very great ease and elasticity, but was obviously liable to abuse and tempted the bankers to create credit, perhaps sometimes too freely, relying on this power to replenish their resources as described. The same result was produced when the Government found it necessary to borrow from the Bank of England at times when its expenditure was temporarily larger than its revenue. If, for example, the Government borrowed 2 millions from the Bank on "Ways and Means" or "Deficiency" Advances, in order to pay for battleships or meet the interest on Consols, the Bank of England gave them so much credit in its books, which it paid out to shipbuilders or Consols holders in the form of cheques on the Bank, and those who received this newly created money paid the cheques into their own accounts at their own banks, which thus received an addition to their cash at the Bank of England. Thus, whether the borrowing was done by the Government or by the financial community, the result was usually an addition to the other deposits in the banking department of the Bank of England, with a corresponding increase in the securities on the other side. If the Government were the borrower the increase would be under Government securities; if the borrowing was done by other customers the increase would be in "other" securities. It should be noted that the "other deposits" in the Bank of England's banking department include many other accounts besides those of the other banks. The public deposits are exclusively those of the British Government; the accounts of any

other public body, such as the Indian Government and Colonial Governments or British municipalities, and all the private customers who bank with the Bank of England, are included with the other banks in the "other deposits."

On this basis of "cash in hand and at the Bank of England" the other banks had built up the great organization which had covered England with a network of branches which collected, distributed and created cash and credit for the community. The specimen balance-sheet given above needs little explanation. On the liabilities side we have the capital subscribed by the shareholders to start the business, which is only a liability in the sense that it would have to be repaid or accounted for if the bank were wound up. The reserve fund has been accumulated out of past profits and is also a liability only in the sense that it is the property of the shareholders and has to be accounted for. A liability in a much more real sense is the item of current and deposit accounts which makes up the greater part of the total. This is money deposited by the public and liable to be withdrawn on demand in the case of current accounts, or after notice of seven days or some other short period in the case of deposit accounts. On the other side of the account we see: "Cash in hand and at the Bank of England," "Money at call or short notice," which has been lent, as already described, to discount houses, stockbrokers, and other professional dealers in money. The "Bills discounted" are bills of exchange, most of which are probably drawn on other banks or the great London accepting houses, though they also include a considerable number of local bills discounted for industrial customers. With a portfolio of bills of this kind, arranged so that a certain proportion fell due every day, a bank could always replenish its cash by refraining from buying new bills to take the place of those maturing. "Investments" are the bank's holding of British Government and other securities, usually of a kind which it would expect to be able to realize by sale on the Stock Exchange in the case of any sudden demand upon it for cash. The large item of "Loans and advances" expresses the activity of the bank in financing industry and trade by lending money to customers. Here again it should be noted that, just as the Bank of England, by lending money or discounting bills, increased the amount of its own deposits, so the other banks by the same process increased the aggregate of general banking deposits. The borrowing customer gets a credit (say for £10,000) from his bank A, against which he would draw a cheque to make the payment for the purpose for which he borrowed the money. If the cheque was paid to a customer of the same bank its deposits would be increased by £10,000 and its loans and advances by the same amount, its cash total being unaffected. If the recipient of the cheque banked with another bank, B, then the cheque would, through the machinery of the clearing-house, transfer £10,000 of cash at the Bank of England from bank A to bank B, and B's cash and the amount of its deposits will both have been increased by £10,000. Bank A would have had its cash at the Bank of England diminished by £10,000, but its loans and advances would have been increased by this amount and its deposits would be unaltered by the transaction; and as long as this loan was outstanding the increase that it had thus effected in the aggregate of banking deposits would remain. It will be noted that the item of acceptances which appears among the liabilities is exactly balanced on the assets side by "liability of customers on account of acceptances." This item arises out of the creation of bills of exchange which had been accepted by the banks on behalf of customers who had directed those from whom they bought goods to draw upon the bank, so putting into their hands a first-class security which could be easily negotiated. By thus placing its name at the disposal of a customer the bank earned a commission, and the customer was, of course, bound to put the bank in funds before the bill fell due; and the bank's liability to meet the bill was thus offset by the customer's liability to provide it with the wherewithal. By this means home and international trade were financed by the creation of bills of exchange, which have been called the currency of international trade, and the banks, as has been shown above, were enabled, by buying these bills under discount, to provide themselves with a convenient and liquid form of security which could be relied upon to produce cash at its due date. The special function of the banks, however, and the one with which the public is most familiar, was their provision of facilities for deposit, the creation of deposits by advances, and the transfer of such deposits from one to another by cheque. By this means they provided the commercial community with a money or currency that was safer and more convenient to handle than legal-tender cash. Bank deposits thus became potential currency which could be turned into actual currency by drawing a cheque.

The function of the accepting houses has already been described when the accepting business done by the banks was explained. The accepting houses accepted on behalf of customers in exactly the same way as the banks, but in their case this business was generally their chief if not their sole activity. Some of them, however, applied the connexions which they thus acquired abroad in acting as issuers of foreign loans. By accepting bills which were used in commercial payments all over the world they also were, in a sense, creators of credit and currency as long as their paper was readily taken and discounted. Many of the bills drawn on them were against goods or securities or gold going from one foreign country to another, or were drawn in anticipation of shipments of goods, or merely against the credit of the drawer and acceptor. In the two latter cases they were usually called "finance bills."

The position of the discount houses, also, is already to a great extent apparent. They, using their own capital and to a much greater extent money borrowed from banks and others, bought bills of exchange accepted by banks, accepting houses, merchants and traders, and either held them until maturity or sold them to banks and others who required a short investment that could be relied upon to become cash at due date. By the rate at which they borrowed from day to day or for short periods from the banks they established the rate for money in the market, and by the rate at which they bought bills they established the discount rate. As their most important lenders and their most important buyers of bills were the banks, it followed that the extent to which the banks were prepared to lend the money and buy bills had an important influence in fixing rates for loans and discounts.

Since there was no control by law in England over the extent to which the banks could create credit and since, as has been shown, they were able easily to increase their holding of cash at the Bank of England by calling in loans from the discount houses and so compelling them to borrow from the Bank of England, a temptation which was thus put before the banks to create too much credit had to be corrected by constant vigilance on the part of the Bank of England. In the case of all material commodities, cost of production is an influence against excessive supply at too low a price; in the case of credit, the creation of which is a matter of book-keeping, this consideration hardly arises, since no more clerical work is involved by an advance of a million than by one of a thousand pounds. Consequently an artificial check had to be provided by the regulation of the money market by the Bank of England. If the banks created too much credit, with the result that the discount rate in London declined to a point that was not justified by England's position in international trade, an excessive number of bills of exchange on London would be created and, being offered in foreign centres, would turn the foreign exchanges against London. Ultimately this process would correct itself because the depreciation of the exchanges would at a point cause exports of gold from England, so reducing the basis of credit and compelling the banks to restrict its creation. But it was not considered safe to leave the market to its own devices until this tardy remedy worked. The Bank of England, as custodian of the country's chief gold reserve, was accustomed when the exchanges threatened gold exports to raise its official rate of discount, so giving notice to the discount houses that if they were obliged to borrow from it they would have to pay more for the accommodation, and making them more careful about buying bills at too low rates. But if, owing to the flood of cheap money with which the discount houses were pro-

vided by the other banks, this warning did not suffice, the Bank of England was accustomed to take further action by borrowing money itself in the market and so artificially restricting the supply. By this means the level of rates in London was raised, with the result in normal times that a demand for bills on London was stimulated among foreign capitalists who wanted to lend funds there, the exchanges turned in London's favour, the threat of gold exports was reduced and, if the policy was maintained with sufficient determination, gold imports finally resulted, thus materially reinforcing the basis of credit.

*Effect of the World War.*—Such was the delicate machine into which war crashed like a bomb into a greenhouse. Its effects were immediate, and began, in fact, some days before a shot had been exchanged on the field of battle. England declared war on Tuesday, Aug. 4, but on the preceding Friday, July 31, the London Stock Exchange, which had remained open for business all through the Napoleonic wars, decided that it had to close before this war had even begun. The bourses of continental Europe had already set the example and the London Stock Exchange, which had been subjected to an enormous flood of continental selling, was unable to continue alone to bear the brunt of these realizations. It should be noted that the New York Exchange, though it was not then the international market that it has since become, but chiefly confined its operations to dealing in American securities, immediately followed London's lead. The effect on the banking position of the closing of the market in securities was twofold: In the first place the banks were unable to increase their cash resources by realizing their investments; in the second place they were unable to call in loans from stockbrokers and other customers who had given Stock Exchange securities by way of collateral pledge, owing to the inability of the borrowers to realize their security.

Thus one of the banking assets, which had been regarded as more or less liquid, had become unrealizable and frozen—partly, perhaps, owing to the action of the banks themselves, which were said to have increased the pressure of realization on the Stock Exchange by ruthless calling-in of loans, thus compelling their customers to sell securities pledged. This freezing process developed rapidly. The market in foreign exchange was already in a demoralized condition, and the consequence was that foreigners who owed money to England were unable to remit it, however hard they might try.

It has already been explained that, owing to the great international acceptance business which London has developed, the London banks and accepting houses accepted bills drawn by foreigners against shipments of goods from all parts of the world to England or in many cases from one oversea country to another, while a certain number of bills were also drawn, not against shipments of goods at all, but sometimes in anticipation of such shipments and sometimes merely in order to create credit against the wealth and prestige of the parties. The solvency of the London accepting houses thus depended to a certain extent on the ability of foreign customers to remit funds for meeting bills of exchange at their due date. Even when bills had been accepted on behalf of an English customer, who had arranged the credit for a foreigner, the position was almost equally unpleasant, because the British customer might be unable to supply the acceptor with the necessary funds if the foreign drawer was unable to remit. Thus the break-down of the machinery of foreign exchange inflicted a twofold blow upon the banks, because it raised considerable doubt concerning the value of the bills of exchange, which, as has already been shown, formed an asset on the highly liquid nature of which they had been wont to rely, and it also affected them as large acceptors themselves.

With their investments thus locked up by the closing of the stock market and their loans against securities an unrealizable asset and many of their bills of exchange a doubtful quantity, the London banks found themselves faced with an abnormal demand for cash on the part of the public. An extra demand for cash is, of course, usual during the last days of July, when many people are preparing to start for a holiday of many weeks and a still greater number are taking advantage of the Bank Holiday at the beginning of August for a few days' change. And some witnesses of this crisis have maintained that the public did not lose their heads and run upon the banks, but only asked for their usual cash requirements for the holiday; in some cases, however, bankers have admitted that the public were certainly taking more than usual, in the belief or delusion that their money would be safer in their own keeping than in that of the banks. And there is at least no doubt that the banks, very naturally frightened by the freezing of their assets, forgot or ignored the old banking tradition of meeting an abnormal demand for cash with the utmost readiness to pay it out in whatever form the public wished, and met the demands of their customers wholly or partly in Bank of England notes. This they were quite entitled to do, since Bank of England notes are legal tender, but since these notes were for sums of not less than five pounds they were an obviously inconvenient form of currency for holiday makers and there was consequently a crowd of applicants at the Bank of England wanting to change notes into gold.

One effect of the crisis which marked the beginning of the war was thus to cause a heavy drain on the Bank of England both for notes and gold, with the result that in the two weeks from July 24 to Aug. 7 the reserve of its banking department was reduced by nearly 20 millions and was brought down below 10 millions, though for many years previously 20 millions had been regarded as its danger-point. During the same period the Bank's stock of bullion in both departments was reduced by 12½ millions. At the same time demands upon it for advances and discounts were on a very large scale and its holding of other securities rose by nearly 32 millions. It was thus evident that special measures had to be taken for suspending the usual restrictions on the Bank's power to do business, and preparations were made for a suspension of the Bank Act, because it limited the amount of notes which the Bank was empowered to issue against securities. According to precedent this suspension could only be granted if Bank rate were raised to 10%, and consequently the public, whose nerves on the subject of finance were already sufficiently on edge, were startled by a rocket advance from 3 to 8 in Bank rate on Friday, July 31, and a further advance to 10% on Saturday, Aug. 1. This development was the more terrifying because movements in Bank rate on any other day but Thursday, or of more than 1% at a time, are quite exceptional. At the same time the belief that the Bank of England would always meet a crisis by lending freely was disproved by its action in refusing to lend money to bill-brokers who were being pressed by the banks to repay the loans and advances on which they relied as part of their working resources, though this refusal on the part of the Bank of England to provide emergency credit was only maintained for a very short time.

These chaotic conditions clearly had to be met with stronger measures than a mere suspension of the Bank Act. It has already been shown that five-pound notes are of very little use for ordinary currency purposes and that paper money of a smaller denomination was required in order to check the demand for gold. The measures taken included the prolonging of the August Bank Holiday for four days, during which, by reassuring statements from leading politicians of both parties, the publics' nerves, which had been unnecessarily shattered by too much respect for precedent, were soothed into composure. The Currency and Bank Notes Act of 1914 was passed, which suspended the Bank Act of 1844 by empowering the Bank of England and other banks of issue to issue notes "in excess of any limits fixed by law" so far as temporarily authorized by the Treasury and subject to any conditions attached to that authority. According to its published weekly returns the Bank of England never took advantage of this authority, its fiduciary issue being never shown above the £18,450,000 authorized under the terms of the Bank Act (1844). But it was stated by Mr. Asquith in Parliament in Nov. 1915 that there had been an excess issue of £3,043,000 above the legal limit during the crisis. The most important provision of the 1914 Act, however, was that which allowed an issue of £1 and 10s. currency notes by the Treasury which were to be legal tender in the United Kingdom for the payment of any

amount. They were also convertible on demand during office hours at the Bank of England into "gold coin, which is for the time being legal tender in the United Kingdom." At the same time postal orders were made temporarily legal tender and similarly convertible at the Bank of England into any legal-tender coin. By the terms of the Act, currency notes were to be issued to such persons and in such manner as the Treasury directed, but the amount of the notes issued was to be a floating charge in priority to all other charges on the assets of the recipient.

This provision was based on the belief that the Treasury notes would be issued by way of loan to bankers. An explanatory memorandum by the Treasury stated that "Currency notes are issued through the Bank of England to bankers as and when required up to a maximum limit not exceeding, in the case of any bank, 20% of its liabilities on deposit and current accounts. The amount of notes issued to each bank is treated as an advance by the Treasury to that bank, bearing interest from day to day at the current Bank rate. The bank is permitted to repay the whole or any part of the advance at any time." But in fact many of the banks never took out currency notes as a loan, but paid for them from the beginning with a draft on their balance at the Bank of England; and this soon became the usual and general way by which the notes went into circulation.

At the same time a general moratorium for postponement of payments was made by proclamation on Aug. 6, which provided that any payments due before that date or on any day before Sept. 4, in respect of any cheques or bills payable on demand drawn before the beginning of the 4th day of August, or in respect of any negotiable instrument, not being a bill of exchange, dated before that time, or in respect of any contract made before that time, should be deemed to be due and payable on a day one calendar month after the day on which the payment originally became due and payable, or on Sept. 4 1914, whichever was the later date. The proclamation did not apply to wages or salaries or to liabilities of less than £5 or to dividends or interest on stocks, funds or securities or to the liability of banks of issue in respect of bank-notes issued by them. This last-named provision is important as showing that the moratorium did not affect the convertibility of the Bank of England note. Any payments to be made by a Government department were also exempted from the moratorium. This general moratorium was afterwards continued for two more months. By its terms all danger of a continued run on the banks was stopped because the banks were enabled to exercise their own discretion as to meeting cheques drawn upon them in respect of money paid in before Aug. 4. Already, however, the public nervousness concerning the banking position had been allayed and it is an open question whether it was really necessary to give the banks the protection of a moratorium of which most of them made little or no use. On Aug. 7 Bank rate was reduced from 10 to 5%.

By these measures—the provision of new currency which the banks were empowered to take by way of loan from the Treasury to a much greater extent than they actually required and the suspension of payments—the situation between the banks and the public was effectively regulated. The more difficult and technical position arising from the position of the accepting houses, the banks as large acceptors of bills and the discount market, owing to the break-down of the machinery of exchange and the consequent inability of foreigners to make remittance, had been already met by a proclamation of Sunday, Aug. 2, for postponing the payment of bills of exchange by reacceptance for a month. On Aug. 13 a notice was published stating that the Government had agreed to guarantee the Bank of England against any loss incurred in discounting bills of exchange, "home or foreign, bank or trade, accepted prior to August 4, 1914," and that the Bank of England was prepared to discount "approved" bills accepted before Aug. 4 without recourse against the holders. By this measure all holders of such bills were able to dispose of them to the Bank of England and be quit of any liability in respect of them as is usually carried by all who endorse a bill. It was also stated that the Bank of England would be prepared "for this purpose to approve such bills of exchange as are customarily discounted by them and also good trade bills and the acceptances of such foreign and colonial firms and bank agencies as are established in Great Britain." It was found, however, that these measures did not sufficiently meet the position by restoring the machinery of acceptance and exchange and on Sept. 5 a fresh step was announced and the Bank of England, instead of merely buying bills accepted before the moratorium, lent money to acceptors to meet them with, so relieving not only the holders of the bills but also previous endorsers from liability. Moreover, the assets of the acceptors were to be subject to a first charge in favour of any bills drawn since the moratorium, and this provision naturally encouraged the creation of new bills by making pre-moratorium bills, the liability for which the Government had accepted, a second charge on the assets of the acceptors. The acceptors were not to be asked to repay these advances made to meet their pre-moratorium bills for a period "of one year after the close of the war," but in the meantime the acceptors were to be under obligation "to collect from their clients all the funds due to them as soon as possible, and to apply those funds to the repayment of advances made by the Bank of England." Interest was charged at 2% above the ruling Bank rate.

Such were the measures taken for dealing with the monetary crisis that preceded and accompanied the beginning of the war. It was then the general belief that the war could not last long, and that the business organization should be encouraged to proceed as far as possible as usual so that British trade should continue to be financed on the old lines with the ordinary machinery of exchange, acceptance and the discounting of commercial bills in Lombard Street. As the war went on, however, the money market became more and more a controlled establishment. As Government purchases of munitions, food, wool, etc., expanded, the credits drawn for their financing were naturally taken out of the hands of private enterprise and were created for the Government by means of Treasury bills, Ways and Means advances, and occasionally by bills drawn on and accepted by Government departments. Moreover, as the war went on and its cost increased, the Government found it necessary to prohibit new capital issues at home except such as were permitted by a Treasury Committee appointed to consider whether they were desirable from the point of view of the country's war efficiency and also to forbid the export of capital. All these measures and tendencies made a profound difference to the nature of the business done by the London money market. The diminished supply of what used to be called "bank" and "trade" bills, that is to say, bills drawn on banks, accepting houses, merchants and traders, was very much more than replaced by the enormous total of Treasury bills, of which there were 15 millions outstanding when the war began, 1,148 millions in Dec. 1916, and 1,124 millions at the date of the Armistice. The system had also been introduced by which the Treasury bills, instead of being offered occasionally for public tender, were on offer from day to day at rates fixed by the Treasury. Thus the discount market, instead of having to compete for bills, fluctuating in number according to the trade and financial demands of Great Britain and her foreign customers, and having to exercise judgment and experience in discriminating concerning the quality of the bills and the degree of favour with which they would be regarded by the banks and other buyers to whom it hoped in due course to sell most of them, had its business enormously simplified by the supply "on tap," in unlimited amounts, of Treasury bills with the credit of the Government behind them. The rate at which Treasury bills were offered became the dominant factor in the discount market. At the same time a new market for Treasury bills came into being, and a large part of the new supply was bought by contractors, shipowners and others who acquired big cash balances during the war. The following table shows the extent to which Treasury bills and Ways and Means advances were created during and after the war.

A still more profound change, and one which had much more important effects upon the general public and upon the whole course of British war finance, was the enormous extent to which the Government found it necessary to apply to the Bank of England

*Floating Debt Outstanding (million £)*

and to the other banks for assistance in providing the necessary funds. It has been shown above, in the analysis given of the pre-war working of our monetary system, that advances made by banks nearly always mean a corresponding addition in banking deposits and consequently an increase in the amount of money that the public can spend in the shape of the cheques that can be drawn against these deposits and are normally taken in payment for goods and services (*see* INFLATION). It is important to note that in so far as the Government got funds from the Bank of England on Ways and Means advances or Treasury bills or any other security on which the Bank lent to it, the credit basis on which all the other banks worked was thereby increased; because the money, as it was paid out to contractors and others to whom the Government owed it, was paid in by them to their own accounts with the outside banks, which thus received an increase in their cash at the Bank of England, which they could either hold as such or convert into currency notes; and so an advance was caused in the proportion between their cash and liabilities which encouraged them to expand the credit based on their increased cash holding. In the same way when the outside banks bought Treasury bills or Exchequer bonds or any other form of Government security issued, the result was an increase among their assets in their Government securities or bills discounted (if they included Treasury bills in this item), and a corresponding increase in the aggregate of banking deposits or potential money in the hands of the public, which was thus enabled to draw more cheques; because the money paid by banks for Treasury bills was paid first to the Government and by them paid out to the public, who were able to draw against it. It should also be noted that the outside banks were enabled by the increase in their cash at the Bank of England, caused by the new credits created by it for the Government, to take out currency notes and add them to their cash reserves, paying for them by transferring to the Government cash at the Bank of England.

By this process the whole principle on which the money market worked was radically altered in practice, though in theory the old checks and restrictions were still operative, and London remained throughout the war, on paper, a free market in gold with a banking system working on a convertible currency. It has already been stated that, though the Currency and Bank Notes Act of 1914 suspended the restrictions of the Bank Act of 1844, the Bank of England only availed itself of this suspension for a few hours and in all its published weekly returns showed a gold backing for every note issued above the legal limit of £18,450,000 on the fiduciary issue. Its notes were still convertible on demand, as were also the new currency notes, which were poured out in an almost steadily increasing volume through the process described above. There was during the war period no legal prohibition of gold exports, and so in theory anyone abroad who had a monetary claim on England could still turn his claim into legal-tender cash, turn the latter into gold and take the gold away. In fact, however, he would have found considerable difficulty in doing so, because the British public and banks had had impressed upon them the need for conserving the gold resources of the country for the purpose of financing abroad the war requirements of England and her Allies. The public had been effectively persuaded to pay in its gold holdings into its banks, and the banks and other professional financiers were restrained by patriotic and other considerations from applying to the Bank of England for gold in order to oblige a foreign customer or earn a profit in exchange; moreover, the possibility of profit in exchange was largely extinguished by Admiral Tirpitz and the submarine campaign, which did much—through the cost of freight and insurance—to maintain the convertibility of British currency during the war (*see* EXCHANGES, FOREIGN). The convertibility of British currency thus became a pious fiction, and its amount, in the form of legal-tender notes, was limited only by the extent to which the Bank of England created new credit for the Government and others; and, in the shape of cheques, by the extent to which the public drew on the ever-increasing deposits which the other banks created on the basis of the new cash and credit provided by the Treasury and the Bank of England. There was thus a constant tendency to increasing abundance of money of one kind or another, as will be seen from the appended tables.

The growing flood of new currency and credit tended to produce a low level of rates in the money market, which, if unchecked, would have cheapened the raising of the sinews of war, but would also have produced an adverse effect on the foreign exchanges by encouraging Britain's foreign creditors to take their balances home instead of employing them in London. From the point of view of British financial prestige, which was of the highest possible importance for the war, it was necessary to make every effort to keep the foreign exchanges favourable. For the purpose of financing the war cheaply at home there was much to be said for a policy of low rates in the money market. As has already been shown, the Government was practically the only borrower, since no other party could offer issues except with the permission of a Treasury Committee and the export of capital was forbidden. Thus, if the tendency towards ease had been allowed to take its course, the Government could apparently have secured for itself at low rates all the investment money that was available, especially if it had made use of the hint of compulsion so effectively employed by Mr. Bonar Law when he achieved the greatest borrowing success of the war at the beginning of 1917. This consideration, however, gave way, perhaps rightly, to the need for maintaining our prestige abroad as expressed by the foreign exchanges; rates in the money market, as will be shown, were artificially propped up, and it was not until the last year of the war that a system was adopted of differential rates for home and foreign money. In consequence of this system of considering the effect upon foreign exchanges as more important than the price that the Government had to pay for the funds that it needed, and a belief of bankers that, even at a time of war crisis, when no other borrowers were in the market, the only way to induce the public or professional financiers to subscribe for war securities was by offering them continually higher rates for their money, this crescendo movement continued until the autumn of 1916, when 6% was offered on an issue of Exchequer Bonds.

Such were the most important changes that affected the

working of the money market during the course of the war, and it now remains to sketch the history of these developments as they evolved. The effect of the measures taken for meeting the crisis of Aug. 1914 was to leave the market very amply supplied with funds created by the Bank of England for the assistance of the accepting houses for discounting pre-moratorium bills and for financing the Government. The "other deposits" at the Bank of England, which stood at 42 millions in the middle of July, had risen to 168 millions by the beginning of Dec., though they declined to 128 millions at the end of the year. Bank rate had been hastily reduced, from the 10% to which it had been raised on the eve of war, to 5% when business was reopened after the prolonged Bank Holiday of Aug. 1914, and remained at this point until July 1916. The market rate of discount for 3-months' bills had risen to 5½% at the end of July 1914 and first emerged into a quotable condition on Aug. 24 at 5%, rapidly descending to 3% by the middle of Sept. and ending the year 1914 at a shade over 2½%. A £350,000,000 War Loan at 3½% issued in Nov. of this year drew very little response from the public and a large part of it was taken by the Bank of England and was subsequently repaid to it out of the proceeds of the War Loan of 1915. By far the greater part of the advances under which the Treasury notes had been originally issued to the banks had been very promptly repaid and henceforward Treasury notes were almost entirely issued under the system already described in exchange for credit at the Bank of England. There were a considerable number of issues which raised their total outstanding to 117 millions. Ways and Means advances, of which 1 million were outstanding when the war began, had reached 58 millions on Dec. 31 1914.

In 1915 extreme ease and weakness of discount rates at first again prevailed. The market rate for 3 months was below 1⅝% in Feb. although Bank rate remained at 5% throughout the year. In April, however, the market was steadied by the beginning of the system under which Treasury bills were offered at fixed rates which were at first 2¾% for 3 months, 3⅜% for 6 months, 3¾% for 9 months. On May 8 12-months' Treasury bills were also put on continuous offer at 3¾ per cent. Towards the end of June the complexion of the market was altered by the appearance of the great 4½% War Loan offered by Mr. McKenna, who had become Chancellor of the Exchequer in May in succession to Mr. Lloyd George, who had taken charge of the newly created Ministry of Munitions. This loan, including conversions of 3½% War Loan, Consols, etc., produced total applications for 900 millions, the actual cash receipts being 585 millions. During the second half of 1915 the market rate for 3-months' bills was close up to Bank rate and rose above it in the middle of Nov., remaining so until the end of the year. By this movement the market was merely following the official fixed rate for Treasury bills on offer, which was raised to 4½% for all dates in Aug. and to 5% in November. An important new departure was instituted during this autumn by which the Bank of England took money from the other banks at a fixed rate. When the system began the terms were 4½% for a month, but the period was soon shortened to three days. By this means the rate for short money was effectively screwed up, since the banks naturally did not lend below the rate that they could get from the Bank of England; but its chief object was to get money direct for the Government at cheaper rates than on Treasury bills.

In 1916, with Treasury bills still "on tap" for all dates at 5%, the market rate remained steady slightly above that level until March, when the Treasury rates of discount were reduced to 4½% for 3 months, 4¾% for 6 and 9 months and 5% for 12 months. On this the market rate for 3 months promptly dipped to a shade above 4½%, and remained so until the middle of June, when it jumped to 5% again when the official rate for all dates was raised to 5. The first half of this year was notable for the beginning on Feb. 21 of the issue of War Savings Certificates for 15s. 6d., to be repaid at the end of five years at £1 or to be convertible into cash with interest accrued at any time after they had been held for a year. Since then the privilege of holding these certificates has been continued for another five years, at the end of which they will be repaid at £1 6s. By the issue of this ingenious and attractive security the savings of the poorest were brought to bear on the problem of war finance and an enormous increase has been secured in the number of citizens who have a stake in the country by being holders of Government obligations (*see* SAVINGS MOVEMENT). A campaign for the purpose of bringing home to all the need for saving during the war had been organized by the Parliamentary War Savings Committee in 1915

at the time of the issue of Mr. McKenna's 4½% War Loan, but had made little headway owing to the lack of a security in which the working classes could invest with a certainty of being able to get their money back in full at any time. This campaign was now taken up with much greater energy by the National War Savings Committee, which, with the assistance of thousands of devoted workers all over the country, especially among the teachers of the primary schools, did most satisfactory and effective work in securing savings for the war, so lessening the degree to which the war had to be financed by the creation of new credit by the Bank of England and the other banks.

The question of exchange was now requiring serious attention, and in July of this year bank rate was raised to 6%, partly owing to a rise in money rates in New York, which actually proved to be short-lived. An issue of 150 millions 6% Exchequer bonds repayable in Feb. 1920 was made in the following Oct., and provoked a good deal of criticism on the ground of the very high rate that was being offered to professional capitalists at a time when economy and self-denial for the war were being extensively preached. During this year, in accordance with the rise in bank rate, the rates at which Treasury bills were offered were raised on July 14 to 5½% for 3 months, 5¾% for 6 months and 6% for 12 months, but on Sept. 27 the official rates for all dates were reduced to 5½%; the 3 months' market rate closely followed as usual the rate for Treasury bills of that usance, being slightly below it for a few weeks in Nov. and at or above it during the rest of the half-year. A feature of this year's war finance was the expansion in Treasury bills and the absence of any great war loan.

In 1917 this system of financing the war largely by Treasury bills and entirely by short-date obligations was at once reversed by Mr. Bonar Law, who had become Chancellor of the Exchequer in succession to Mr. McKenna on the formation of the Coalition Government at the end of 1916. In the first days of 1917 the great 5% War Loan was issued, which realized over 1,000 millions. Mr. Bonar Law told a great meeting at the Guildhall, held to inaugurate the campaign for the placing of the loan, that the rate of 5¼% which it secured to subscribers at the issue price of 95 was as high a rate as they would get from British Government loans, and that if they did not subscribe on these terms the "resources of civilization were not exhausted"; this plain hint at compulsion was heartily cheered by a meeting largely composed of wealthy capitalists. Bank rate was brought down to 5½% in the middle of Jan. and to 5% at the beginning of April. The offer of Treasury bills was suspended altogether on Jan. 4, pending the issue of the War Loan, and the tender system was resumed for a short time, from March 30 to June 15, after which the daily sale was resumed at 4½% for 3 and 6 months' bills. No change was made in the rate which the Bank was giving to clearing bankers for surpluses until Feb. 26, when it was reduced from 5 to 4½%, coming down again to 4% on June 19. On each occasion the rate given by the Bank of England to banks outside the clearing was kept ½% below the rate given to the clearing banks. The market rate of discount fell from 5½% to 5% when the sale of Treasury bills was suspended, and showed renewed weakness in March owing to false hopes of easy money resulting from America's intervention. The huge transfers involved by the War Loan payments were carried out with surprising ease owing to arrangements enabling the banks to borrow from the Bank of England; moreover, the payments on War Loan were continually offset by the Government's disbursements and by the maturing of Treasury bills, the outstanding amount of which was reduced between Jan. 4 and April 14 from 1,093 millions to 454 millions; after that date they began to mount up rapidly again and by the end of the year again exceeded a thousand millions. The second half of 1917 was notable for the institution of a system of continuous borrowing from the beginning of October by issues of National War Bonds, by which the funds necessary for carrying on the war were to a great extent provided, without the disturbance and inflation caused by huge issues made largely with the assistance of credit manufactured by banks, even when the banks themselves were not practically compelled to make subscriptions to securities which involved an inconvenient lock-up of their funds. On Nov. 15 a special rate for foreign money was established by the Bank of England when it announced that it would allow 4½% on deposits of foreign money made through the clearing banks. This measure was a good deal criticised as impracticable, and could, of course, only have been attempted in war-time when patriotic sentiment put a strong bar upon all the openings for fraud which the system offered and when the existence of the censorship over foreign correspondence made it possible to trace any attempts to take advantage of them. In the last days of the year the rate at which Treasury bills were offered was reduced to 4% and there was a corresponding tumble in the market rate of discount. At the same time the rate given by the Bank of England to clearing banks was reduced from 4 to 3½ per cent. As the special rate for foreign money remained at 4½% there was thus established a considerable difference in the rates for home and foreign money; the more favourable terms which were thus made possible for home financing enabled a further reduction to be made in the Treasury bill rate on Feb. 4 1918 to 3½%, and the market rate of discount as usual followed suit; the Bank of England's rate on three-day loans from clearing banks also dropped to 3 per cent. At the end of May another important step was taken when the banks agreed that the special rate on deposits granted by many of them to favoured customers should be abandoned and that 3% should henceforward be the best rate that the clearing banks would grant. Arrangements were also made to bring the banks outside the clearing and the discount houses into line with this arrangement, which was made with a view to cheapening the supply of home money and stimulating the sale of war bonds. Another interesting monetary event was the appointment, brought about by the speed at which bank amalgamations were proceeding, of a committee to consider the question of their effect; its report, issued towards the end of May, made the recommendation, which was afterwards adopted, that in future all such amalgamations should only be permitted after receiving official sanction. In the second half of the year there was hardly any change in monetary conditions, with Treasury bills still on offer at 3½% and the market rate of discount steady at about that level. The Government continued to finance itself by means of the continuous issue of National War Bonds, which was highly successful, though it still left a gap to be filled by Treasury bills and Ways and Means advances. The Armistice was granted to Germany on Nov. 11 1918.

Thus at the end of the war the money market found itself expected to face the problems of peace in a highly water-logged condition. The gold standard was still theoretically existent, for both Bank of England notes and currency notes were by law convertible into gold on demand, and there was no legal prohibition of the export of gold, but the pre-war connexion between the amount of gold in the country and the fabric of credit that could be built upon it no longer existed. New credit had to be continually produced by the Bank of England to finance the inability of the Government to pay its way by taxation or by borrowing of saved money from genuine investors, and on this credit so produced the other banks expanded credit for their customers and so increased the amount of banking money in the form of cheques competing in the purchase of goods and services. Obviously the most efficient check on this process of expansion was reduction of Government expenditure to a point where it could be financed out of taxation and real borrowing. This policy, in fact, had been recommended by the report of a very strong Committee appointed, with Lord Cunliffe as chairman, in Jan. 1918, to consider problems connected with currency and foreign exchanges during the period of reconstruction and to report upon "the steps required to bring about the restoration of normal conditions in due course."

Its report appeared at the end of Oct. 1918 and stated that "the conditions necessary to the maintenance of an effective gold standard in this country no longer exist, and it is imperative that they should be restored without delay." To secure this end the Committee urged that Government borrowing should cease at the earliest possible moment and that a sinking fund should

be provided out of revenue for the annual reduction of debt, especially of the floating debt. Money needed for reconstruction purposes should not be provided by the creation of new credit and the shortage of real capital must be made good by genuine savings. Under an effective gold standard all export demands for gold must be met and foreign claims must be checked as before by the use of Bank rate. The Committee also pointed out that the differential rates for home and foreign money would be neither practicable nor desirable when the war was over. It recommended that all banks should transfer their gold holding to the Bank of England and that the principle of the Bank Charter Act should be maintained of a fixed amount of fiduciary issue, the amount of which was to be arrived at by experiment during the after-war period. The committee tentatively put forward 150 millions as a possible limit. It also suggested the transfer of the currency note issue from the Treasury to the Bank of England when once the amount of the fiduciary issue had been settled, and in the meantime recommended the policy of cautiously reducing the uncovered issue and replacing with Bank of England notes the securities with which it was then backed. The Committee's aim was thus in effect a restoration of the Bank Charter Act of 1844, with the suggestion that if the limit on the fiduciary note issue had at any time to be passed this should be done with Treasury sanction as under the Currency Act of 1914 instead of by a letter of indemnity from the Chancellor of the Exchequer. The conservatism of the report was naturally criticised by those who wanted to remodel the British monetary machine, but was on the whole well received in financial circles as indicating the way to return to a system which had worked so well until it was shattered by the war.

Very little had been done up to the middle of 1921 towards the adoption of these recommendations. During 1919 Government finance, by its failure to meet expenditure out of revenue, left the money market struggling under the double burden of financing official expenditure and meeting the needs of commercial customers who wanted to finance after-war enterprise. A Funding Loan brought out in the middle of the year produced only 473 millions, of which 92½ millions were subscribed by banks under official pressure. The Cunliffe Committee's insistence that demands for gold for export should be met was so far from being acted on that the gold standard was abandoned in March 1919 by the addition of gold coin and bullion to the list of articles which could only be exported under licence. This measure immediately followed the removal of artificial support of the price of sterling in New York. On the other hand, something was done towards restoring the money market to normal conditions. The rate given by the Bank of England to other banks for surplus balances was dropped on July 22 1919, and the special rate of 4½% given on foreign money was wholly abolished in Oct., having been dropped with regard to French, Italian and Belgian money in January. The latter part of this year also saw the inauguration of an attempt to improve the monetary position by making money officially dear, by raising the rate at which Treasury bills were offered and by putting Bank rate up from 5 to 6% in November. The idea behind this policy was apparently a desire, by making money dearer, to check speculation, credit expansion and the holding-up of commodities. Its critics pointed out that it was doubtful as a check on speculation in commodities at a time when rising prices were putting enormous profits into the pockets of those who were bold enough to back the advance, and if it checked speculation it would probably also check production and that the only certain result of it would be to cost the country some millions in financing the floating debt. In view of the enormous outstanding amount of Treasury bills the Bank of England's power to control the market by means of its rate was seriously weakened, because the holders of these bills by refusing to renew them when they fell due could at any time compel the Government to borrow from the Bank of England on Ways and Means advances in order to meet the maturing bills, and so increase the amount of cash at the Bank of England in the hands of the other banks, which they could if they chose convert into currency notes. This fact also weakened the effect of a Treasury minute which was produced at the end of this year putting a limit on the fiduciary issue of Treasury notes. Nevertheless there can be no doubt that the policy of the Treasury and the Bank of England in raising the level of money rates had a considerable psychological effect and brought home to many users of credit the fact that the policy of unlimited expansion was abnormal and would have to come to an end some day.

In 1920 another turn of the screw was applied by the raising of Bank rate to 7% in April, following a very large expansion in Ways and Means advances necessitated to meet Treasury bills which their holders had allowed to mature. This measure was shortly afterwards followed by a dramatic change in trade conditions from exuberance to depression, which was accentuated by industrial crises; but in spite of the very heavy fall in wholesale prices there was a further expansion in bank deposits, currency notes and the Bank of England's note circulation; the increase in this last item amounted to more than 41 millions, of which, however, 15 millions were put into the currency note reserve in accordance with the recommendation of the Cunliffe Committee. Moreover, the other banks, adopting another recommendation of the Cunliffe Committee, sent their holdings of gold to be added to the Bank of England's stock. These contributions, in exchange for which they took out notes, or increased their balances at the Bank of England, amounted to over 40 millions.

In 1921 the process of deflation began in earnest with reductions in the circulation of Bank of England notes and currency notes, and also in the deposits of the joint-stock banks, which from the beginning of this year revived the pre-war custom of monthly bank statements. The Bank rate was reduced to 6½% in April and would probably have come down to 6% soon after but for the long-drawn crisis in the coal-mining industry. The reduction to 6% was actually made on June 23. On July 21 the rate was reduced to 5½%, and in Nov. to 5 per cent.

If the London money market was thus a long way from restoration to its pre-war position it had certainly come much nearer to normal working by the end of 1921 than any of its European rivals. How it would fare in future competition with New York, enormously strengthened by the great mass of wealth that America had acquired at the expense of warring Europe, was a matter about which it was only possible then to make guesses, in the existing attenuated condition of international trade. Even in 1921, however, in spite of America's determination to finance her own trade and the measures taken to enable her to do so by the Federal Reserve Act, bills were still to be seen in Lombard Street drawn against shipments of goods from the East and from other foreign countries to the United States.

(H. W.)

**MONGOLIA** (*see* 18.711).—The economic development of Mongolia remains greatly restricted by lack of transport facilities, and the trade of the country must continue to be insignificant until railway communication is established between Kalgan and the Siberian railway. Passenger traffic by motor-cars between Kalgan and Urga (two days' run) had by 1921 been started by two Chinese companies, but trade was still carried by camel caravans, which take about a month on the journey.

*History.*—For several years before the overthrow of the Manchu dynasty, resentment against China's military and colonizing policy had steadily increased amongst the Mongol princes and their followers, who realized that China's systematic policy of peaceful penetration, if unchecked, must entail the gradual extinction of the autonomous rights conferred on their country by the Ta Ching emperors. Before the revolution in China, the misgivings and grievances of the Mongol chieftains had produced a definite separatist and nationalist movement in Outer Mongolia, which looked to Russia for support. The provocative attitude and actions of Santo, the Chinese resident at Urga, stiffened the opposition of the Mongol leaders, who rallied round their spiritual ruler, the Living Buddha (Hutukhtu). In July 1911 they despatched a secret mission to Petrograd, asking Russia's help to secure their independence. The outbreak of the revolution in China provided them with an opportunity for a *coup d'état*. Early in Dec. the Amban and other Chinese

officials, with their troops, were compelled to return to China, the Living Buddha was proclaimed ruler, and a Mongol Government of five ministers was formed at Urga. From the outset, however, differences of policy were manifested amongst the Mongol chieftains, one party being in favour of complete severance from China under Russian auspices, the other advocating a policy of reasonable compromise and conciliation towards the Government at Peking. These differences were frequently manifested in the subsequent course of events.

In May 1912 the Barguts threw off their allegiance to China, and Barga became part of the new dominion of the Urga Hutukhtu, who appointed a leading Bargut as his Amban at Hailar. Later in the year, the authority of the Urga Government was extended to Uliasutai and Kobdo. At this stage some fighting took place between the Mongols and the Chinese forces in the Altai district, where Prince Palta remained faithful to China; thereafter Peking was frequently alarmed by rumours that the Russian-trained Khalkas were planning an expedition in force from Urga southwards. In Aug. the first outbreak of rebellion occurred in Inner Mongolia (where most of the native princes had declared their adherence to the Chinese republic), but it was quickly suppressed by Chinese forces despatched from Chihli. Desultory fighting, accompanied by brigandage on both sides, continued thereafter in many parts of the country, generally to the advantage of the Mongols. Meanwhile Russia proceeded to recognize the *de facto* Government at Urga and to strengthen the independence movement, by concluding a convention with the Hutukhtu Lama direct (Nov. 3 1912), wherein the latter was recognized as sovereign of Mongolia and promised assistance in refusing to allow Chinese troops or colonists in Mongolian territory. Russia, on her side, was guaranteed full enjoyment of her former trade rights and privileges.

Several communications passed in 1912 between Peking and Urga, the Chinese Government endeavouring to restore amicable relations on the old footing, but without result. At this juncture the Russian representative at Peking intervened, endeavouring to persuade President Yuan Shih-K'ai's Government to recognize the *fait accompli* of Outer Mongolian autonomy in return for recognition of Chinese suzerainty over the whole country and a free hand in Inner Mongolia. *Mutatis mutandis*, the position of affairs created by the Chinese revolution in Mongolia was very similar to that produced in Tibet, it being manifest in both cases that the meaning of the words "suzerainty" and "autonomy" must eventually be determined by the forces behind them.

After protracted negotiations, the Chinese Government, making a virtue of necessity, signed an agreement with the Russian representative at Peking on Nov. 5 1913. By the Declaration and Notes of this agreement, Russia recognized Outer Mongolia as an integral part of Chinese territory under the suzerainty of China, whilst China recognized the autonomy of Outer Mongolia. Autonomous Outer Mongolia was defined as the districts heretofore known under Chinese administration as those of Urga, Kobdo, and Uliasutai. Russia undertook to use her influence with the Hutukhtu, to secure his acceptance of autonomy in lieu of the independence promised by the Russo-Mongolian agreement of Nov. 1912. In Sept. 1914, representatives of Russia, China and the Hutukhtu met at Kiakhta, where, after nine months of negotiations, a tripartite agreement was concluded on the lines proposed by Russia. A Chinese Resident-General was appointed to represent China as suzerain at Urga, with deputies at Kiakhta, Kobdo, and Uliasutai. Russian activities in Mongolia from 1912 to 1917 manifested a forward policy very similar to that displayed in Manchuria and Korea before the Russo-Japanese War, including in their scope arrangements whereby the railways, finance, communications and currency of Outer Mongolia would gradually be made subservient to Russian interests.

The collapse of Russia under Bolshevik rule necessarily entailed a complete change in the situation in Mongolia. On the one hand, it deprived the disaffected Mongol chieftains of the support of their powerful protector; on the other, it exposed Outer Mongolia to serious dangers of invasion by Germans and Bolsheviks from the Baikal region. The Chinese were not slow to take advantage of the opportunity thus created to restore their ascendency, and at the same time to take measures against "Red" incursions from the Russian border. The increasing disorders in Siberia and the retreat of the Czechs eastwards from Baikal in the autumn of 1918, led to a considerable increase of the Chinese garrisons at Urga and elsewhere. In June 1919 the Government of Outer Mongolia invoked the assistance of the Chinese officials to check the increasing activities of the Buriat and other marauders; a considerable Chinese force was therefore despatched from Chihli and Moukden. The northern Chinese Tuchuns assumed the task of protecting Mongolia from the Bolshevik invasion and also from Gen. Semenoff, the Ataman of the Transbaikal Cossacks, who was recruiting a large force of Russian refugees and Buriats at Kiakhta, ostensibly in support of the Pan-Mongol movement, but actually with the object of establishing an anti-Bolshevik Russian province and a new base of military operations. At the beginning of Nov. 1919, there were 4,000 Chinese troops in Outer Mongolia. On Nov. 15, the Chinese resident at Urga presented an ultimatum to the Mongolian Government, requiring them to renounce their claim to independence, failing which the Living Buddha and the prime minister would be conveyed in custody to Peking. The Hutukhtu was opposed to compliance and several of the leading princes were inclined to support his resistance; but the Council of Ministers, finding itself between the deep sea of Chinese domination and the devil of Semenoff's invasion, decided, against the Hutukhtu's wishes, to sign the memorial required of them. On Nov. 22 a Presidential Mandate was issued at Peking, announcing the receipt of this memorial, and approving its proposals. Mongolian autonomy was therefore cancelled and all agreements and treaties, concluded by or with the Government at Urga since the declaration of Mongolian independence, were declared null and void. On the 24th the Russian representative at Peking filed a protest against this mandate, reserving on behalf of Russia all her treaty rights in Mongolia, to be reasserted hereafter.

It is probable that if the Chinese had displayed a reasonable and conciliatory spirit at this juncture, the Mongols might have been content with a position of partnership in the Chinese republic; but the arrogance and brutality displayed by the Chinese military commander, Hsü Shu tseng (commonly known at Peking as "little Hsü") drove them to make common cause with the Russian refugees, and their Buriat and Japanese allies, against the Chinese. Matters reached a crisis in Oct. 1920, when Urga was attacked by Baron Ungern with a small body of Russians (originally belonging to Ataman Semenoff's force), a few Japanese officers and several thousand Buriats and Mongols. The Chinese retaliated by making the Living Buddha a hostage; for the next few months the Chinese garrison so looted and maltreated the civilian population of Urga that, after the escape of the Hutukhtu in Jan., every man's hand was turned against them. On Feb. 19 1921 the city was captured by Baron Ungern's forces and only a remnant of the garrison escaped.

On Feb. 25 the Hutukhtu was proclaimed as sovereign of the independent kingdom of Mongolia. Baron Ungern was appointed to the chief command of the Mongolian forces, and orders were issued by the Hutukhtu for the organization of a national army with compulsory military service. Mongolian troops subsequently occupied Ude, in the Gobi desert, and were threatening Kalgan. The helplessness of the Peking Government was plainly manifest; nevertheless, it declined the help of a Russian "Red" army, proffered by the Soviet Government's representative at Peking (M. Yourin) and in subsequent *pourparlers* with Mongolia, expressed its willingness to revert to the terms of the Kiakhta agreement. The leading Mongol princes, however, refused these overtures and declared their intention to maintain the complete independence of their country, at least until the restoration of the monarchy in China. (J. O. P. B.)

**MONOD, GABRIEL** (1844–1912), French historian (*see* 18.730), published in 1903 his *Souvenirs d'adolescence*, and in 1905 *Études sur Michelet, sa vie et ses Œuvres*. He died in Paris April 10 1912.

**MONRO, SIR CHARLES CARMICHAEL** (1860– ), British general, was born June 15 1860 and joined the army in 1879. In 1897–8 he saw service at Malakand, in the Mohmand country, in Bajaur and in Tirah, and he was on the staff in S. Africa during the war, for which he was promoted brevet lieutenant-colonel. He was afterwards commandant of the School of Musketry, and he commanded a brigade from 1907 to 1911. Promoted major-general in 1910, he had charge of a Territorial division in 1912–3 and was then transferred from this to the II. Div. of the Expeditionary Force, which he commanded in the first campaign in France in 1914. On the splitting up of General French's forces into two armies at the end of 1914, Monro was placed in command of the I. Army Corps, and he was shortly afterwards given the K.C.B. Then, on a III. Army being organized in July 1915, having acquitted himself admirably as a divisional and as a corps commander in the field, he was given charge of this. He, however, occupied the position for only three months, as he was chosen in October to take over command of the Mediterranean Expeditionary Force and to decide whether the campaign in the Gallipoli Peninsula was to be continued; he was at the same time promoted lieutenant-general for distinguished service. Monro now acted with rare decision under most difficult circumstances. Although the Government was disposed to cling to the peninsula he insisted upon its abandonment, and he was after some delay allowed to have his way,

with the result that the forces were withdrawn from a most dangerous position without appreciable loss under his general superintendence. His great services on this occasion were recognized by his being given the G.C.M.G., and then, having accomplished what was required in the Near East, he returned to the western front to succeed Sir Douglas Haig in command of the I. Army. He served in that capacity until Oct. 1916, when he was selected to be commander-in-chief in India, with the rank of full general.

In his new sphere of responsibility Sir Charles Monro proved himself to be a military administrator of the foremost rank. By untiring energy and skilful organization he succeeded in adding substantially to the strength of the native army, in creating a number of fresh regiments, and in greatly developing the non-combatant and hospital services on progressive lines. The consequence was that he was enabled to dispatch considerable and badly needed reinforcements to Mesopotamia and to Egypt and Palestine; the triumphs gained by General Allenby in Syria after he had been obliged to send off a large part of his army to the western front in the spring of 1918, were indeed in no small measure due to the work that had been accomplished by the commander-in-chief in India. Monro received the G.C.B. and he remained in India until 1920, when he returned to England.

**MONTAGU, EDWIN SAMUEL** (1879– ), English politician, second son of the 1st Lord Swaythling, was born Feb. 6 1879 and educated at Clifton, at the City of London School, and at Trinity College, Cambridge. At Cambridge he was president of the Union and acquired a considerable reputation for ability; and when he entered Parliament in 1906, at the age of 27, as Liberal member for the Chesterton division of Cambridgeshire, he was chosen by Mr. Asquith, then Chancellor of the Exchequer, as his parliamentary secretary, and continued in that position when his chief succeeded to the premiership. Early in 1910 he was appointed Under-Secretary for India, at a time when Lord Morley's tenure of the Secretaryship of State for India was drawing to a close. He remained in the post, under Lord Crewe as Lord Morley's successor, till 1914; and so made his first official acquaintance with India under the influence of Lord Morley's reforms and Lord Crewe's Durbar changes of 1911. As both his chiefs were in the Lords, he was the spokesman of the office in the Commons, and he acquitted himself well. That he might equip himself the more completely for his duties, he took the unusual course of visiting India in person. In his Indian budget speech of 1913 he remarked with true insight that the watchword of the future was coöperation between the Government and the governed in India; the difficulty was that in India men of the 20th century lived side by side with men of the 5th. At the beginning of 1914 he was promoted to the responsible post of financial secretary to the Treasury, in which capacity he was of material assistance in the financial improvisation which had to be effected in the early days of the war. Early in the next year he was made Chancellor of the Duchy of Lancaster, but when the first Coalition Ministry was formed he returned to his former post at the Treasury. Thence he was promoted, in the summer of 1916, to the headship of the office of Munitions and a seat on the War Committee of the Cabinet, on Mr. Lloyd George's succession to the Secretaryship of State for War. But when Mr. Asquith's Ministry fell he retired from office along with that minister's principal colleagues. The next summer, however, on Mr. Austen Chamberlain's resignation owing to the Mesopotamia report, he returned to the India Office as Secretary of State and began a tenure of that post which will always be memorable in Indian annals. It was felt that the wholehearted manner in which India, her princes and peoples, had flung themselves into the Imperial quarrel with Germany demanded a reconsideration of the relations between her and England. The new Secretary of State visited India in the following winter for the second time, and held prolonged conferences with the Viceroy, Lord Chelmsford, the leading members of the Indian civil service, ruling princes, and native politicians, and along with the Viceroy received deputations and memoranda from all classes. Ultimately in July 1918 there was published an elaborate report, drawn up and signed by the Viceroy as well as by the Secretary of State, recommending a series of constitutional reforms which should give the Indian peoples a large and real share in their own government. The report was received so cordially in the House of Commons that Mr. Montagu was able to claim at the end of the debate as "a remarkable fact" that all speakers admitted the principle of self-government for India. In India itself opinion was more divided, both among the English and among the Indians; but there was a large moderate section among both which welcomed the proposed reforms. In Dec. 1919 he had the satisfaction of passing the Government of India bill, embodying the recommendations of the report, through Parliament, and on its third reading he described it as a step in the discharge of our trusteeship for India; the ultimate justification of our rule would be in the capacity of the Indian peoples to govern themselves. When the new councils were established and beginning to work, he strongly set his face against any meddling with their proceedings by questions and answers in Parliament. When Lord Reading, the Lord Chief Justice of England, also a Jew, was appointed Viceroy of India in 1921, there was some public criticism, and it was suggested that Mr. Montagu might be moved to another office; but no change took place. He married in 1915 Beatrice Venetia, youngest daughter of the 4th Baron Sheffield.

**MONTANA** (*see* 18.752).—In 1920 Montana had a pop. of 548,889, an increase of 172,836 or 46% during the decade. The urban pop. was 172,011 or 31·3%, the rural 376,878 or 68·7%. In 1910 the ratio was 35·5% urban and 64·5% rural. The relative increase of rural pop. over urban was due largely to the immigration of an agricultural pop., particularly to the eastern part of the state. The total number of foreign-born whites in 1920 was 93,620. In 1920 there were 12 cities with a pop. of 5,000 or more, of which 6 had over 10,000. These 6, with their increase in the preceding decade, were as follows:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Butte | 41,611 | 39,165 | 6·2 |
| Great Falls | 24,121 | 13,948 | 72·9 |
| Billings | 15,100 | 10,031 | 50·5 |
| Missoula | 12,668 | 12,869 | −1·6 |
| Helena | 12,037 | 12,515 | −3·8 |
| Anaconda | 11,668 | 10,134 | 15·1 |

In 1910 Montana had 28 counties, in 1920 54. In 1920 only 16 counties had cities of more than 2,500 population. Most of the new counties have been formed in the eastern part of the state by the division of the large counties of Teton, Chouteau, Valley, Dawson, Custer, and Rosebud.

*Agriculture and Irrigation.*—By the census of 1920 there were 57,677 farms in Montana with an aggregate of 35,070,656 ac., of which 11,007,278 ac. were improved. This contrasts with 26,214 farms, containing 13,545,603 ac., of which 3,640,309 ac. were improved in 1910. The value of all farm property in 1920 was $985,961,308 as compared with $347,828,770 in 1910. Of the improved land only about 4,000,000 ac. were under cultivation and the remainder was used for pasture or allowed to lie fallow. More than 3,000,000 ac. were planted to wheat and hay. In 1919 the value of all crops was placed at $69,975,185. For the 10-year period 1909–18 the average yield per ac. was 21·8 bus. for wheat, 40·6 bus. for oats and 140 bus. for potatoes. Farms reporting land with drainage in 1920 numbered 756, or 1·3% of total; farms needing drainage numbered 1,728, or 3%. Approximately 1,700,000 ac. were under irrigation, but projects were under way to irrigate about 30,000,000 ac. of tillable land of Montana, of which about 7,000,000 ac. are capable of being irrigated. Of the area covered by these projects about 1,000,000 ac. were included in seven great Federal reclamation districts, the total outlay on which was estimated at $16,000,000. Under the Carey Land Act the state has undertaken to irrigate 162,285 acres. About half of this land was under irrigation in 1920, and about 25,000 ac. were open to settlement. In 1921 there were no large bodies of irrigable land such as would attract the attention of the Federal Government or of capital under the Carey Act, and further development of irrigation must be by small units. In 1919 the Legislature provided for a State Irrigation Commission to advise and assist in the development of irrigation in districts where the farmers wish to carry on such projects. In 1920 the Commission estimated that under this law a beginning had been made to bring 200,000 ac. under

irrigation. Stock-raising in general retained its importance during the decade ending with 1920, but the open range was largely superseded by the fenced ranch. The number of sheep declined from 4,959,835 in 1910 to 2,082,919 in 1920 but the number of cattle increased from 860,521 to 1,268,516, and the number of horses from 304,239 to 668,723. The total value of all live stock in 1920 was $150,000,000. The clip of wool for 1919 was valued at $10,229,632, and the dairy products at $7,534,413.

*Forests and Lumbering.*—One-sixth of Montana, or 15,957,196 ac., is included within the national forests. The state owns about 500,000 ac. of forest land and there is about 5,000,000 ac. in private hands. The total stand of lumber is estimated at 58,071,000,000 feet. A part of this forest area is also valuable for agricultural land and will be so used when the timber is removed. The remainder will be reforested as the old trees are cut.

*Mines.*—The World War gave a great impetus to the production of copper and other metals, but after the Armistice mining suffered an acute decline. The output of copper decreased from 323,174,850 lb. in 1918 to 180,240,000 in 1919, a decrease in value from $80,000,000 to $34,000,000. The production of lead increased from 37,135,875 lb. in 1918 to 42,163,000 lb. in 1919 but its value decreased from $2,636,000 to $2,411,000. In 1918 the output of zinc was 209,258,000 lb. and in 1919 it was only 176,000,000 lb. Its value decreased from $19,000,000 to $13,000,000. Silver-mining continued active and in 1919 the value of the output was $15,000,000. The value of gold decreased from $3,104,000 in 1918 to $2,272,000 in 1919. At the end of 1920 it appeared that mining must undergo a still greater depression. Natural gas is found at Havre, Glasgow and Baker. Oil was found in Elk Basin, Carbon county, in 1915. In 1919 a new and promising field was opened up in the Cat Creek district of Fergus county. At the close of 1920 the total oil production of the state was about 6,000 bar. per day. Many new wells were projected for the spring of 1921.

*Manufactures.*—The vast supplies of water-power in Montana give hopes of great industrial development. The hydro-electric plants in 1920 had a capacity of 300,000 H.P. Much of this was used for the operation of electric trains. In 1920 Congress passed a bill authorizing the Secretary of the Interior to lease the undeveloped power sites and the completion of such enterprises will add greatly to the electric power available for manufacture. In 1909 the total value of manufactures was $73,000,000; in 1919 it had increased to $200,000,000. In 1920 there were 195 lumber-mills, 75 flour-mills, 31 creameries, 7 cheese factories, 2 canning factories, 1 sugar-beet factory, 1 factory for the manufacture of acid phosphate fertilizers, 1 dynamite factory, and a number of brick and tile plants. The most promising field for manufacture appeared to be products of copper and wood. One plant for turning out copper rods and wire had a capacity of 6,000,000 lb. of copper per month. Montana mills produced only about one-half the lumber consumed in the state. High freight rates have retarded the shipment of Montana lumber to eastern markets.

*Education.*—In 1920 the Russell Sage Foundation of New York ranked the Montana schools as first among all the public school systems of America. The public-school fund belonging to the state amounted (1921) to about $20,000,000 and was increasing by the sale of school lands and by grants from the state. There were still unsold about 4,000,000 ac. of school land. The income from this endowment and from leases of school land was nearly $1,000,000 each year. In 1910 there were 60,678 children attending school out of a school pop. of 93,371. In 1919 there were 120,000 in school out of a school pop. of 161,626. In 1920 there were 81 accredited district high schools and 18 county high schools in the state. In 1912 Pres. E. B. Craighead, of the State University, started a campaign for the consolidation of all the state institutions of higher education into one university. His plan was defeated, but all the institutions were placed under one administrative head called the chancellor. Edward C. Elliott became the first chancellor of the "greater" university of Montana. In 1920 the people voted a tax of 1·5 mills on the dollar for the support of this university and a bond issue of $3,750,000 for buildings at the various institutions.

*Legislation.*—In 1921, when the new administration took charge of the Government, the state faced a deficit of $2,500,000. Governor Dixon proposed to relieve this by an income tax and by a tax on the production of oil wells and of coal and metal mines. The Legislature opposed these recommendations as radical, but finally agreed to a small tax on oil and coal production. The state has made steady progress in labour legislation. In 1911 the Legislature provided an eight-hour day for miners. In 1914 the state limited the working-day for women in factories, laundries, and stores to nine hours, and in 1917 reduced this to eight hours. By a law of 1919 children under 16 years who have not finished the eighth grade must remain in school. In 1915 a Workmen's Compensation bill was enacted which relieved those engaged in hazardous occupations from the necessity of suing for damages in case of injury. Farm legislation has been enacted to meet the more serious complaints of the farmer. In 1915 provision was made for state inspection and grading of grain, and a Farm Loan Act was passed. In 1917 the state provided insurance against hail for farmers. In 1921 the Legislature established a state Department of Agriculture with the understanding that a "real" farmer should be at its head. In 1911 the Legislature authorized cities to adopt the commission form of government, and in 1917 sanctioned the commission-manager plan. In 1912 the people established through the initiative a system for direct primaries for the nomination of all state and local officials and to express their preference for presidential candidates. They also passed a rigid Corrupt Practices Act limiting campaign expenses, providing for their publicity, and forbidding electioneering on election day. In 1914 the people ratified an amendment to the constitution to provide for woman-suffrage. The most important social legislation between 1910 and 1920 included the following: A rigorous White Slave Act to check commercial vice within the state and an Act raising the age of consent to 18 years; a stringent pure Food and Drug Act; a Mothers' Pension law supported in part by a tax on bachelors; a Teachers' Retirement Pension law; an Act to provide for the establishment and maintenance of county libraries, and state prohibition of the manufacture and sale of alcoholic liquors.

*History.*—Montana entered upon the second decade of the 20th century under very prosperous conditions. A new railway had just been built across the state. Mines were operating successfully, and there was a growing demand for Montana lumber. Great irrigation projects were under way, and in many sections of the state dry-farming was proving a success. The World War stimulated the mining and lumber industries, but it put a stop to the great reclamation works. During the later years of the decade drought seriously hampered the dry-land farmers and there was a decline in farm production. In 1910 there was a strong opposition to the national policy of conservation. Many people believed that the prosperity of the state depended upon the rapid exploitation of the power sites, the forests and the mines. They urged also that these natural resources should belong to the state. On the other side the conservationists urged that if the Federal Government turned over the natural resources to the state they would soon pass into the hands of a small group of eastern capitalists. They believed also that Federal administration would more nearly assure all the people of a share in them. The larger business interests have in general opposed the Federal conservation policy, particularly as applied to power sites and mineral lands, and most of these have passed out of Federal control. The people, however, came to approve the policy of the national forest service. State politics have largely hinged upon matters of taxation, particularly the taxation of mines. The constitution provides that mines "shall be taxed at the price paid the United States therefor," although the "net proceeds. . . shall be taxed as provided by law." The mining interests maintain that, since mining is a speculative business and the mines are being gradually exhausted, the net proceeds should be taxed at no higher rate than real estate or personal property. Their opponents maintain that since practically no tax is imposed on mines as such, the tax on "net proceeds" should be much higher than the property tax. Farmers complain that when business is poor the mines escape taxation by curtailing production, while poor crops and bad markets in no wise relieve them of their tax burdens.

During the World War a new radical movement spread over the state under the name of the "Non-Partisan League." It started first among the farmers but soon extended among the labour groups. In 1918 it elected a number of members of the state Legislature. In 1920 the farmers and labour men went into the Democratic primaries and nominated a former U.S. district attorney, Burton K. Wheeler, for governor. The Non-Partisan programme demanded for the labourer a more liberal workmen's compensation law and better sanitary conditions in lumber and construction camps. For the farmer it demanded exemption of farm improvements from taxation and a farm-bank system. The merchants and other business interests organized the Montana Development Association to oppose the Non-Partisan League. This organization supported Joseph M. Dixon, former senator and manager of Roosevelt's campaign in 1912, for governor on the Republican ticket. The Republican platform declared for a Conservative programme, and on this issue the entire Republican ticket was elected. In 1914 Jeanette Rankin was elected representative to Congress as a Republican, the first woman to be a member of that body.

For the World War Montana supplied in the neighbourhood of 40,000 soldiers, and subscribed in Liberty Bonds and Victory

Notes $87,406,650, as compared with an allotment of $56,165,450. The governors of Montana after 1910 were as follows: Edwin L. Norris (Dem.) 1909–13; Sam V. Stewart (Dem.) 1913–21; Joseph M. Dixon (Rep.) 1921– .

See Helen F. Sanders, *History of Montana* (3 vols., 1913), and the annual reports of the Montana Department of Agriculture and Publicity on *Resources of Montana*. (P. C. P.)

**MONTENEGRO** (*see* 18.766).—The former kingdom of *Crnagora* (Black Mountain), as it is known to its inhabitants, was by the Peace Treaty of 1919 merged in the kingdom of the Serbs, Croats and Slovenes (*see* YUGOSLAVIA).

*Area and Population.*—After the Balkan Wars of 1912–3 Montenegro obtained an accession of territory on the S.E. from the province of Scutari and on the N. and N.E. from Novibazar and Kossovo, which raised its area to an estimated total of 5,603 sq.m., the new Serbo-Montenegro frontier being settled by the treaty of Nov. 12 1913. Starting from the meeting-point of the former frontiers of Montenegro, Bosnia and the sanjak of Novibazar the new boundary followed the common frontier of the two latter provinces to the neighbourhood of Banich eastward of Chaynicha (Čajniče); it then cut the sanjak in a south-easterly direction passing N. of Plevlye and S. of Priyepolye across the headwaters of the Ibar to the Albanian Alps, descended to the White Drin in the neighbourhood of Klina and followed the river to its junction with the Erenik south-eastward of Dyakovitsa, thence striking north-westward to the summit of the Albanian Alps, which it followed to a point south of Gusinye, where it turned northward across the upper valley of the Lim, westward of Gusinye, to the old frontier which it left at a point east of Dinoshi, so as to enclose in Montenegro the tribes of Hoti and Gruda, to pass to the lake of Scutari, which it crossed to a point E. of Skya, and so to the Boyana south of Goritsa.

These additions of territory added to the population an element distinguished in certain respects from the inhabitants of the former kingdom. In historic Montenegro, the districts of Katun, Ryeka and Lyeshanska, situate roughly between the valley of the Zeta, the lake of Scutari, and the Bocche di Cattaro, the tribal system had persisted to the present day, but the smallness of the area, its lack of fertility, the fact that it is divided into distinct basins of limited extent, coupled with the impossibility of expansion at the expense of neighbours under Turkish or Venetian rule, or of the northern tribes, had for result that the individual tribes are numerically small. In the regions acquired after the Russo-Turkish War—in the N.W. and in the N.E., the latter known as the Brda, "the mountains"—the population was also organized on a tribal basis but the individual tribes, as for example the well-known Kuchi and Vasoyevichi, were larger, for here were large pastures, wood, water and a more generous soil, and the tribes, moreover, had succeeded in absorbing some of their neighbours over their open frontier towards the basins of the Tara and Lim, where the population was not organized on a tribal basis. The northern tribes of the Brda are also distinguished by their costume, which is of white braided with black, similar to that of the northern Albanian tribes, many of whom, in fact, claim a common origin with certain of the Montenegrin tribes, whom they resemble also in their physical attributes.

Professor Cvijić has pointed out (*La Péninsule Balkanique*, Livre II., chap. iv.) that most of the tribes represent an amalgam, sometimes of different Serb clans, sometimes of such clans which have absorbed earlier tribal elements which, in some cases, themselves were the result of the absorption of pre-Slav ingredients by the early Serb invaders, though the popular belief is that each tribe represents the descendants of one common tribal ancestor. In the greater part of the territory acquired after the Balkan Wars the Serb population has long lost its tribal organization, the people of the Metohiya forming part of the Serb population of Stara Srbija (Old Serbia)—the Kossovo-Metohiya type of Cvijić—while only a portion of the population in the acquired part of the sanjak is tribal, the remainder belonging to Cvijić's "Era" (Highland) type which extends from the south-westerly regions of the pre-1913 kingdom of Serbia over the sanjak and the Herzegovina. The new boundaries of Montenegro in this direction were quite artificial and determined largely by the line of demarcation between the zones occupied by the Serb and Montenegrin armies respectively. In these new acquisitions are many Albanians, especially in the Pech (Peć)-Dyakovitsa region. The official return for the population in 1920 was 435,000.

*Recent History.*—The last years of the history of Montenegro as an independent kingdom were marked by the great growth of a purely dynastic policy carried out by the sovereign to whom the organs of government provided by the constitution were entirely subservient. In his early years Prince Nicholas, true to the traditions of his predecessor and the sentiments of his people, had been a Southern Slav, or rather Pan-Serb, patriot who looked to the restoration of the Serb empire of Tsar Dushan. In 1865 an agreement was actually reached with Prince Michael of Serbia, which provided for the abdication of Nicholas, if ever the two States should achieve a common frontier and physical union become a possibility. Gifted with no small measure of the literary ability of his family he dedicated his gifts to the dissemination of his patriotic ideals. His song "Onamo Onamo" ("Yonder, Yonder"), spoke of Prizren the Tsarigrad over the mountains and became a popular classic, while in his play *Carica Balkanska* (*The Empress of the Balkans*) he envisaged the renewal of the old glories of the Serb race. Before the end of the century, however, a change of attitude became apparent. Under the last two Obrenovich sovereigns the reputation of Serbia and of its ruling House suffered eclipse, domestic scandals followed hard upon military disaster, and Prince Nicholas himself began to aspire to the leadership of the Serb race. With King Milan his relations were never good, and they were scarcely better with King Alexander. The brilliant marriages made by his daughters enhanced his sense of dynastic importance; and in particular the marriage in 1896 of the Princess Helena to the King of Italy, then Prince of Naples, fortified his diplomatic and international position by the support of a neighbouring Great Power with interests of its own across the Adriatic. The assumption of the style of "Royal Highness" by Nicholas on Dec. 19 1900 was an overt sign of the developments.

The beginning of the century was thus marked by the open adoption of a dynastic policy, by rivalry with Serbia, and by the close relationship formed by Italy with the little principality which was to form her *point d'appui* in the Balkans. The accession of King Peter to the throne of Serbia failed to effect any change in the relations between the two countries, which became worse than ever, and culminated in the scandal of the "Cettigne Plot" in 1908. At this point the history of Montenegro became involved with the movements and intrigues which were to culminate in the World War. Ever since 1903 the rising tide of the Southern Slav renascence had been flowing swiftly. Two years later, following on the resolutions of Fiume and Zara, the Serbo-Croat coalition was formed in the Croatian Sabor (Diet) and similar coöperation was arranged for in the other provinces of the Slovenski Yug (Slavonic South). Thus the Austro-Magyar policy of *Divide et impera*, which aimed at keeping the Orthodox Serbs and Catholic Croats apart and mutually hostile, had sustained a disastrous check. In 1906 Count Goluchowski was succeeded as Foreign Minister in Vienna by Baron Aehrenthal, an able man without scruples, and determined upon a forward policy for the monarchy. In the early part of 1908, a violent press campaign was waged in the monarchy against Serbia, coupled with denunciations of a vast and dangerous Pan-Serb conspiracy in the Southern Slav provinces directed from Belgrade.

In the spring of the same year some bombs were discovered at Cettigne, and there followed the famous High Treason trial which was the precursor of the Agram treason trial and the Friedjung case. The principal witness was a certain George Nastich, a Bosnian police spy and *agent provocateur* who in Dec. 1906 had been ostensibly expelled from Bosnia whence he proceeded to Belgrade. Here, according to his own account, he became a member of a revolutionary society known as the Slovenski Yug (in reality a literary society with propagandist aims) which was hatching a plot against the Dual Monarchy, the principal means of which was to be the employment of bombs, which were manufactured in the arsenal of Kraguyevats. The King of Serbia and the Crown Prince George were eager patrons of this society—which aimed at a republic. Eventually it was decided to use the bombs against the Montenegrin royal family—the time and place being so chosen as to destroy also King Peter's only daughter—and Nastich in disgust, after returning to Bosnia, put himself in communication with the Montenegrin police, and on the "discovery" of the bombs testified that these were the identical bombs whose manufacture he had witnessed. Nastich figured also in the other two trials mentioned above, in which also the Slovenski Yug appeared as the criminal agency at work, his information being thus connected with the Forgách-Vasich forgeries and forming part of the same general plan. The object of Aehrenthal was to preju-

dice Serbia and its dynasty as incurably regicidal, to estrange the two Serb States and to create an atmosphere in which his designs should appear legitimate and necessary; that of Nicholas was to strike at his internal opponents and to prepare the way to his headship of the Serbs. It is from its connexion with the wide issues at stake, and as being the first of a long series of similar incidents culminating in the tragedy of Sarajevo (perpetrated by the son of another Bosnian police spy), that the Cettigne trial derives its importance.

Later in the year followed the annexation of Bosnia and the proclamation of Bulgarian independence. In the effervescence which followed, Montenegro stood by Serbia, and in the settlement of the "annexation crisis" obtained the suppression of Article 29 of the Treaty of Berlin which established an Austrian tutelage over her coast and maritime administration. On Aug. 28 1910 Prince Nicholas took the title of king, encouraged thereto by Austria which saw in the kingly style an additional hindrance to a future union with Serbia.

It had early become evident that for the Young Turks liberal reform was but a pretext; that their movement, though largely engineered by Jews and crypto-Jews, was strongly nationalist, and that they were bent upon a policy of forcible Turkification. The disillusionment of the subject population led to a recrudescence of the old troubles. Incidents on the Montenegrin frontier in Aug. 1912 led to the withdrawal of the Turkish mission, and these were followed by fresh massacres at Berane, whilst similar incidents took place in Macedonia. A formal alliance was entered into between Serbia and Bulgaria, and agreements for common action were made with Greece and Montenegro also. The demands of the Balkan League were rejected by the Turks, and on Oct. 8, anticipating its allies by 9 days, Montenegro declared war against Turkey.

Although the principal objective of Montenegro was Scutari, a large portion of the Montenegrin forces was directed upon the Sanjak and Kossovo, apparently with the idea of staking out claims for the future settlement. The Montenegrins entered Pech and Dyakovitsa, but were forestalled at Prizren by the Serbs. In the meantime they were unable to make any serious impression on Scutari, in the siege of which their lack of scientific military training and modern equipment became manifest. The offer of help from Serbia, at first refused from considerations of *amour propre*, was subsequently accepted, and a Serb general took charge of the operations with a reinforcement of troops and especially of artillery.

During the abortive negotiations in London which followed the armistice entered into at Chatalja, Dec. 9 1912, and the renewed war which ensued on its expiration on Feb. 3 1913, the Great Powers had had under consideration the future of Scutari, which they decided to allot to the newly formed principality of Albania, and on April 4, four days after the Porte had accepted the terms laid down by the Powers in return for their mediation, an allied squadron appeared off the Montenegrin coast. The siege continued, however, to be pressed, and, on April 22, the town was surrendered by its commander, the Albanian Essad Pasha, but, on the renewed pressure of the Powers, the Government announced its evacuation on May 5.

On the outbreak of the second Balkan War, Montenegro assisted Serbia and took part in the Peace of Bucharest, Aug. 6. Though Montenegro had gained a notable accession of territory, the outcome of the war was disappointing for both the country and the dynasty. The Montenegrins had failed to retain Scutari, and the sacrifices suffered in its siege had gone for nothing. The dynasty had also greatly suffered in prestige. Complaints were made that the sons of King Nicholas had frequently absented themselves from the army, especially during the severe winter months, and they were compared unfavourably with Alexander, the Prince Royal of Serbia. The troops, too, who had served with the Serbian army, contrasted the organization and equipment of the latter with their own, and realized to an increasing degree that material self-interest, no less than Pan-Serb patriotism, demanded some form of union with the sister State, and the country generally saw that it was too poor and small to develop in isolation. The reputation of Serbia among the Southern Slavs had vastly increased, and on it were centred all hopes of national reunion; the figure of King Peter had grown notably greater, that of King Nicholas smaller. During the early part of 1914 negotiations were entered into with Serbia for a military, diplomatic and economic union between the two kingdoms, but their conclusion was anticipated by the outbreak of the World War.

In the World War Montenegro threw in her lot with the Entente, and her troops coöperated with the Serbian army. At the instance of the Russian Tsar, the Serbian General Yankovich was sent to Cettigne to assume the functions of chief of the staff, a post in which he was subsequently succeeded by Colonel Pesich. The presence of these officers did not, however, prevent King Nicholas from issuing executive commands on his own authority; the Serbian and Montenegrin forces were never combined under one control, and *liaison* was maintained by the presence at Montenegrin headquarters of a delegate from the Serbian High Command. Austria's main strength was directed elsewhere, and she contented herself in the early stages of the campaign with a defensive attitude on the Montenegrin front.

In the early part of 1915 the Montenegrin court engaged in an intrigue with the Austrians, with whom, prior to the war, King Nicholas had long entertained secret relations. In May of that year, Prince Peter, the youngest son of the King and commander of the important Lovchen position, which overlooked Cattaro and protected Cettigne, had a secret meeting at Budua with the Austrian Colonel Hupka, a former military attaché at the Austrian legation; and in July the Crown Prince Danilo proceeded to Italy, via Athens, where he was alleged to have discussed a separate peace with a German agent.

In October the combined Austro-German-Bulgar attack was launched against Serbia, and the bulk of the Serbian army was eventually forced to retreat through Albania to the Adriatic.

The consequences of the Serbian disaster to Montenegro were aggravated by treachery. In the beginning of Jan. 1916 Prince Peter withdrew his troops from one of the key positions of Mont Lovchen, which fell into the hands of the Austrians practically without a struggle. On Jan. 13 King Nicholas addressed a telegram to the Austrian Emperor asking for terms of peace, although his advisers had unanimously expressed themselves in favour of continuing the struggle, and it was only the uncompromising conditions laid down that eventually led him, on Jan. 19, to flee, first to Medua and thence to Italy. In the meantime the Montenegrin army was entrapped, for the King had refused the advice that he should follow the example of the Serbians and withdraw his army with the latter, and had given orders that it should remain in the country. It thus fell into the hands of the Austrians. Prince Mirko, the King's second son, also remained behind, and subsequently went to Vienna. The object of these manœuvres was evidently to assure the future of the dynasty in any event, for Mirko, since his elder brother was childless, was the eventual heir to the throne.

Intrigues were set on foot for the formation of a Southern Slav vassal State under the suzerainty of the Habsburgs with Mirko as ruler, the State to consist of the débris of Serbia and Montenegro. Mirko himself subsequently died in the Austrian capital. The King retired to France, where he established himself successively at Lyons, Bordeaux, and Neuilly, the three Western Powers according him a subsidy. In May 1916 M. Andrew Radovich, an old opponent, was appointed Premier and in the summer the King received not unfavourably a memorandum advocating a union between Montenegro and the other Southern Slav provinces. A visit to Italy in the autumn resulted in a change of attitude, for official Italy was by no means enamoured of a project which would strengthen the trans-Adriatic kingdom and deprive herself of a useful lever. Henceforward the gap between the dynasty and national feeling steadily widened. In Jan. the Ministry resigned after presenting a series of strongly worded memoranda on the question of national union and on the responsibility of the King for the position in which the country was involved. The appointment

of General Martinovich as Premier only served to bring out the strength of the movement for unity, for the new Ministry also resigned in June after presenting a memorandum of similar tendency to those mentioned above.

The breach between the King and those entitled to speak on behalf of his people was now complete; a Montenegrin committee for national union was formed in Switzerland, and representatives were appointed for the meeting at Corfu, which resulted in the Declaration of Corfu, July 20 1917, by which the delegates of all sections of the Serbs, Croats, and Slovenes agreed upon the establishment of a single kingdom under the sceptre of the Karageorgevich. The entry of the Allied troops into Montenegro after the defeat of the Austro-Bulgars was followed by steps to bring the resolutions of Corfu into effect. Elections were held for a "Great National Assembly" which, on Nov. 26 1918, proclaimed the deposition of King Nicholas and union with Serbia, the resolutions being confirmed at a popular mass-meeting convened at Cettigne by five former Prime Ministers. Allegations of coercion on the part of Serbian troops in the elections were negatived by an Allied commission under General Franchet d'Espérey, and the report of the subsequent investigation carried out by Count de Salis on behalf of the Supreme Council of the Allies was stated by the British Government to bear testimony to the fact that the Assembly represented national feeling. Some disorders broke out in consequence of the incursion of armed bands acting on behalf of Nicholas, and financed and organized in Italy, but, the number of Serbian troops in the country being very small, these bands were forced to retire by the Montenegrins themselves, the defence of its borders being purposely left to a Montenegrin militia.

The general elections to the Serb-Croat-Slovene Constituent Assembly were held on Nov. 28 1920, and in Montenegro resulted in the election of none but advocates of national union. These elections were observed on behalf of the British Government by Mr. Roland Bryce, who reported that they were held under conditions of scrupulous fairness, without coercion on the part of the administration of the triune kingdom, and that they represented the will of the people. The subsidies paid to, and the diplomatic recognition of, the "Government" of ex-King Nicholas were withdrawn by England and France, but Nicholas was still able to maintain a force of adherents at Gaeta, in Italy.

The ex-King died at Antibes March 1 1921, and his entourage proclaimed the Crown Prince Danilo as King, but after six days the latter abdicated in favour of his nephew Michael, son of Prince Mirko, on the ground that his abstention from taking an active part in the war and his German marriage (with Duchess Jutta of Mecklenburg) made him *persona non grata* to the Allies. With the elections to the Constituent Assembly, however, the withdrawal of diplomatic recognition by Britain and France, and the disbanding in June 1921 of the "Montenegrin Legion" which the Italian Government had maintained hitherto at Gaeta, the "Montenegrin question" was virtually closed; it had, in fact, only been kept open latterly as a means of bringing pressure to bear upon the Southern Slav Government in connexion with the Adriatic question, and, in spite of the saying "pays balkanique pays volcanique," the union of Montenegro with its sister provinces seemed likely to endure. Thus the five centuries of struggle for independence and for the Serbian idea carried on by the "falcons" of the Black Mountain found its consummation in a realm as wide as, and more national than, the empire of Tsar Dushan.

Denis, *La Grande Serbie; The New Europe* (weekly), various numbers; White Papers, Cmd. 1123, 1124; A. Radovich, and others, *The Question of Montenegro.* (A. H. E. T.)

**MONTERO RIOS, EUGENIO** (1832–1914), Spanish politician, was born at Santiago de Compostela, Corunna, Nov. 13 1832. He had a distinguished career at the university of Santiago. He was elected to the chair of ecclesiastical discipline at the university of Oviedo, was transferred to a similar chair at Santiago, and thence passed to the chair of canonical law at the Central University, Madrid. His political career began with the foundation in Santiago of *La Opinión Publica*, a journal designed to reunite the scattered Progressist party. In 1869 he was elected deputy (Progressist) and showed himself in the Chamber a strong opponent of ultramontanism and a defender of democratic monarchy. He was Under-Secretary of the Ministry of Grace and Justice in Zorrilla's administration and became the minister under Prim's, and whilst in office was instrumental in introducing civil marriage. Throughout the revolutionary period Montero was the object of bitter attacks by the clerical parties. He continued to hold office during the short reign of Amadeo I. and drew up that King's act of abdication, but held aloof from politics for some years after the accession of Alphonso XII., occupying himself in legal studies. In 1872 he had been made a member of a commission for codifying criminal law, and later in life (1898) he was president of a section of the General Codification commission. In 1888 he was for a short time president of the Supreme Tribunal. Having held office in Herrera's Cabinet (1883) and Sagasta's (1885 and 1892–3), he became a member of the Senate in 1893 and its president 1894–5. He was chief of the Spanish delegation which negotiated the Treaty of Paris with the U.S. at the close of the Spanish-American War of 1898, being also in 1899 again president of the Senate. Throughout his political career he was regarded as one of the leading men in the Liberal party; from 1903 to 1906 he was its chief, and for a few months in 1905 he was prime minister. From 1909 until his death in 1914 he was again president of the Senate. He died at Madrid May 12 1914.

**MONTESSORI SYSTEM.**—In connexion with the theory of education, one of the chief points of new interest during 1910–21 was the attention aroused by Dr. Maria Montessori's work. It is hardly too much to say that, since Froebel, no such stimulus has been given to a revolution in the elements of educational method as her success, from 1907 onwards, with the *Case dei Bambini* in Rome; and the Montessori system has given a new direction to ideas upon child education.

Maria Montessori (b. 1870) came to the study of educational theory after a thorough training in practical medicine. She was the first woman to whom (in 1894) the university of Rome gave the degree of M.D., and as assistant doctor in the "psychiatry" clinic at the university she had become specially interested in the question of the treatment of the feeble-minded. At the Pedagogic Congress at Turin in 1898 she gave an address on this subject, which led the Italian Minister of Education, Signor Barcelli, to ask her to give a series of lectures to teachers in Rome; the result was the foundation of a new school for feeble-minded children, the Scuola Ortofrenica, of which she was made directress. Her ideas as to the proper way of awakening a defective intelligence had been founded on a study of what Dr. Itard, physician to the Institution for the Deaf and Dumb in Paris, had attempted early in the 19th century in the case of the much-discussed "Wild Boy of Aveyron," and particularly of the later work of Edouard Séguin (1812–88), author of the *Traitement des idiots* (1846), who opened in 1839 the first school for idiots in France, and who in 1850 made his home in America and there did so much for the education of defective children. In carrying on Séguin's principles at the Scuola Ortofrenica for the two years that she was directress, Dr. Montessori had such remarkable success that it was borne in upon her that something must be wrong with the methods of education ordinarily applied to normal children. Idiots sent to her from the asylums were being taught to read and write so that they passed just as good examinations as pupils of the same age in the public schools; and, as she says, "while everyone was admiring the progress of my idiots, I was wondering what could keep the normal children on so low a plane." The reason, in her opinion, was clear; the children from the asylums, under her treatment, had been helped in their psychic development, while the normal children, taught by ordinary methods, were retarded. If the same methods were applied to good material that were successful with bad, much better results ought to be attainable; and she determined to investigate the whole subject afresh.

In 1900 she left the Scuola Ortofrenica, and turned her attention definitely away from the question of the feeble-minded to that of the normal child mind and its development. She returned to the university of Rome as a student of philosophy, and devoted herself to experimental psychology, then in its infancy at the Italian universities, at the same time making a prolonged and careful study of the actual practice of teaching at the primary schools. The result of several years of child study and practical pedagogy was to establish her conviction that the master principle in any proper system is "self-education"—that the work of mental growth must be done by the child itself, according to its own initiative and inclination, not in mechanical obedience to dogmatic dictation from a teacher; and she set herself to devise new methods for making the child-mind shape its own channels instead of the teacher telling the pupil what to do.

After six or seven years of inquiry and study a unique opportunity arose in Rome for putting her theories into practice. During the building "boom" at the end of the 1880's, a whole new quarter of apartment houses had been run up by speculators outside the Porta San Lorenzo. It was from the first a complete fiasco, the houses failing altogether to attract the superior class of tenants for which they were intended; and the district gradually developed into the worst of slums, the flats being farmed out room by room to the poorest families, so that at last a serious condition of insanitary overcrowding had resulted, which seriously engaged the attention of social reformers. In order to remedy this evil, an association was started on philanthropic lines, the Instituto Romano di Bene Stabili, with Signor Edoardo Talamo as director-general. It bought up a large part of the San Lorenzo quarter, and reorganized it in 1906 in separate and convenient working-class tenements, with proper air-space, prizes being instituted for the best-kept dwellings. A novel point of the scheme was the provision of infant schools (*Case dei Bambini*) for the children of each block, the supervision of which was entrusted to Dr. Montessori, the first of these being opened in Jan. 1907. These "houses of childhood" for children between three and seven were themselves a very interesting social experiment apart from the new methods of teaching which Dr. Montessori introduced. They provided a crêche and something more, taking the children off their mothers' hands during working hours. Each school had a directress living in the block which it served and in touch with the parents, who could at any time come and see how the children were getting on; it was thus part of the home life.

The Montessori system of education was first put in practice in these tenement schools, under teachers following Dr. Montessori's methods. Its fundamental aim and object is self-education by the pupils themselves. There are no time-tables, no set lessons, no classes. There are no rewards or punishments of the ordinary kind. The pleasure of succeeding and getting things right is the only incentive. "Each child is doing what, for the time being, pleases him best. When he is admitted to the school he sees small groups of children playing at various 'games,' and he joins the group which happens to take his fancy. Then and there his education begins. All kinds of interesting 'occupations' are going on, and wherever he goes he will get help and guidance from the teachers. If he gets tired of playing at this thing he goes off and plays at that. But he is never idle, for whatever he does interests him. The children are provided with light and comfortable chairs, which are easily moved about. There are also rugs laid on the floor for them to sit, kneel or recline upon, should they prefer those attitudes. Low and light tables are provided in abundance, but there is also plenty of open floor-space, and many of the 'occupations' are carried on on the floor" (Holmes). An extensive variety of apparatus, elaborately devised by Dr. Montessori, is provided for the educational games by which the children are stimulated to acquire knowledge; and this "didactic material" constitutes a distinctive part of the originality of the system.

The first stage is to develop the senses of touch, sight and hearing; this is done both by games of various sorts and by guiding the attention systematically to the association of things, names and ideas. When a child washes his hands, for instance, he is given first cold and then hot water, and led to observe and understand the difference; the distinction of rough and smooth is emphasized by the provision of different qualities of cards for fingering and sorting. In each case the teacher gets the child to know the word, "hot," "cold," "rough," "smooth," and thus the knowledge of language is extended in all directions ("high," "low," "thick," "thin," "round," "oval," etc.) before any question of writing or reading arises. Ideas of form and colour are given precision by games with blocks, cylinders, etc., of varying sizes, to be fitted into frames, or with shades of silk to be arranged to match; touch is practised by playing the games blindfold; the sense of hearing is developed by the "silence" lesson, and by the use of small cylindrical boxes containing stones, sands and different substances to be rattled by the children, who arrange them in order of intensity of sound and so forth. Skill and neatness in the use of the fingers and movement of limbs are stimulated partly by the mobility of the light furniture, which the children learn to rearrange for their own comfort, and partly by games at tying and untying, hooks and eyes, dressing and undressing, waiting on one another at table, washing up, and so on. Many of these occupations are preliminary to writing and reading, and lead naturally up to both.

Writing comes essentially before reading, on the Montessori system, in any proper sense of "reading." Emery-paper letters gummed on cards are provided, with which the child is familiarized by games of hide and seek, etc., so that, without any active teaching of the alphabet, he not only knows them by sight and by name, but also by feeling. He learns how to imitate them, partly by a touch game of passing the fingers over the paper letter, thus making the actual motion of writing, and partly by playing at pencilling and colouring with specially devised cards on which an outline is given. The child thus learns to write before he knows that "writing" is what he is learning; the sounds and shapes of the letter being known it is a natural transition to build up the letters and their sounds into words.

The next thing is for the child to "read"—not merely to re-translate into sound a word he has translated into symbol, which goes with the acquisition of "writing," but to extract a previously unknown idea from written or printed symbols of the same sort not put together by himself. It is found, however, that, at any rate in so easy and phonetically spelt a language as Italian, this is very quickly learnt. Numbers of words, already well known to the children, are written on cards, and various games are played in identifying them with their objects; and from single words the children pass to phrases and sentences, the teacher writing on the blackboard, for instance, questions or orders which form part of a game. Arithmetic is similarly introduced to the children's minds by the employment of counting games, in which an apparatus of striped poles, counters, etc., is used. The whole curriculum is devised for the content and happy employment of the natural energies of the child, who is left free to respond to his own impulses, under the influence of "didactic material," rather than under the discipline of a teacher.

After 1912 the diffusion of Dr. Montessori's educational influence was rapid and widespread. Following close upon the interest which had already been aroused in Italy and America, Dr. Montessori, in response to urgent requests from educational enthusiasts all over the world, began a series of international training courses for teachers. These courses were held in Rome in 1913 and 1914. In subsequent years Dr. Montessori held training courses in Barcelona and in several cities of the United States, two international courses having been held in London in 1919 and 1921. To these training courses came not only class teachers of the particular country, but persons eminent in the educational field from all over the world. During this later period two of the most notable features in connexion with the Montessori movement were the appearance of Dr. Montessori's new books, *The Advanced Montessori Method* and *The Didactic Material for the Education of Children from 7 to 11 years*. The first volume gives a clear and complete exposition of the scientific researches which led to the establishment of the fundamental psychological and physiological principles upon which Dr.

Montessori bases her method of auto-education, and the second volume fully describes in detail the educational material for the older children. The form of the advanced apparatus is such that the children who have passed beyond infant school age are provided with material which continues to perfect the muscular control achieved in a previous stage, while at the same time the way in which the material is used tends to strengthen those attributes of character which are the tests of educational values. By means of the objects provided for the child between the ages of 7 and 11 he becomes possessed of considerable mental acquirements, notably in the comprehensive intellectual fields of mathematics and language. The arrangements of artistically coloured beads which are used by the child for his progress in arithmetic, the ingenious geometrical forms which render geometry no longer a tedious abstraction, but a fascinating reality, the system of small attractive cards handled by the children in their study of grammar, all form a far more potent incentive to work and persistent effort than any exhortation or command of the teacher.

" Montessori Societies " have, since 1912, come into existence in London, New York, and elsewhere, for dissemination of the ideas of the system and promoting its training courses.

The Special Report (1912) by Mr. E. G. A. Holmes to the Board of Education in England contains a critical examination of the Montessori methods. See also Dr. Montessori's first book on *The Montessori Method* (Eng. trans. by Anne E. George, 1912), in addition to her later books mentioned above. (H. CH.)

**MONTREAL** (*see* 18.790), the commercial metropolis and the largest city of the Dominion of Canada, had a pop. in the autumn of 1920 estimated at 802,000. The local trading area, including adjoining towns on the island of Montreal and those settlements on the mainland which lie immediately opposite the city, contained in 1920 a pop. of 1,100,000. The port of Montreal is the second largest in America, being surpassed only by New York. Over 25% of Canada's export trade passes through Montreal. The harbour has eight m. of deep water (25–35 ft.) and wharfage with berths for 125 vessels on a 10 m. front. In 1921 a costly scheme for the further improvement of the harbour, including the electrification of the entire water-front, was under way. In 1919 8,280 vessels with a total tonnage of 6,537,014 entered the port. Merchandise to the value of $353,138,249 was exported, and imports amounted to $246,898,626 in the same period. The largest flour-mill in the British Empire, with a capacity of 6,000 bbl. in 24 hours, is located here. The bank clearings amounted in 1920 to $7,109,189,038, the highest in Canada. Taxable property was valued in 1918 at $623,820,958, and property exempt from taxation at $226,934,131. The Montreal Chambers of Commerce had 3,500 members in 1920. Montreal is far ahead of other Canadian cities in the use of electric power in industry.

The form of municipal government underwent several alterations in the decade following 1911, and eventually the control of municipal affairs was placed in the hands of an administrative commission of four, appointed by the Provincial Government.

The construction of a tunnel under Mt. Royal and the centre of the city by the Canadian Northern Railway Co. was an important engineering feat completed in 1918. The company built an imposing new terminal station in the centre of the city at the tunnel head, supplanting its old Moreau Street station. Electric trains running through the tunnel to the north-western side of Mt. Royal caused the growth of a new suburb on that side of the mountain.

Important educational buildings erected since 1911 include the McGill Medical Building, a magnificent structure that replaced the building destroyed by fire in 1907, the Macdonald Engineering Building of McGill University, a large and finely equipped technical school in connexion with Laval University, a new high school erected by the Protestant Board of School Commissioners, and a fine pile of buildings to house Loyola College, a Jesuit school of high standing.

McGill University, benefiting by gifts from its great benefactor, Sir William Macdonald, was able to develop further its faculty of music, to found new degrees in law, commerce and household science, and to further extend some of its departments. A school of physical training was opened in connexion with the university, and a department of social service was inaugurated. The McGill Stadium, one of the finest athletic amphitheatres in North America, was opened in 1918. After the death of Sir William Macdonald in 1919 provision was made for the further endowment of Macdonald College at Ste. Anne de Bellevue, the faculty of agriculture of McGill. Sir William Peterson, the principal of McGill for many years, retired in 1919 owing to ill-health. Under his guidance the university had risen from a local institution to one of the foremost seats of learning in the British Empire. His influence was a chief factor in McGill's war effort, which included the extension of the old Officers' Training Corps, and the raising of a number of infantry companies, an artillery unit, etc. He died in London in 1920, his successor (after Sir Auckland Geddes, who had originally accepted the position, had been appointed British ambassador in Washington) being Sir Arthur Currie, commander-in-chief of the Canadian forces in the World War. A campaign to raise $5,000,000 for the university was organized and carried successfully to completion in the summer of 1920.

The administrative buildings of the Montreal branch of Laval University were destroyed by a disastrous fire in the autumn of 1919. A movement that had been gaining strength for some years to separate the Montreal branch from Laval University at Quebec, now found culmination, and the university of Montreal was founded, the buildings of the old branch of Laval being taken over by the new institution. A number of new courses were added, including social and political science, and the faculty of applied science was further developed. Considerably over $3,000,000 was raised by public subscription as a building fund, and in 1921 negotiations were under way for securing land for new administrative buildings, etc.

The growth of the Jewish pop. of Montreal during the 15 years preceding 1921 has been a notable feature. In 1920 there were estimated to be about 75,000 Jews in the city. A scheme for the foundation of a Jewish university was under consideration.

**MONYPENNY, WILLIAM FLAVELLE** (1866–1912), British journalist, was born in Ulster Aug. 7 1866. Educated at Trinity College, Dublin, and Balliol College, Oxford, in 1893 he joined the editorial staff of *The Times*, and early in 1899 became editor of the Johannesburg *Star* in the Transvaal. He played a useful part, as a publicist, on the side of the Reform party there, and when war came he joined the Imperial Light Horse and was one of the defenders of Ladysmith. Returning afterwards to his position on the *Star*, he did much to promote Lord Milner's work of reconstruction, but resigned in 1903 owing to his hostility to the introduction of Chinese labour into the mines. He was then entrusted by *The Times* with the task of writing the official biography of Disraeli, and also did other work for that paper, becoming in 1908 a director of the company. Owing to ill-health the first volume of the *Life of Beaconsfield* (ultimately extending to six volumes) did not appear until 1910, and the second shortly before his death. It was completed by Mr. G. E. Buckle, formerly editor of *The Times*. Monypenny died in the New Forest Nov. 23 1912.

**MOODY, WILLIAM VAUGHN** (1869–1910), American poet and playwright, was born at Spencer, Ind., July 8 1869. He was educated at Harvard (A.B. 1893; A.M. 1894) and was assistant in English there 1894–5. From 1895 to 1907 he was at the university of Chicago as instructor and, after 1901, as assistant professor. He died at Colorado Springs Oct. 17 1910. He was the author of *The Masque of Judgment* (1900); *Poems* (1901); *The Fire-Bringer* (1904, intended as the first member of a trilogy on the Promethean theme, of which *The Masque of Judgment*, already published, was the second member); *The Great Divide* (1907) and *The Faith Healer* (1909). Of these the last two were prose dramas and were very successful on the stage, especially the first. He compiled (with Robert M. Lovett) *A First View of English and American Literature* (1902), and edited *The Complete Poetical Works of John Milton* (1899, Cambridge ed.) and (with George Cabot Lodge and John Ellerton Lodge) *The Poems of Trumbull Stickney* (1905).

His complete works, including *The Death of Eve*, a fragment of the third member of the proposed trilogy mentioned above, were edited with an admirable introduction by Prof. John M. Manly (1912).

See also Daniel Gregory Mason, *Some Letters of William Vaughn Moody* (1913).

**MOORE, GEORGE** (1853– ), Irish writer (*see* 18.808), broke fresh ground in 1916 with *The Brook Kerith*, a work of fiction based on the Gospel story. He had professedly taken leave of literature in three remarkable volumes of quasi-reminiscences, entitled *Ave* (1911), *Salve* (1912) and *Vale* (1914). Later he produced two privately printed volumes-de-luxe, *Avowals* (1918) and *A Story Teller's Holiday* (1920), and retold the story of *Abélard and Héloïse* (1921).

**MOORE, THOMAS STURGE** (1870– ), English poet, art critic and engraver, was born at Hastings, Sussex, March 4 1870.

He published the *Vinedresser and other Poems* (1899); *Aphrodite against Artemis* (1901); *Absalom*, a play (1903); *The Little School* (1905, enlarged edition 1917); *Marianne* (1911); *The Sea is Kind* (1914); and other collections of poetry, as well as prose studies of Altdorfer, Dürer, Correggio and others, and several volumes of essays, *Art and Life* (1910); *Hark to these Three* (1915); *Some Soldier Poets* (1919); etc. In 1920 he published two new poems *Danaë* and *Aforetime*, and a prose idyll *Blind Thamyris*.

**MOORHOUSE JAMES** (1826–1915), English divine, was born at Sheffield Nov. 19 1826. He was educated at St. John's College, Cambridge, where he graduated in 1853. He was ordained the same year, and made a reputation as an eloquent preacher, which brought him to the notice of Queen Victoria. He was made chaplain-in-ordinary to the Queen and a prebendary of St. Paul's in 1874, and in 1876 went to Australia as Bishop of Melbourne. In 1886 he was recalled to England to become Bishop of Manchester. He retired in 1903, and died at Poundisford Park, near Taunton, April 9 1915.

See Edith C. Rickards, *Bishop Moorhouse* (1920).

**MORANT, SIR ROBERT LAURIE** (1863–1920), English civil servant, was born at Hampstead April 7 1863. He was educated at Winchester and New College, Oxford, and on leaving the university was for a few years a schoolmaster. Later he went to Siam as educational adviser, and was entrusted by King Chulalongkorn with the drawing up of a scheme of education for the whole country. In a few years he returned to England, and after some experience of social work in the East End of London was appointed in 1895 to assist in the direction of the Office of Special Inquiries and Reports in the Board of Education. His first noteworthy piece of work was a report on the condition of the French primary schools. He became private secretary to successive ministers, and on him devolved a great deal of the preparation of Mr. Balfour's Education Act of 1902. In 1903 he was appointed permanent secretary of the Board of Education. In this capacity he proved himself a most efficient administrator, and in 1907 he was created K.C.B. In 1912, on the introduction of the National Insurance bill, Morant was appointed chairman of the Insurance Commission, a position which led naturally to his appointment as secretary to the Ministry of Health on its formation in 1919. He died in London after a few days' illness March 13 1920.

**MORET Y PRENDERGAST, SEGISMUNDO** (1838–1913), Spanish politician, was born at Cadiz June 2 1838. He was educated at the Central University, Madrid, and became professor of political economy, continuing at the same time his studies in jurisprudence. In 1863 he was elected Liberal deputy for Almaden and took part in the revolution of 1868, afterwards representing Ciudad Real in the Constituent Assembly of 1869 and becoming noted for his eloquence. He took office under Gen. Prim in 1870 first as Colonial Secretary and later as Finance Minister. He was for a few months in 1872 Spanish ambassador to Great Britain, and after resigning this post accepted the directorship of a large London bank. A year later he returned to Spain. He was again elected deputy for Ciudad Real in 1879, rallied to the monarchy in 1882, represented Orgaz from 1886 to 1890, was Minister for Foreign Affairs under Sagasta in 1885 and again in 1893–4, Minister of the Interior 1885–8, and Minister of Colonies 1897. In this capacity he advocated the grant of autonomy to Cuba and Porto Rico, and he was opposed to the war with America of 1898. He rose to be head of the Liberal party and became Prime Minister in 1905, but fell in 1906, though he was called back to office for an ephemeral spell of three days in that year and again in 1909 for a few months. Failing to keep together his unruly hosts he took refuge in the post of president of the Chamber, in which office he died at Madrid Jan. 28 1913.

**MORGAN, JOHN PIERPONT** (1837–1913), American financier and banker (*see* 18.834), died in Rome March 31 1913. In Jan. 1913 he sailed from New York for Egypt, where he became seriously ill. He was carried to Italy but never recovered. His will provided that after the distribution of enumerated bequests amounting to about $17,000,000, chiefly to his family, the residue of his estate should pass to his son, John Pierpont Morgan, Jun. (see below). In 1916 the estate was finally appraised at $69,499,732. He left only some $700,000 to charities; but while living he had been a generous giver, and in his will suggested that his son continue certain accustomed annual contributions. His works of art and books were left to his son without restrictions, although in his will he said, "It has been my desire and intention to make some suitable disposition of them or of such portion of them as I might determine, which would render them permanently available for the instruction and pleasure of the American people." In the summer of 1913 most of the art collection was placed as a loan exhibit in the Metropolitan Museum of Art, New York. Later some items, mostly replaceable, were sold. The remainder, consisting of over 3,000 pieces, was presented to the museum by the son in Dec. 1917, and a new wing was added to the building to house them permanently (opened June 1918). This collection covers all periods and includes matchless bronzes, enamels, porcelains and tapestries. The library, retained by the son, was appraised at $7,500,000. It consisted of more than 20,000 volumes of illuminated manuscripts, early printed books, examples from famous presses and association copies.

His son, JOHN PIERPONT MORGAN (1867– ), American financier, was born at Irvington, N.Y., Sept. 7 1867. On graduating from Harvard in 1889 he entered the banking house of Morgan, Grenfell & Co. (the London branch of J. P. Morgan & Co.) and 12 years later joined his father in New York. When Congress in 1902 authorized the President to purchase the rights of the old Panama Canal Co. for $40,000,000 in gold, Mr. Morgan arranged for the payment (1904). On the death of his father in 1913 he inherited the greater part of his estate and became the head of the firm. On the outbreak of the World War he arranged the first credit, $12,000,000 for Russia. In 1915 his firm was appointed agent in the U.S. for the British Government; and until after America entered the war, was also purchasing agent, receiving a commission of 1% on all purchases. In April his firm provided a loan of $50,000,000 for the French Government; in Sept. it organized a syndicate for floating the Anglo-French loan of $500,000,000 and followed this with other large loans, especially for the British Government. In July he was shot, but not dangerously wounded, in his home by a crazed German sympathizer, who declared that he was trying to force Mr. Morgan to bring about an embargo on arms. From 1914 to 1919 he was a member of the Advisory Council for the Federal Reserve Bank in New York. In 1919 he was for a time chairman of the International Committee, composed of American, British and French bankers, for the protection of the holders of Mexican securities. In Nov. of the same year he was made a director of the Foreign Finance Corp., organized to engage in the investment of funds chiefly in foreign enterprises. In May 1920 President Wilson transmitted to Congress a letter written long before, in which Mr. Morgan offered to give his London home as headquarters of the American embassy there; but it was not until 1921 that Congress accepted the gift. He was a director in numerous corporations, including the U.S. Steel Corp., the Pullman Co., the Aetna Insurance Co., and the Northern Pacific Railway Co.

**MORLEY** (OF BLACKBURN), **JOHN MORLEY,** VISCOUNT (1838– ), English statesman and author (*see* 18.840), continued to hold the seals of the India Office till Nov. 1910, when he resigned them, as he himself revealed subsequently, "partly because I was tired, partly from a feeling that a new viceroy would have fairer openings with a new secretary of state; partly, too, that I might have a farewell chance of literary self-collection." One of his last important official acts had been to resist the appointment of Lord Kitchener to the viceroyalty, pressed strongly upon him by King Edward just before his death. He remained in the Ministry as Lord President, and was one of the four counsellors of state to administer the kingdom during King George's visit to India for the Delhi Durbar in the winter

of 1911–2. In the critical period of domestic politics which began with the budget of 1909 he played a somewhat prominent part. He defended Mr. Lloyd George's budget in the great debate of Nov. 1909, and, while admitting that the Lords had the legal right of rejection, said that to assert it was "a gambler's throw." He poured cold water on proposals like Lord Rosebery's for House of Lords reform, and like Lord Lansdowne's for a referendum; and gave warm support to the Parliament bill, which would repair the national machinery. Owing to the temporary failure of Lord Crewe's health, Lord Morley led the House of Lords during most of the Session of 1911, in which that bill was passed; and it was he who read out to the House on the last night of debate the definite assurance from King George which finally secured the exiguous but adequate majority of 17: "His Majesty would assent to a creation of peers sufficient in number to guard against any possible combination of the different parties in opposition by which the Parliament bill might be exposed a second time to defeat." He not only took charge of the India Office during Lord Crewe's illness, and of the Foreign Office in Sir Edward Grey's short holidays, but he was an outstanding figure in the Home Rule debates of 1913 and 1914. In moving the second reading of the Amending bill on July 1 1914, he said that the National Volunteers had dispelled the illusion that the masses of the South and West of Ireland had lost their care for Home Rule; the danger was lest the constitutional agitation for self-government might give place to older methods of violence and disloyalty.

The outbreak of the World War brought Lord Morley's official career to an abrupt termination. He made no public explanation of his reasons for resigning, but withdrew to the retirement of his Wimbledon villa, where he occupied himself with writing two most interesting volumes of *Recollections*, which were warmly welcomed on their publication in 1917. In the introduction he said: "The war and our action in it led to my retirement from public office. The world is travelling under formidable omens into a new era, very unlike the times in which my lot was cast. . . . The world's black catastrophe in your new age is hardly a proved and shining victory over the principles and policies of the age before it." In 1921 his publishers brought out a complete edition of his works in a handsome *format*.

**MOROCCO** (*see* 18.850).—The year 1911 was rendered memorable in Morocco by the Agadir crisis. Mulai Hafid had become unpopular through his dependence on the French and the exactions of his grand vizir, El Glawi. There was a general rising of the tribes round Fez in Oct. 1910. Meknes (Mequinez) was captured, and Fez itself besieged in March 1911. French troops were sent in April, and again in May, to occupy the city and pacify the district. El Glawi was dismissed. This French occupation of Fez, though the need for it had been duly notified to the Powers, was resented by Spain and Germany. The former countered it by the sudden occupation (June) of El Qasr and Laraish (El 'Araish). The German Government on July 1 1911 announced to the French Minister for Foreign Affairs its decision to send a gunboat to Agadir, and dispatched the "Panther" forthwith. The alleged motive was to safeguard German subjects and property against disturbances in the Sus; the real one was to challenge the extension of French influence in Morocco as contrary to the Agreements of 1906 and 1909. The situation became extremely critical, and for a time it seemed as if war were inevitable. The protests of France were unavailing until Great Britain declared her intention of standing by the Entente, and her formal objection to Germany's obtaining territorial influence in Morocco. A series of diplomatic "conversations" resulted in the Franco-German Treaty of Nov. 4 1911, by which France was to cede some of her Congo territory to Germany in return for the recognition by the latter of her political protectorate over Morocco, economic equality being reaffirmed. (The word "protectorate" was [illegible] in the actual treaty, but it was in the letters accompanying it.) Spain at first objected, but, through the intervention of Great Britain, a Franco-Spanish treaty was concluded on Nov. 27 1911. This arranged such debated points as customs, the management of the projected Tangier–Fez railway and the appointment of the Sultan's *khalifa* (deputy) at Tetuan. It slightly revised the Franco-Spanish boundaries determined by the Convention of Oct. 3 1904. The boundary of the northern Spanish zone follows the Muluya (Mulwiya) from its mouth to near Meshra el Klila, thence, turning W., it runs immediately N. of the Wad Waghra to Jebel Mulai bu Shta; thence it strikes N.W. to the Wad Lekkus, follows its course and, afterwards, lat. 35° N., to the Atlantic coast. Both banks of the Lekkus and El Qasr and Laraish fall within the Spanish zone. The treaty also recognized the rights of Spain in the S. over the enclave of Ifni, bounded to N. by the Wad bu Sedra, to S. by the Wad Nun, to E. by a line about 15 m. from the coast. The negotiations of 1911–2 between the Powers resulted in the internationalization of the Tangier zone, consisting of Tangier, its environs and the territory of the El Fahs tribe to S. and W. of it—about 100 sq. m. in all. By this understanding Tangier was "to be given a special régime to be agreed upon later." In 1921 Spain maintained that the possession of Tangier was indispensable to her in order to round off her protectorate zone, both from an economic and a territorial point of view. France on her side put forward claims to the town based upon her general position in Morocco and the Mediterranean. Meanwhile the Sultan is sovereign and the town and the harbour are administered by an International Commission.

On March 30 1912 Mulai Hafid signed a treaty with France accepting the protectorate, which was subsequently recognized by the Powers, who withdrew their diplomatic representatives. General Lyautey was appointed resident-general. The protectorate has an office in Paris at 21, Rue des Pyramides.

There were continued risings in the Fez-Sifru district and in the Rif during the autumn of 1911, and Fez was again besieged in March–April 1912, when the Sherifian army mutinied and killed several of their French instructors. In August a new Pretender appeared in the Sus, Hamed el Hiba, son of the notorious religious agitator Ma el 'Ainin, who had died at Tiznit (Oct. 1910). El Hiba occupied Marrakesh (Aug. 1912) but was driven thence in Sept. and fled south. Mulai Hafid abdicated on Aug. 12, appointing his brother, Mulai Yusef, as his successor. Hafid was pensioned by France and lived for a time at Tangier; after the outbreak of the World War both he and 'Abd el 'Aziz resided in Europe. In Oct. Gen. Lyautey occupied Agadir. Fighting in western Morocco continued for some months among the Shiadma, Haha, Zayan and Tadla, the most powerful chiefs being two rival *kaids* of the Haha and Moha u Said of the Tadla. But this district and that round Fez were pacified by the spring of 1913, and attention became increasingly centred on eastern Morocco, and the need for securing communications with Algeria by the occupation of the important strategic position of Taza. This was accomplished in May 1914, in the face of much hostility from the local tribes. The following month saw the capture of the scarcely less important fortress of Khenifra in the Zayan country. These two essential positions had barely been secured when the outbreak of the World War necessitated the withdrawal of French regular troops, whereupon ensued the immediate revolt of the powerful Branes, Ghiata, and Beni Waghrain round Taza, and the Zayan in the west. The diminished French forces, however, gallantly held their own, and the great *kaids* of the Atlas and the *bashas* of Tarudant and Tiznit in the S. remained loyal. The latter kept El Hiba's forces in check. With a view to maintaining confidence, public works were continued and exhibitions and fairs were held at Casablanca (1915, 1918), Fez (1916) and Rabat (1917); these were visited by thousands of natives, and created an immense effect.

All through the war German money, arms and military instruction were lavished on the anti-French tribes through German agents harboured in the northern Spanish zone, while arms were repeatedly smuggled through Ifni and Rio de Oro. The attempt of the submarine U20, however, to land 6,000 rifles at the mouth of the Wad Nun (Oct. 1916) was frustrated. Throughout 1915 and 1916 there was fighting along the Wad Waghra.

the chief native leaders being 'Abd es Salam, 'Abd el Malek (grandson of 'Abd el Kader), and Raisuli, while El Hiba came N. to join them. In the Tadla, Moha u Said was simultaneously giving trouble. All these chiefs were in German pay. Military occupation was pushed forward by the French throughout 1916 and 1917, and many important posts established. The advance in the Gigu valley brought about the submission of practically the whole Tafilalt and, with the junction of several French columns on the Upper Muluya, isolated the Ghiata and Beni Waghrain in their mountain fastnesses. In May and June 1917, 'Abd el Malek was driven from Taza and forced to take refuge in the north On March 24, in the Sus, El Hiba's forces had met with a decisive defeat at Wijan, but he continued to receive encouragement from Germany until Oct. 1918. El Hiba died at Kerdus in the following spring, and his forces, under his brother, Merebbi Rebo, were finally dispersed by the *basha* of Tiznit. The Tafilalt was definitely occupied at the end of 1917, and a wireless station and aerodrome established. In Aug. 1918 the all-powerful Ait Atta of the district were stirred to revolt by a *sherif*, Si Moha Nifruten, but the rising was suppressed by April 1919, with the powerful aid of El Glawi, son of the deposed ex-vizir, *basha* of Marrakesh, who in Jan. brought 10,000 men across the High Atlas. (His brother, the Kaid el Glawi, also a loyal ally of France, had died in Aug. 1918.) In the N. intrigues and hostilities, still engineered by Germany, persisted through the early part of 1918.

In the autumn of 1919 the Beni Waghrain were stirred up by a new pretender, and the Seghrushen round Sifru by Sidi Raho. Two risings occurred in the Gharb, in the spring of 1918 and in Oct. 1920. This last was suppressed by the French occupation of the sacred city of Wazzan. Simultaneously the turbulent Ida u Tanan of the S.W. submitted. French rule was thus consolidated in all districts save the Middle Atlas, the Beni Waghrain stronghold.

In 1912 the territory occupied by the French was about 88,000 sq. km., in 1914 163,000 sq. km.; in 1921 France nominally occupied 235,000 sq. km., but exerted effective economic control over about 100,000 sq. km. only.[1]

In the Spanish zone, the lack of roads and the insecurity resulting from the anarchy and brigandage prevalent among the Rif and Jebala tribes retarded development. Fighting continued in both the eastern and western districts. In March 1919 a rising occurred N.E. of Fez, the remains of 'Abd el Malek's movement. In the W., Raisuli as protagonist, while affecting to serve the cause of Spain, and actually, in 1916, receiving arms and money from her, was really seeking to make himself quasi-sultan of N.W. Morocco. In 1916 he entrenched himself at Fonduk 'Ain el Jedida near Tetuan, and was driven thence only in Oct. 1919. The Tangiers–Tetuan road, which he had held, was thus reopened and the Anjera and Wad Ras tribes made their submission. A year later, however, there was fresh fighting with the Beni Huzmer and others, probably directed by Raisuli; Spanish troops from Tetuan then made a somewhat precarious entry (Oct. 14 1920) into the "forbidden city" of Sheshawan, and surrounded it by a ring of military posts. Troops advancing to join them from El Qasr were unable to reach Sheshawan, and had to fall back on their base at Laraish, leaving Raisuli free to operate from his mountain stronghold. In Nov. several attacks were made by the tribes on Spanish patrols and posts in the Tetuan-Sheshawan district, and it seemed at the close of the autumn campaign as if the more remote posts might need to be evacuated.

*Administration and Finance.*—The outlines of the administrative organization in the French zone are to be found in the treaty of March 20 1912. There is on the one hand the *Maghsen* or Sherifian administration, and on the other the French administration of the protectorate. The resident-general has plenary powers; he promulgates the decrees given by the sultan and is the only intermediary between the sultan and foreign Governments. The *Maghsen* includes the grand vizir and the vizirs (ministers)—Justice and Public Worship, the *Habus* (religious endowments) and Domains—the grand vizir being prime minister. Liaison is maintained between the *Maghsen* and the protectorate by the councillor of the Sherifian Government who is director of Sherifian affairs and is at the head of the technical services of control. French administration, under the high authority of the resident-general, is directed by the general secretary of the protectorate. The departments are: General Administration (Civil and Native Affairs), Finance, Economic Services (public works, agriculture, commerce and colonization, posts and telegraphs, etc.), Public Instruction and Public Health. Rabat is the administrative capital.

The French authorities supervise native administration through local *bureaux de renseignements*. In seven of the chief towns the old native council (*Mejlis*) had (1918) been reconstituted, to aid the *basha* in municipal government.

The protectorate at once started to restore the financial position of Morocco by the annual repayment of instalments of the public debt, and careful development of sources of revenue, such as the reformed *tertib* (agricultural tax). In 1919 the revenues were estimated at 102,440,000 francs, the expenditure at slightly less. In 1920 the long-standing difficulty of the double currency, then accentuated by the depreciation of the French franc compared with the Hassani peseta, was solved by the adoption of a local franc currency.

*Population.*—It is now recognized that past estimates of the population of Morocco, based on acquaintance with the more populous coast regions, were excessive; no statistics were obtainable up to 1920 for a great part of the interior, which seems to be very sparsely inhabited. The total native pop. is variously estimated at from 4½ millions to 5,400,000, of whom about 3½ millions live in the French zone. The European pop. (1921) numbered about 100,000, of whom two-thirds were French. Immigration ceased during the World War but in 1919 had begun again and in that year numbered about 10,000 persons, largely at Casablanca. The most densely peopled region is that of the Atlantic coast (Gharb, Huz, etc.). In 1917 the pop. (in round numbers) of 10 principal towns was:—

| | Total | "Total" includes | |
|---|---|---|---|
| | | Europeans | Jews |
| Fez | 105,850 | 850 | 10,000 |
| Marrakesh | 102,000 | 2,000 | 18,000 |
| Casablanca | 97,000 | 38,000 | 10,000 |
| Tangier | 52,000 | 11,700 | 12,000 |
| Tetuan (1919) | 40,000 | 1,000 (& garrison) | 7,250 |
| Rabat | 37,550 | 9,700 | 3,800 |
| Meknes | 36,700 | 1,200 | 5,000 |
| Mazagan | 21,630 | 1,600 | 3,000 |
| Mogador | 19,000 | 600 | 9,500 |
| Ujda | 18,150 | 4,150 | 2,000 |

Saffi had then a pop. of about 20,000; Sallee of 18,000; Melilla, 40,000, of whom 17,700 were soldiers.

*Economic Development.*—Despite the formidable hindrances created by the World War, the settlement and development of the *French Zone* proceeded steadily, the success of this "peaceful penetration" being in large measure due to the genius and popularity of Gen. Lyautey. The immigrants at Casablanca rose from 3,238 in 1911 to 29,755 in 1913; the war then caused a reduction, but in 1918 they numbered 22,140. Well-built European quarters have sprung up near the old towns; the ports have been improved, and a new port, Kenitra, on the Sebu, opened up. At Casablanca 24½ million francs were expended in 1919 in laying out new sites and in building. The amount of capital engaged in development schemes of various kinds was at the end of 1919 35 million francs. Railways have been extended, and a network of roads constructed, on some of which regular services of motor transport run. Anti-malarial and other hygienic measures have been adopted, and medical centres and travelling infirmaries set up; in 1917 these treated over 1,220,800 native patients. Native schools, teaching French, Arabic and Berber, and Jewish schools numbered 21,520 pupils in 1917. Agricultural and industrial enterprises (*e.g.* flour- and flax-milling) have been fostered, and scientific and antiquarian research prosecuted.

Harbour works were (1921) in construction at most of the ports: at Casablanca they included an inner harbour with two quays and a floating dock, and the construction of a great jetty, 2,100 metres in length (of which 1,240 metres were completed by 1921), to form an outer port. Mehediya has been superseded by Kenitra, 10½ m. up river, which, with its extensive river frontage for quays, is the only port where lighters are not required. Its trade rose from 4 million francs in 1914 to 20 million in 1915; in 1917 it equalled that of Saffi and Mogador. A channel has been cut through the bar at the mouth of the Sebu. At Rabat, a cement bridge over the Wad bu Ragrag, to supersede the ferry to Sallee, was inaugurated Jan. 1 1920.

In the *Spanish Zone* irrigation and cultivation have been attempted in the Selwan and Garet regions; the care of forests undertaken; schools and infirmaries established; and a native police force organized at Melilla. Extensive harbour works were (1920) in progress at Ceuta and Laraish. The mines near Melilla have been worked by several companies. Military posts have pushed forward in the Muluya and Wad Kert regions. The expenditure for 1918 (exclusive of the expenses of the military occupation) was nearly 12 million pesetas, a deficit of 8½ million pesetas having to be met by

[1] For the successive stages of the occupation see map in Piquet, *Le Maroc*, 1917.

a subvention from the home Government. In Jan. 1919 Gen. Berenguer was appointed resident-general.

Agriculture is the principal resource of Morocco as a whole and forms the basis of the economic future of the country. The total cultivable area under French control in 1921 was estimated at approximately 25 million ac., of which 5,900,000 ac. were actually under cultivation, 5,200,000 ac. earmarked for reclamation and drainage, 12,355,000 ac. common lands, and 1,235,000 ac. forests. The chief crops are barley, wheat, maize and millet, representing 88% of the total cultivated area; other crops are vegetables, flax, hemp and henna; 124,000 ac. were under orchards and vineyards in 1919. Under proper cultivation western Morocco should become one of the richest cereal-producing areas in the world. Stock-breeding is also important; statistics for 1920 show that live stock comprised: sheep 6,700,000, goats over 2,000,000, cattle 1,300,000, pigs 130,000; while beasts of burden numbered: donkeys 420,000, camels 86,000, horses 65,000, and mules 54,000. The total area of forests in the French zone of Morocco is about 3,706,000 ac.; on the coast a belt of cork-trees covers an area of 338,000 ac.; in the Middle Atlas cedars cover 741,000 ac., and oaks and Aleppo pines about 620,000 acres. The revenue derived by the state from the exploitation of forest amounted to 1,500,000 francs in 1921.

Phosphate exists in great quantities—estimated at 100 million tons with a yield of 65%—and a decree of 1920 reserves to the sultan's Government the right of prospecting and exploiting the deposits. A start was made in 1917–8 in extracting manganese in eastern Morocco and some thousands of tons have been produced. An oil-field extends from Fez to Laraish.

*Trade.*—The total foreign trade of Morocco increased from 375,000 tons, valued at 178 million francs, in 1912 to 553,000 tons and 1,056 million francs in 1920. The total foreign trade of the French zone (in 1,000 francs) rose from 319,580 in 1917 to 573,160 in 1919, excluding the commerce *via* Algeria, which amounted to 66,660 in 1917 and over 134,000 in 1919. English trade increased from 63,000 in 1916 to 134,500 in 1919. Spain tripled and America quadrupled her trade with Morocco during those years. Of the exports, 98% went to, and 63% of the imports were derived from, France and Algeria.

The following table gives the sea-borne trade of the various zones in 1913 and 1918:—

| | Imports (in 1,000 francs) | | Exports (in 1,000 francs) | |
|---|---|---|---|---|
| | 1913 | 1918 | 1913 | 1918 |
| French zone | 181,427 | 257,580 | 40,182 | 97,042 |
| Tangier | 24,455 | 31,600 | 3,408 | 5,820 |
| Spanish zone | 25,335 | 35,402 | 2,876 | 6,960 |

The animal products exported from Morocco in 1919 were as follows:—

| | Weight (1,000 kgm.) | Value (1,000 francs) |
|---|---|---|
| Eggs | 8,626 | 44,949 |
| Goatskins | 1,828 | 13,590 |
| Wool-grease | 1,480 | 5,243 |
| Sheepskins | 1,387 | — |
| Cowhides | 439 | 2,269 |
| Wool | 104 | 922 |
| Wax | 112 | — |

The trade of Casablanca had increased from 185,000 tons in 1912 to 425,000 tons in 1920.

*Communications.*—There are regular services from Europe to the Moroccan ports of the Cie. Gén. Transatlantique, Cie. de Navigation Paquet, Royal Mail Steam Packet, Bland (Gibraltar), Correos de Africa, and other lines, including Dutch and Italian.

A system of roads has been planned for the French zone; on Jan. 1 1920 2,600 km. were completed, 364 in progress and 247 surveyed. Motors are largely used for mails and passengers, *e.g.* between the ports and Marrakesh. The only road, as contrasted with tracks, in the Spanish zone was (1920) from Ceuta to Tetuan, though another was being constructed between Laraish and El Qasr. In that year the Tangier–Fez road was completed in the Tangier zone, and nearly so in the French, but was practically untouched in the Spanish zone.

The railways in the French zone, military lines (2-ft. gauge) open to civilian use, were being gradually changed to standard gauge (4 ft. 8½ in.). In 1920 there were 610 m. of railway. The line linking Ujda *via* Taza with Fez (198 m.) was completed to Tuahar (168 m.); this will later be joined by the Casablanca–Fez line, *via* Rabat and Meknes, which in 1920 ended 10 m. beyond Fez (221 m.). Of the Casablanca–Marrakesh line (324 m.) *via* Ber Reshid, which in 1920 stopped at Kaid Tuasi (96 m.), 40 m. had still to be laid. A branch line runs from Ber Reshid to Wad Zem (83 m.), to be continued to Khenifra. In eastern Morocco a line under construction from Seflet to Utat el Hajj (19 m.) was open as far as Mahirija. In the Spanish zone a narrow-gauge railway runs from Ceuta to Tetuan, and another from Tetuan to Rio Martin. There are two light railways from Melilla to Nador, Selwan, Tiztutin and the mines. In 1920 a line was projected from Melilla to Taza *via* Tafersit, and a coast line to Tangier. Work on the standard-gauge Tangier–Fez line had not actually begun in 1920, though the survey for the French section had been made. The line from Laraish to El Qasr, which will eventually join it, was half completed in 1913; the French have projected a line from Casablanca *via* Rabat and Kenitra to join it at Petit-Jean (132 miles).

Aeroplanes were much used in Morocco by the French during the war and will be increasingly employed for commerce. There were in 1920 a number of aerodromes, including one 6½ m. from Tangier, and a mail-passenger service, calling at several towns in Spain, plied between Rabat and Toulouse eight times a month each way.

Efficient postal services exist in the French zone; Spain has post-offices at her ports; in 1920 the only foreign post-offices were those of Great Britain, at the chief ports, and at Fez, Meknes, El Qasr, and Marrakesh. There are wireless installations at Fez, Marrakesh, Tangier, Mogador and elsewhere. A telegraph line runs across the Spanish zone from Tangier to Arbawa (French zone). Telephones are installed in Tangier and in all the towns of the French zone; Casablanca, Rabat and Kenitra are connected by telephone, and so are Tangier, Arzila and Laraish. There are submarine cables between Casablanca and Brest; Casablanca and Dakar; Tangier and Gibraltar; Ceuta and Tangier; Estopona and Peñon de Velez; Tangier and Oran and Cadiz.

AUTHORITIES.—The output of books and periodicals on Morocco during recent years has been enormous; only a selection can be mentioned here. A. Bernard, *Les Confins algéro-marocains* (1911), *Le Maroc* (4th ed. 1917), *La France au Maroc* (1917); E. Doutté, *Merrakech* (1905), *En Tribu* (1914); L. (E. G. S.)

**MORRIS, EDWARD PATRICK MORRIS,** 1ST BARON (1859–), Newfoundland statesman, was born at St. John's, Newfoundland, May 8 1859, and was educated at St. Bonaventure's College and the university of Ottawa. In 1884 he was admitted a solicitor and in 1885 was called to the bar (Q.C.1896). The same year he was elected Liberal member for St. John's. In 1889 he entered the Cabinet, and from 1890 to 1895 was Acting Attorney-General for Newfoundland. From 1893 to 1906 he was director of the Newfoundland Savings Bank. In 1897 he went to England as a delegate to the Colonial Office on the question of the French fishing rights. In 1898 he left the Liberal party and became leader first of the Independent Liberals and later (1908) of the People's party. In 1901 he again visited England as a delegate, and in 1902 he entered the Cabinet as Attorney-General, afterwards becoming Minister of Justice. In 1904 he was knighted. In 1909 he became Prime Minister, retaining this office until 1918. In 1909 he represented New-

foundland at the Imperial Defence Conference, and filled the same position at the Coronation and Imperial Conference in 1911. In 1913 he was made K.C.M.G., and in 1917 was a member of the Imperial War Conference. The same year he received the freedom of the City of London. In 1918 he retired from the premiership and was raised to the peerage. Lord Morris produced an important legal work known as *Morris's Reports*, an edition of the Newfoundland law reports from 1800 to 1904.

**MORRISON, GEORGE ERNEST** (1862–1920), British traveller and journalist, Peking correspondent of *The Times* from 1897 until 1912, when he resigned to become political adviser to Yuan Shih-k'ai, president of the newly proclaimed Chinese republic, was born at Geelong, Victoria, Australia. He displayed early in life a love of adventurous wandering and an insatiable curiosity concerning every phase and aspect of human affairs. Until his service with *The Times* obliged him to establish his headquarters at Peking, which he came in time to regard as his home, his career was an unbroken series of journeys, in which his love of adventure on unbeaten tracks was usually combined with some practical purpose of exploration. Thus, in 1882, he studied the Kanaka labour question in the South Sea Islands as a sailor before the mast. Later in the same year he crossed Australia on foot, from the Gulf of Carpentaria to Melbourne, covering 2,043 m. in 123 days. His next journey, to New Guinea, nearly cost him his life; he returned from it with two spear-heads in his body, which were eventually removed by Professor Cheyne at Edinburgh, under whom Morrison concluded his medical studies. In 1887 he took his M.D. and C.M. degrees, but the life of a medical practitioner had no attractions for him. After journeys to the United States and the West Indies he worked for a time in his medical capacity, first at the Rio Tinto mines in Spain and then as court physician to the shereef of Wazan in Morocco. From 1890–2 he was in charge of the hospital at Ballarat. In 1893, wearying of routine work, he set out to travel in the Far East; in the following year he made a journey overland from Shanghai to Rangoon, and described it in a work entitled *An Australian in China* (1895). This journey laid the foundation of his reputation and led to the engagement of his services by *The Times*. In Nov. 1895 he went as special *Times* correspondent to Siam, where the French Government's claims in the region of the Mekong valley had necessitated negotiations for an agreement with Great Britain. Here he did excellent work; in Feb. 1897 he accepted the appointment offered him by *The Times* as resident correspondent at Peking, and for the rest of his life all his work and interests became centred in China. He never attained to any degree of proficiency in the Chinese language, but in the course of numerous journeys during the ensuing 20 years he visited every province and dependency of the Empire, with the exception of Tibet, and acquired an intimate knowledge of men and affairs in every part of the country. In 1907 he travelled from Peking to the borders of Tonquin, and three years later from Central China to Russian Turkestan. During the siege of Peking legations by the Boxers in 1900 he displayed conspicuous gallantry and initiative, and was specially mentioned in despatches by Sir Claude Macdonald. In Jan. 1905 he was present at the triumphal entry of the Japanese army into Port Arthur, and subsequently represented *The Times* at the Peace Conference which resulted in the Treaty of Portsmouth.

At the outset of the revolutionary movement in China (Oct. 1911) Dr. Morrison frankly proclaimed his sympathy with the Republican programme of Sun Yat-sen and the Cantonese Radicals, and advocated the abdication of the Manchu dynasty. In Aug. 1912, six months after the abdication, he became one of several foreign advisers engaged by the Chinese Government, with special duties as political adviser to President Yuan. When, during the stormy period between 1913 and 1916, it became evident that Yuan Shih-k'ai intended to restore the monarchy in his own person, there were occasions when Dr. Morrison's position was somewhat delicate, because of the prominent part which he had played as an advocate of Republicanism, but his unfailing tact and good humour, combined with his unquestionable devotion to the best interests of China, enabled him to fill this difficult position and to retain the goodwill and respect even of those who differed from his political opinions. For nearly 20 years his modernized Chinese house, with its famous library of works on China, was a place of pilgrimage for travellers in the Far East, and "Morrison of Peking" was a name familiar in all parts of the world. He died at Sidmouth May 30 1920.

**MORTON, LEVI PARSONS** (1824–1920), American banker and politician (*see* 18.882), died at Rhinebeck, N.Y., May 16 1920, his 96th birthday.

**MOSBY, JOHN SINGLETON** (1833–1916), American soldier (*see* 18.890), died in Washington, D.C., May 30 1916.

**MOSELEY, HENRY GWYN JEFFREYS** (1887–1915), British physicist, was born Nov. 23 1887. He was educated at Eton, where he entered as a King's scholar, and at Trinity College, Oxford, from which he graduated in 1910 with honours in natural science. His earliest research work was undertaken in Rutherford's laboratory in Manchester, whither he went as lecturer in physics after leaving Oxford. He at once gave evidence of unusual ability both as an original thinker and skilful experimenter. After two years he resigned his lectureship in order to devote more time to research work, and was elected John Harling fellow. The researches with which his name is specially associated were those made shortly before his death. Rutherford had announced the nuclear theory of atomic structure which required each atom to consist of a minute positively charged nucleus about which negative electrons were distributed. It seems also that the charge would increase with the atomic weight of the element. It had been suggested, and Bohr had adopted this view, that the nuclear charge was equal to the atomic number, *i.e.* to the number of the element in a complete series of the elements arranged in ascending order, but hitherto no atomic property had been discovered which could be definitely represented by this number. Moseley, shortly after the discovery of the diffraction of X-rays by crystals, set to work to examine the X-ray spectrum of a number of elements each of which he made in turn the target of an X-ray tube. He found that his crystal-grating gave a spectrum of two lines for each element and that their frequency increased by definite steps as he passed from one element to the next; indeed, the frequency of vibration associated with each element was a simple function of a number which he found to be identical with the atomic number. It is now generally accepted that this number, experimentally determined by Moseley for a number of elements, defines the physical and chemical properties of the particular element. This number is probably to be identified with the electric charge upon the nucleus of the atom. From the regular progression of the lines in the X-ray spectra of different elements Moseley was able to indicate the number of elements yet to be discovered, and he cleared up certain anomalies in the periodic tables of the elements. He laid the foundation of what will probably prove to be a new and more precise form of chemistry (*see* CHEMISTRY, and MATTER, CONSTITUTION OF). Moseley was in Australia with the British Association in 1914 when the World War broke out; he returned to England, obtained a commission in the Royal Engineers, and was killed by a Turkish bullet on the Gallipoli peninsula on Aug. 10 1915. (W. G. D.)

**MOSS, SIR (HORACE) EDWARD** (1852–1912), British director of variety theatres, was born at Manchester in 1852 and in 1877 opened the Gaiety theatre, Edinburgh, first of the Moss's Empire theatres, which by 1912 numbered twenty houses and represented a capital of over £2,000,000. He was the principal pioneer of the changes which have transformed the old music-hall into the modern variety theatre, and in recognition of this fact, and for his charities, he was knighted in 1905. He died at Middleton, Midlothian, Nov. 25 1912.

**MOTOR TRANSPORT, MILITARY.**—Transport by motor vehicles has very profoundly modified the art of war. Their employment enables a commander—despite the unwieldiness of modern armies—to achieve surprise effects which give him victory. The utilization in modern warfare of the enormous

effectives which constitute national armies was made possible only by the railways, which are alone able to assure the supply of food and munitions needed by such a mass of humanity. But steel tracks are by nature rigid, and the employment of motor transport on a large scale has both expanded their functions and rendered them supple. It is by the organized combination of these two means of transport that it is possible to rain on the enemy such rapid and effective blows that he must succumb. Strictly, the railways in times of peace function under conditions quite comparable to those of war. For the economic requirements of peace no less than of war demand incessant and strict attention to ensure railway efficiency. On the other hand, there is only a distant comparison between the use of motor vehicles one by one in times of peace and their employment in compact groups during war operations. There is, therefore, a special interest in trying to trace, after the experience of the World War, the technical facts which would serve as a basis for the employment of motor transport on a large scale in future operations. In the following account, illustrated by practical examples, taken from the use of motor vehicles during the operations of the Allied armies on the French front, there will be discussed the general principles underlying (I.) transport of troops, (II.) transport of *matériel* and (III.) intensive traffic on roads.

## I. Transport of Troops

*The Vehicle.*—Troops have sometimes been carried in ordinary touring-cars. During the battle of the Marne (Sept. 9 1914), at the moment when the French army of General Maunoury was massing outside Paris, there were grouped together all available taxicabs to take direct to the front the infantry of a division which, arriving by rail from the Vosges, was detraining in the stations of the northern suburbs of Paris. This method can only be employed in exceptional cases, because the car or taxicab has so small a carrying power, requiring one driver for every three or four combatants carried, while such vehicles for the most part differ in speed. On the other hand, such motor-vehicles as are designed to convey a larger number of passengers in peace-time, *e.g.* motor omnibuses or *chars-à-bancs*, are eminently serviceable. Thus it was in motor omnibuses, which were employed in the first transport groups of the French army, that there were carried to Belgium, at the beginning of Aug. 1914, the detachments of infantry which operated in support of the cavalry. In the same way the British army employed at the outset the London motor omnibuses; and the "Bus Park," which was placed behind the centre of the English armies, was always able to supply rapid transport for reserves behind the front. Motor omnibuses, sight-seeing vehicles, private motor cars, and all other vehicles of a similar character utilized in towns in peace-time, have the advantage of being always prepared to carry passengers. They have often, however, the disadvantage of having been built for street use and not for any and every kind of route; moreover, they are useless for any other form of transport except for carrying men, so that they will often remain useless when the army has no need to move troops and yet the need for the transport of *matériel* is pressing. A park of motor omnibuses represents therefore a collection of drivers and machines that is frequently immobile; one must be very rich in means of transport to enjoy this luxury, and one can never be so rich when operations are active.

The ideal vehicle is the common motor lorry (or truck, as Americans call it). It is necessary to adapt it, *i.e.* to place in it movable benches, which can be very rapidly installed when it is necessary to carry men, and can be removed without difficulty when it is necessary to carry *matériel*. In accordance with the capacity of the body, which itself partly depends on its load capacity, the lorry can carry from 16 to 25 men with their arms and equipment. The lorry is designed for travelling long distances over indifferent roads; having solid rubber tires, it does not suffer from breakdowns through punctures.

The method of loading men into lorries also requires consideration, since the efficiency of transport depends considerably on it. One good rule is for the driver or his assistant to supervise the loading, and to get the men on board first, their arms and baggage following them. It is necessary to appoint a "chief of the lorry" who takes charge of the interior and keeps good order. Again, it is advisable to be very careful lest men lie on the floor boards and breathe the exhaust gases: this is a very serious cause of asphyxiation. It is, therefore, necessary to see to the ventilation of the lorry and to ensure that the exhaust pipes are in good condition.

During the World War not only were units of infantry transported but also artillery formations; likewise, in some exceptional cases, cavalry with their horses. How can horses most easily be carried? The body of the lorry must be as large and the bottom as low as possible, to make the loading more easy, and the ceiling must be high enough to prevent the horses from being injured by striking their heads. In accordance with these arrangements, the horses may be placed either lengthwise or crosswise. But they should be close to one another, to save them from bumping; and there should be no difficulty of access to where their heads are, in order that they may eat and drink on the road. These precautions taken, it has been found that horses travel as well by motor lorry as in a railway wagon.

Is it better, generally, to have for transport of troops heavy lorries (of 5 tons or greater freightage) or lighter lorries (of 2–3 tons)? This question has often been the subject of controversy. Experience shows that, with a proper arrangement of movable benches, it is possible to put in a heavy lorry, which has a very large body, many more men in proportion than in a light lorry; and it must not be forgotten that, for the greatest efficiency, one driver and one machine must carry the maximum number of men. On the other hand, if heavy and light lorries are both available, and troops as well as *matériel* have to be transported, it is better to use the light lorries for the transport of troops.

*Organization of Lorries.*—Lorries move grouped in formations of varying importance, but two essential conditions must be observed: efficient control and effective maintenance. In proportion as there are built up and put into motion larger and larger masses of lorries, it is necessary to organize a succession of commands in such a way that each will be provided with proper supervision and direction. A type of organization modelled directly on that of infantry or artillery is here unsuitable. The basic unit, the smallest formation to be placed under the orders of an officer, should be formed of 15 to 30 vehicles. The officer who commands this unit is the veritable sheep-dog of his troop of lorries; he must himself have a touring-car (which should be open and not too fast), so as to allow him to follow his lorries when they are on the move, and above all when they are formed into a large column. The officer ought not to lead himself, but be able to keep his attention free, and to jump quickly from his car and speak to his drivers. In a large column the lorries ought to follow one another as closely as possible, because the efficiency of the route is dependent on the continuous progress of the lorries; a certain distance must be kept so as to allow the driver of a lorry to take note of what the lorry ahead is doing, and thus avoid collisions. This distance, which tends to increase uphill and decrease downhill, should average 10 metres at night, when marching with lights extinguished. The drivers ought to be trained to keep their exact distance. For this purpose it is useful to paint, at the back of the lorry, marks on a white ground, perceptible to the eye even in complete darkness. The use of luminous paint has been found practicable. Next above the basic unit (which takes various names according to the armies, *e.g.* "section" or "platoon") is placed the "company" or the "group," normally comprising three or four sections. The commander of the group or company is no longer the sheep-dog of his lorries; he is the shepherd. It is he who guides them in their itineraries, places them in billets and allots them to their work. He must, therefore, have a much more powerful touring-car, so as to be able rapidly to reconnoitre ahead. He should have a liaison officer, with a motor bicycle or cycle-car, to transmit his orders rapidly, and also a second in command, to maintain continuity. There should be as many lorries in a group or company as are needed to transport a battalion of infantry. If the battalion has 1,000 men and the lorry holds 20, there must be 50 lorries always

available. But, as some will always require repair or overhauling, while others must be used as service lorries for replenishing food supply and petrol (and also as workshops), the theoretical number is 65 lorries.

The second point in an organization is to ensure effective maintenance. Automobiles require constant care on a long journey, *e.g.* 200 km. At least a dozen out of 100 lorries will have breakdowns or need repair. Some will even fall out, too seriously damaged to go on, and will have to go to the "automobile park." Minor casualties must be attended to, however, as soon as possible. That is the rôle of the workshops. If the workshop is to move with the group, it must be on lorries, and have a stock of tools and various spare parts. To form a workshop for 20 lorries, *i.e.* for a section, means a large drain on workers and *matériel*, and is only advisable when the section has to remain isolated. If the section remains with the group, it is better to form a stronger workshop for the group, reserving two or three vehicles which can have a real arsenal of spare parts, each having two or three picked mechanics attached, with several skilled assistants to attend them. The commanding officer of the group can delegate to one of his subordinate officers (the most capable from the technical point of view) the direction of the workshop.

As soon as large transport movements have to be carried out, higher control above the group must be organized. The transport of the infantry of a division requires 12 groups. Placed in a column on the road, this would make a file 36 km. in length, a reasonable distance for each group being 3 kilometres. This mass would be formless and incapable of manœuvring unless vivified by organization.

It is a common saying that the action of a commander ought to be limited to directing four immediate subordinates and no more. Experience of large demands on transport during the war shows, however, that six groups could be united under one control, if the commander in charge was supported by a fully qualified staff. Such was the composition of the grouping in the French army: such or something very near it was the composition of the "Bus Park" of the British army. The grouping of six groups had a capacity for 6,000 infantry. When transport by automobile has reached a further extension, the group becomes in its turn a basic unit; and it is in studying the rôle of the commander of the grouping and his staff that the working realities of troop transportation can be grasped. It will suffice to note that the groupings ought also, when they are called on to function together, to be united under a superior control. The automobile service of the French army, which comprised 25 groupings in 1918, had a dozen "commanders of transport reserves" to direct them—each reserve comprising two or three groupings.

*Organization of Troop Transports.*—Let it be supposed that a grouping is ordered to execute the transport of 6,000 infantry, to take them up in their billeting area, and to bring them to the field of battle some 100 km. from billets. What problems must be solved in order to accomplish this mission to the greatest advantage? In the first place, the commander must fix the embarkation-points, *i.e.* the points at which the infantry will be loaded into lorries. In order that this operation may be quickly carried out there must be many loading-points functioning at the same time; to embark one battalion (1,000 men) into a group (80 lorries) requires from 20 minutes to half an hour. The usual procedure of the French automobile service is to place the infantry in column, two deep, and to make them move in this formation. The automobile officer in charge of the embarking-point marshals the drivers of the lorries, at the rate of one per lorry, near to a point where the column of infantry in twos moves out. He divides the column, as it passes him, into small parties, according to the number for each lorry, and assigns each to a lorry driver, who leads his men at the double to the rear of his lorry.

When all the parties are grouped behind the lorries, they embark. At the embarking-office, while the backs of the lorries are closed, the crank-handles are turned and the engines are started up. But even so, with a single embarking-point practically three hours are required for embarking 6,000 men; and in another half-hour the lorries will have covered 8 kilometres. The six groups will therefore find themselves, on the march, separated by a considerable interval, and the total column will be 48 km. in length—altogether too long. Further, there may be great gaps in the billeting area in which the embarking infantry are stationed; and it would be a mistake to make them cover great distances on foot in order to reach a common embarking-point when the lorries can just as well come and pick them up near to their own billets. Consequently it is much preferable, if possible, to have six points of embarkation, each corresponding to a battalion, the hours of embarkation being fixed in such a way that each group of lorries, leaving as soon as the embarkation is completed, will take up its normal position, one behind the other, at the "starting-point" for the common itinerary.

When the commander of an automobile grouping has then prepared the organization of his embarkation-points, he must come to an agreement with the infantry headquarters concerned as to the time and place of embarkation of each battalion; such an agreement is much simplified if the orders of the higher authority responsible for the movement have specified a precise time for the start. The work which devolves upon the command of the lorry grouping in the disembarkation of the troops is generally similar to the above; but there is an additional difficulty, caused by uncertainty as to the exact points of disembarkation, which often depend at the last moment on the military situation. Nevertheless, the procedure must be arranged as early as possible, in close touch with the higher staff which has to fix the disembarkation zone; and an understanding must be arrived at with headquarters as to the probable alternatives, between which a decision will be made later, when the lorries are quite near to the arrival zone. It is not possible for the commander of the grouping to do this work of preparation for arrival and for departure by himself alone; he must have another officer in his confidence to help him. While he is making arrangements and reconnaissance in the zones of departure and arrival, he must also choose (or at least reconnoitre) the itinerary between the two zones. And when the itinerary is reconnoitred, it must be marked out. This is the duty of the officer assisting the commander of the grouping. The "route officer," with his own staff, marks the itinerary by posting up placards (and, for night work, hanging lanterns) bearing the distinguishing mark of the grouping and an arrow indicating the direction of the march and the route to take. The distinguishing mark of the grouping is necessary because, in a period of movement, many other groupings will often wish to use some portion of a route in common. Moreover, any lorry which has become isolated or left behind must be enabled to rejoin by following the arrows.

Further, the commander of a grouping is responsible for the care of the well-being of his personnel and *matériel*. He has to supply his lorries with petrol and his men with food, and must organize the movement of his service lorries, supply lorries, work lorries, lorries for towing, lorries for cooking. Here again the commander's control of details depends first on his supply officer, and next on his technical officer, the latter being especially concerned with the workshop of the grouping, the repairing organ. It is the technical officer's endeavour to interrupt the grouping as little as possible, and to follow it up, if it is not returning to its previous zone of billets, with any laggard lorries that have needed repair. He must, therefore, organize repairing squads who will follow different columns and leave nothing behind.

*Transport of Complete Divisions.*—When a larger unit, like a division of infantry, has to be transported, two or three lorry-groupings are required. The same general principles, however, apply. An interesting example occurs when, together with the infantry of a division, it is necessary to transport all or part of their artillery with its horses. This will happen less and less frequently as the artillery itself tends to become an entire automobile arm, since it will then move simultaneously on its own account; but with horse-drawn artillery it may be a very serious matter for a general of a division not to be able to bring up to the battlefield, in support of his infantry, the artillery who are accustomed to manœuvre with him. It is thus very desirable to be able to transport artillery with horses.

The loading of guns and limbers on lorries does not present any special difficulty; it is sufficient to have fixed rules for putting the *matériel* in place, and these are the same as the loading-rules for the same *matériel* on railway wagons. This is true both for heavy artillery and for artillery of small calibre. As for the horses, they accommodate themselves perfectly to this manner of transport. At the time of the different German attacks in 1918, especially in May and July, there were on the French front enormous transportations of complete divisions which attacked as soon as they were unloaded from the lorries. The automobile almost completely takes the place of the railway, securing much quicker travelling and better surprise effect. There is always one condition, that the troops thus transported can live and fight with a limited quantity of baggage, all their supplies being assured by lorries to the complete exclusion of horse transport. An example may be given from experience in 1918, when the Higher Command had under consideration the possibility of obtaining a great success in Italy. A study of this move, developed in every detail, shows that, with the resources in automobiles which were then available for release from the French front, it was possible, after twelve hours' warning, to move three divisions—complete with divisional artillery, machine-guns, cookers and a number of horses equivalent to three pairs per wagon and two per gun—and to transport them in seven days from the region of Châlons in France to the region of Mantua in Italy. Stages of 15 hours (including one hour for a general halt) would have had nine hours of complete rest between. Three distinct routes were prepared, with provision for petrol depots and workshops, guides, police, and so forth. Undoubtedly this unexpected movement of three divisions, so rapidly as to ensure secrecy, would have had a decisive influence. And it is just such possibilities that are bound to enter into the strategic conceptions of the future.

## II. Transport of Matériel

Lorries are not specialized for the transport of *matériel*. The same type is employed as for troops, and therefore the organization is similar. A lorry-group capable of moving a battalion of infantry can alternatively move 100 tons of *matériel*. Experience in the World War has shown that, during the periods of active operations, a division requires an average of 200 tons per day in foodstuffs and ammunition. This is equally true in the case of defensive areas, as at Verdun; in offensive actions of the type of the Somme battles in 1916; or those of July, Aug. and Sept. 1918, on the Marne. Two groups are therefore required for the supply of a division, subject to the distance from the railway being at furthest within a radius of 40 kilometres. Four groups are necessary if the division is 70 km. from a railway. An average of 3 hours must be reckoned for loading at the stations; with allowance for difficulties arising amid intensive operations, 7 or 8 hours are taken up on the journey and 2 hours in unloading. This gives about 13 hours for work, and leaves 11 hours per day for the maintenance of *matériel*, feeding and rest. If the traffic operations are to be continued for a number of days, any more than this cannot be demanded of the personnel or of the *matériel* without risking excessive wastage. On the day after a journey with loads the vehicles return empty, and on the day after that they recommence the journey loaded. As 200 tons a day are required for a division there must be a double set of two groups, with a total capacity of 400 tons.

There has been much argument as to which is the more efficient type of lorry for the transport of *matériel*, the light lorry of 2 or 3 tons' capacity, or the heavy lorry of 5 tons. Before the war, military experts in all countries had a marked objection to the heavy lorry, which was gratuitously supposed to be difficult to handle on bad roads and unsuited for average military requirements. This opinion is now out of date. The first objection does not hold good in countries with a network of well-maintained roads, such as is found in western Europe. The second objection has equally fallen to the ground, since the greater part of transport work is concerned with munitions, which represent weight rather than bulk. The full load is never used in a lorry, however light, if it only carries bread; and only the employment of a trailer allows of the maximum efficiency. Unfortunately, the employment of trailers has great inconveniences, notably in the manœuvring required for loading at stations. Systematic attempts have been made to find a regulation method of yoking a trailer to every 5-ton lorry when it is necessary to transport personnel, or *matériel* of light weight (forage or bread). These trailers have not been very satisfactory: the motor consumes more, and tires wear more; the rate of movement is slower, and any economy in drivers is an illusion.

To sum up it may be said that, for war service, lorries from 2 to 5 tons of average load are equally useful, but that it is useless, as was done before the war, to give prizes to induce constructors of lorries to design vehicles on the light side. In the organization of transport one obtains the greatest efficiency by giving a preference to the light lorry for the transport of personnel and of light *matériel*.

*Non-Specialization of Matériel.*—At a general mobilization, like that at the opening of the World War, the resources available for transport are necessarily limited not only by financial conditions, but by the number of vehicles in existence in the country capable of being requisitioned, and by the maximum production of the manufacturing firms. On the other hand, there is no limit to the requirements in lorries, because no general worthy of the name thinks he has a large-enough stock of transport at those critical times when every addition means an increase in his power of manœuvre. During the 20 days which intervened between May 27 and June 15 1918, the lorries of the French army had to transport about 800,000 tons of foodstuffs and munitions, in order to ensure the supplies of those armies which were making headway against the German attack. And yet during this same period the French Headquarters Staff had transported by automobile the infantry of 63 divisions. It was necessary also to make numerous evacuations of public records, civil populations, hospitals and engineer parks. This wonderful effort was only possible because in the French army the principle of non-specialization was adopted. Every lorry was controlled by the motor transport service of the armies, and was utilized by it for any form of transport needed. No vehicle was specially or permanently attached to this or that higher or lower formation. When a higher formation, such as a division, had need of transport, the automobile service arranged the transport, but as soon as it was finished the lorries employed on this service returned and were available for other transport services. In short, the lorry capital never remained unproductive.

Unfortunately, the tendency of every service, and of all units subordinate to it, is always to oppose this idea of non-specialization, which ought to be the aim of the Higher Command, whose interest is always to obtain the maximum return on lorry capital. In effect, each service desires to have a special allotment which becomes its own property, and calculates always the value of this "indispensable" allotment by the eventual requirements—the day when the work will be heaviest. But if such demands for special attachments are not very energetically resisted, capital fritters away without any profit.

Supposing that ten lorries are united to one definite formation under the pretext that it may have to make rapid moves at a considerable distance, in practice this rapid move will occur perhaps not once in a month, and in the interval the ten lorries will remain in park. During this same month those lorries in normal use would have been able, if they have a capacity of 2–5 tons and travel 100 km. per day, to do more than 60,000 km.-tons of work, with allowance for overhaul. They could have moved a depot of munitions of 1,000 tons for 60 km. or have maintained the supply of bread every day for a division. It might be supposed that a wide-awake staff, having made this allotment of 10 lorries, would not let them remain idle, but would order the formation conceived to undertake such and such transport of a general kind. But such a practice is only possible in calm periods. As soon as troublesome times arise everybody is fully occupied; the formation does not wish to lose the ten lorries which it will need—and for the very purpose for which it was given them—at a moment when it will not be able rapidly to replace them; and it is pre-

cisely at the moment of crisis that the Higher Command will have the greatest need of regaining control of all those resources which it has imprudently dispersed, and it will be entirely unable to do so. On the other hand, if the commander has not made any special allotments, but has kept all his lorries under his immediate care, he will be able to organize the moves which he wishes to effect in accordance with the degree of urgency imposed by the operations he desires to carry out. If he thinks it well to move the formation which was taken as an example, he will allot immediately ten lorries for this move, and they will return as soon as the move is completed. If the formation is not to be moved, there will not be ten lorries lying idle.

*The Use and Duties of Depots.*—The reasons for avoiding the wastage of lorries apply likewise to avoid wastage of movements. The carrying-out of "detail" transports is the principal cause of low efficiency. In the battle of Verdun, March 1916, the supply of munitions was taken by rail to Bar-le-Duc and to Baudonvilliers. Trains of munitions arrived daily at these two stations to supply the artillery of the ten divisions deployed around Verdun, some 60 km. from the stations. If, to supply each of these divisions, there had been allotted a motor formation, which could come to load up at the stations and go as far as the batteries, bringing munitions, the efficiency would have been mediocre and uncertain. In effect each of these motor formations would have been under the constant repercussion of the events at the front and the difficulties of moving about in the front areas. An accident at a depot, an interrupted road, an advance or a check at the front, would set back the whole time-table of the formation, and one would have seen them arriving in the station for loading their lorries in twos and threes in disorder, and at different hours. The whole organization and supervision of traffic would have been impossible.

There can never be efficiency unless there is regularity of movements. It is never possible to have regularity unless the traffic of the back areas, which can be regular, is definitely separated from the traffic of the front areas, which is always uncertain. How can this separation be effected? By the creation of depots depending on the lines-of-communication authorities, and supplied by them where the formations from the front areas come to refill exactly as they would refill from the railway if there were stations at these fronts. On this principle was organized the transport of munitions for the army at Verdun, as well as the very considerable movements of troops which took place in these operations. The troops were disembarked at stations between Revigny and Ligny-en-Barrois, and their transport to Verdun, as well as that of the supplies, was carried out by the single artery formed by the road Bar-le-Duc–Verdun, which came to be known as the "Sacred Way" and formed the *route gardée* reserved for motors. Through a complete understanding between the motor control at Bar-le-Duc and the railway control at St. Dizier, it was possible to regulate the workings of formations in such a way that the lorries were brought to the stations for loading at the same moment that the troop trains or munition trains arrived there. In continuous movement all formations, when loaded, went via Bar-le-Duc and followed the Sacred Way as far as the unloading point. They at once returned by the same Sacred Way to Bar-le-Duc, and took up their places at their own camp; and after a minimum of time for rest they left for a new town at the order of the regulating staff ("Commission regulatrice automobile," hereafter called the "C.R.A.") of Bar-le-Duc. Movement was continuous. The question of unloading or disembarking was dominated by the necessity of keeping free the *route gardée*. It was therefore necessary at the outset completely to alter the location of the munition depots which had been placed along this route—at Neippes, Lemmes and Verdun itself—so as to permit of "sidings" where lorries could be placed for the duration of the unloading process, which consisted in piling up the munitions along the siding. It was necessary to open fresh munition depots more suited to these working methods, and in this way came into existence the circuits of Regret and of Nixeville, about which were organized a series of lorry stations with stores of *matériel* and supplies of every kind. On the same principle, although at the beginning troops were disembarked in any and every piece of road that led to the Sacred Way, either beyond Verdun or N. of Moulin-Brûlé, it became the rule later to build veritable "stations" for the personnel.

It was to these stations that the C.R.A. directed its movements of personnel and at these same stations troops due for relief came to embark. There also were collected casuals, leave-men and, in particular, the slightly wounded, who at fixed hours took their places in empty lorries on their return journey to Bar-le-Duc.

This situation may be summed up by saying that the employment of the route Bar-le-Duc–Verdun was as strictly conducted as if it were a railway. One looks in vain for any other parallel. The intensity of movements required it, for in addition to the movements mentioned above one must add that of numbers of isolated cars and lorries, of every kind, which entered and circulated on the *route gardée* from the moment that it was given over to the motor vehicles.

### III. Intensive Traffic on Roads

*The Route Gardée.*—The command can only depend on movements by motor transport when they are executed with absolute punctuality and in accordance with programme: they must resemble movements by rail and be based on time-tables, just as in railway work. It is essential that breakdowns, and the resultant lagging behind scheduled times, be notified at once. For the organized employment of automobiles on the roads, like that of railway trains, the essential condition is to be master of the road. If, on a road, this or that mishap can take place without it being in someone's power to neutralize its effects, or if all and sundry are permitted to put columns of troops or vehicles on it, it is useless to attempt to carry out important movements. Congestions multiply, and their effect is reflected farther and farther back, leading to accidents, and increasing delay to the degree of stoppage; so that, whatever may be the efforts of those in charge of the movement, their transport fails. It is an absolute rule, based on numerous experiences, that it is not possible to launch a big transport movement involving several hundreds of lorries without being absolutely certain of the complete freedom of the road. Nor does it suffice to be certain at any one particular moment; it must be certain during the whole time that the movement will last. Hence the organization of the *routes gardées*, with their personnel of guards and their traffic orders.

A *route gardée* is not necessarily reserved exclusively for automobiles, though this may be so, as with the *route gardée* from Bar-le-Duc to Verdun. But there are other cases where one has to admit, under certain conditions, the movement of horse-transport. Such was the route Amiens–Bray. But in every case there must be a responsible authority, having power to give orders and have them carried out. In the French army, during the war, this authority was a motor regulating staff (C.R.A.). In the British army, the control of traffic in France was part of the duties of the Provost Marshal (A.P.M.). The organization of the route, on a railway model, is based on the "block-system." The route is divided into a series of districts, each of which is under the direction of a district chief, having assistants for supervision. The district chief is in constant touch by telephone with the neighbouring districts, and with the office of the C.R.A.; he knows all the movements which affect his district, and also keeps a record of all movements which occur there and all the incidents of the traffic. Thus at the office of the C.R.A. it is always known what the state of the traffic may be on every *route gardée*, and the necessary arrangements for launching an important movement can be made in given time.

The route orders for the *routes gardées* are more or less drastic according to the breadth of the road, and whether or not there are relief routes. On the Verdun route, where the traffic was most intense at certain hours (one vehicle every five seconds), the narrowness of the road—seven metres—necessitated very strict rules: every broken-down lorry was thrown off the road; no lorry could range up alongside the preceding lorry, and so on.

The length and the importance of the districts on a *route gardée* depend, obviously, on special difficulties which they have to

overcome, *e.g.* the number of adjacent routes, the localities traversed, narrow passages, etc. Between Bar-le-Duc and Verdun there were six " districts " varying in length from 5 to 10 km.

It is quite unnecessary to guard in this permanent fashion a route over which there is not continuous traffic. Whenever such a road is needed, for the time being, for an intensive transport, it is sufficient to occupy it immediately and transform it into a *route gardée*. This requirement leads to the C.R.A. (or any corresponding organization) being given a territorial zone of operation. In each zone it is the immediate business of the C.R.A. concerned to guard any portion of the road over which the transport will be moving. For this purpose the C.R.A. had at its disposal specially organized personnel which may be fairly accurately designated " mobile districts," and which, being in the habit of operating in this way and supplied with the means of rapid installation, can in two or three hours make themselves masters of the traffic on whatever part of the road is entrusted to them. It is well understood that a C.R.A., to whom a zone of operations has been entrusted, prepares as minutely as possible this bringing into action of the mobile districts on a plan of some kind over its route-system. For instance, it installs in advance a network of telephone stations; above all, it establishes and puts into place enormous placard indicators showing the direction of localities, designations of the routes, local traffic, war maps, etc.

A C.R.A. that has organized its zone of operations properly is really master of it; it installs a few permanent districts on the main roads, and has several mobile districts, always at disposal, which are thrown out each day wherever traffic makes it necessary. In the French automobile service system during the war, this rôle of the C.R.A. was facilitated by the fact that the commissions were at the same time executive transport authorities. The head of the C.R.A. was also commander of several " groupings " of transport, and he was responsible for carrying out all military motor transport work required by the army within the territorial limits of his zone. He was thus the first to be informed of any large movement of automobiles in his zone.

*Maximum Efficiency over a Road System.*—When one is master of circulation throughout a given region, one is free to aim at maximum efficiency. How is this obtained? Formerly, when the staff proposed to carry masses of troops to a theatre of operations it traced the greatest number of parallel and serviceable roads which led to the zone of action decided on, and there was thrown on each of these roads a column of all arms scientifically echeloned in depth. Thus it was that Napoleon moved from the Rhine to the Main in 1805; thus, also, Moltke moved from the Sarre to the Moselle in 1870.

When this system is applied to present-day conditions the efficiency of the road system is low, because the increase of speed due to the automobile is not turned to account. All modern armies have tractor-drawn heavy and automobile light artillery, and possess the means of transporting the bulk of their infantry by motor lorry. There remain the horse columns, on which it is no longer necessary to impose the speed limitations of marching infantry. In consequence, in coördination with the movements made by railway, the movements by road ought to be organized in the form of special itineraries, on each of which move columns of elements that are homogeneous from the point of view of speed. Thus combination of movements can be worked out in which much time is saved, as compared with the old methods.

We will examine further the conditions of carrying out strategical movements on the road. From the point of view of traffic organization, these considerations lead to the principle of allocating the available *routes gardées* according to type of traffic. Thus, such a route is reserved for heavy artillery on tractors having a speed of 8–10 km. an hour: another route is allotted to motor field artillery; others for motor lorries, and yet others for horsed columns—a distinction being made between the requirements of light columns (field artillery and trains) and heavy columns (heavy artillery and bridging equipment). One must also remember, in the distribution of these itineraries, the quality of the roads, their breadth and the strength of the road bridges. Thus one is led to a completely new technique in the utilization of the roads, for which one must know the output of each itinerary for the given density of traffic which it is proposed to put on it. One must work out the crossings and the doublings of the columns, and, above all, the way to place all these elements of different speed so as to make as many different " moving stairways " as there are rates of movement.

The existence of regulating commissions in charge of zones of movement, and masters of the traffic, considerably eased the French problem. But the regulating commissions must have control not only of automobile traffic, but of all traffic: in their zones no movements must occur without their having received notice and taken the necessary measures to facilitate the execution of the movements in question. They must be able to arrest all false movements in good time. And they must be in close touch, so as to form a complete network, covering the whole area over which it may be necessary to move any column.

It was by the functioning of an organization of this nature that the French army was able to make its concentrations of considerable numbers of troops at very short notice in March, May and July 1918.

*Strategic Transport by Road.*—What is a strategic transport, or, in a wider sense, a strategic move? It is a movement capable, by its results, of affecting the present or future situation of a battle. In war, when the forces are equal on both sides, the only way to act effectively on the opponent is by means of surprise—a word that must be interpreted in the widest sense. The problem is not only to dazzle the enemy by unexpected blows, but also to secure that the blows get home. It is necessary to be stronger than the enemy where he believes he can cope with you, and as strong as he is where he believes he can overcome you.

The battlefield of Rocroy was no more than 2 km., that of Austerlitz no more than 10 kilometres. The French front of 1914–8 was 500 km. long. In modern warfare, up to 1914, one counted only on railways for strategic transport for the large higher formations: the plan of concentration was exclusively a plan of transport by rail, and the movements by road leading to the battle were only the immediate consequence of the deployment of these higher formations on their railheads.

As the automobile has brought on the road again the tourist who had deserted it since the middle of the 19th century, so transport by motor lorry has brought into use again strategic movements by road. And, for the production of surprise effect, by adding the roads to the railways, it has been possible to put to full use all available means of communication.

The air alone has not been utilized; but it may be foreseen in the future that it must be utilized for quick transport of combatants. In order that movements by roads should be serviceable, it is necessary for them to be rapid and powerful; this is attained by applying the same principles as in rail movements—that is to say, the temporary break-up of large units for transport.

To understand these principles better, an example may be taken from the situation of Sept. 16 1918 on the Allied front in the region Toul-Verdun. The American army had at this time, to the E. of St. Mihiel, 8 divisions, which, with corps and army troops, were quite equivalent to 8 French army corps. The orders of Marshal Foch prescribed that this American army should be placed to the N. and N.E. of Verdun, in positions precisely laid down and sharply echeloned in depth, ready to move on the enemy on Sept. 26. Six divisions were coming from different sides, and principally from the region of Chaumont-Neufchâteau; eight would be those already mentioned, which, after carrying the salient of St. Mihiel by a brilliant assault, found themselves in very considerable disorder, as large forces rapidly successful in a convergent offensive must. It was calculated that time admitted of seven nights being devoted—for it was desired to conceal the strategic move entirely—to moving these eight army corps 60 km. from their present position and depositing them in order opposite the new objectives. What was the solution? For movement in suitable stages (three in number) there were available two itineraries, constituted by two roads which in part were very narrow and bad. It would be necessary to put four army corps in succession on each road. Such a movement by road in earlier days,

even if perfectly regulated, would have represented ten days' marching with its accompanying difficulties and fatigues for the troops. How could the food supplies have been assured for the infantry, as it marched by night and halted by day along the route, so as to hide all movement of troops? There would be serious risks of congestion, and even complete paralysis, at those points where there must be crossings with the columns of the divisions coming up from Revigny and Bar-le-Duc. The most experienced staffs would not have been able to solve such a problem. By rail 800 trains would have to be operated over lines of which one part only was capable of much traffic. At 40 trains a day the move would need 20 days: and what sort of platform would be available for embarkation? What, moreover, would become of the surprise? Besides, there was at such a moment plenty of other work for the railways. The new system now, however, consists in the movement by road with broken-up formations, their elements being apportioned in accordance with their capacity for movement; and the different scattered members are brought together at a concentration point. Let us look at all the conditions which such solution requires. There is, first, the presence of a solid advance guard, which at all costs prevents the enemy breaking into a system which is incapable of defence. This advanced guard, in the present case, is the "front." Secondly, there is absolute control of the traffic on the route, and a certain professional ease in the art of handling all the various elements,—putting them on the road, directing them, regrouping them. In this case the necessary skill had been acquired in the development of the regulating organizations at Verdun and on the Somme, during the movements of 1917 (Italy, Péronne) and in 1918 (March, May, July). Lastly, there must be the complete confidence of those who are being carried, who hand themselves over bound hand and foot to their transporters. These conditions being fulfilled, the problem set out above was simplified, thanks to the existence of the two C.R.A.'s of Toul and Souilly, the former having as its sphere of action the zone of departure of the American formations, the latter the zone of arrival. The director of automobile services of the French army placed a delegation at Ligny, which took under its direct orders the two regulating commissions and coördinated their action. This delegation at Ligny dealt with eight groupings of automobiles, with which they carried out the transport of the infantry by lorries.

Let us enter into details, and see what are the different operations with which the delegation at Ligny would have to deal, to organize these movements at the outset.

(1) After a rapid evaluation of the kind and quantity of the effectives to be moved—motor transports of infantry, the American divisional motor convoys, teams of the horse-drawn divisional or corps artillery, motor artillery—this staff sets out on the map the different current-paths in which these elements can be analyzed. In the first place, the great road Toul–Void–Ligny–Bar-le-Duc–Chaumont-sur-Aire–Souilly–Nixeville (or Chaumont-sur-Aire–Chermont-en-Argonne) is reserved for transports of infantry by the French motor reserves. A current of motor artillery traffic is deflected to the S. by Gondrecourt. Lastly, two routes N. of the line Toul–Ligny-en-Barrois are reserved for horse-drawn vehicles and horse artillery. These four streams distribute simultaneously all the units of the four types, arrangements being made for the American divisional motor convoys to follow the French motor convoys of infantry transport.

(2) This being done, arrangements are made for the orders of march of each of the elements following the four itineraries. This work involves specifying the character of the elements, their places of departure (date and hour), their points of transfer from the authority of the C.R.A. of Toul to the charge of the C.R.A. of Souilly, and their points of final destination; and all these arrangements when worked out are submitted for the approval of the operations branch of the American general staff, which draws up all executive orders to be sent for despatch to each unit affected. These orders are sent in duplicate by the delegation at Ligny.

(3) The picking up of each division by its lorries necessitates the working-out and despatch, by the delegation at Ligny, of orders to the two C.R.A.'s of Toul and Souilly, also to the commanders of the various automobile formations concerned. The order prescribes the day and hour of the picking up; the address of the divisional headquarters staff; the billeting distribution of the division; the routes of empty movement to bring their lorries to the embarkation stations, and the routes loaded which are to bring them to their destination; the place of assembling the empty automobile units after they had unloaded; the limit of a zone within which empty movements must not take place after 8 A.M.; points of liaison either by telephone or motor orderly between the delegation at Ligny and the commander of the automobile formation. In conformity with the standing orders of the directorate of motor services, this order would instruct the commander of the automobile formation to make his plan of transport in conjunction with the C.R.A. of embarkation and C.R.A. of disembarkation.

This manner of operating has the advantage that an officer of the C.R.A., perfectly familiar with his region and its road system, takes part in working out his embarkation plan; it enables the loops to be determined by which the different automobile units arriving at the different places of embarkation will assemble. It was the same for the disembarkation.

(4) The D.S.A. of Ligny, using the preliminary table of the *ensemble* of the movements, draws up detailed tables of the movements on which figure the place, the date and the hour of departure of each element, whether horse-drawn or motor; the itinerary in the American zone; the point of handing over from one to the other; the itinerary in the French zone; and the final destination. To establish these detailed tables consultation is necessary with the American staff, and also with the staff of the 2nd French Army at Laheycourt which looks after rationing and billeting areas.

(5) In the course of the movements the American operations section made certain modifications in the list of formation units which it had communicated to the delegation at Ligny. These modifications consisted either of omissions or substitutions, as in the case where one division took the place of another in the new order of battle. The desire to deal suitably with the special qualities of each American division necessitated modifications of this nature. In order to maintain the most exact order in the prescriptions concerning the movements, the delegation at Ligny tabulated a general summary for each day, to which was added in the course of the day a numbered series of "additions" or "alterations." The chief table and the supplementary tables were notified immediately to the two C.R.A.'s affected, who in their turn gave orders to their district chief commanders. The principle which served as an absolute guide was at all costs to make good the movements as they were ordered, in establishing as rapidly as possible the liaisons necessary, in particular with the unit in motion, to be certain of the time-table.

The difficulty of these transports and movements had been considerably increased by the need of secrecy to cover the operations of concentration. General Pershing, who commanded the American I. Army, had definitely ordered that no movement should be visible to the enemy observers able to fly over the American zone. In consequence all movements, without exception, had to be carried out at night, and it was absolutely forbidden to use any light whatsoever, be it touring-car lamp or lorry back-lights. This applied equally to movements on foot. Thus it was in complete darkness that the elements had to be put on the road, march discipline assured, circulation controlled and liaisons established. On Sept. 25 the concentration was achieved as the C.-in-C. had ordered.

*Combined Use of Railway and Motors.*—The foregoing was an example of a strategic movement carried out solely on the roads. In the majority of cases, however, use is made of railways and roads in combination. The end to be attained is always a rapid move of powerful forces; the staff should therefore make use simultaneously, and as efficiently as possible, of every means of transport which it possesses. Under what conditions will this simultaneous employment give the best results? Is it better to carry out end-to-end movements, parallel and simultaneously by railway and by roads, or, on the other hand, to make movements by railway for one part of the journey, and to prolong these movements by automobile? The question and the answer apply both to transport of troops and to the transport of *matériel*.

The weak point in transport by railways is not in their capacity, for this is very considerable if there are available both a double railway track and a quantity of locomotives and wagons sufficient for the full exploitation of the system. One must never lose sight of the fact that the efficiency of the railway is much superior to that of the road; a train of 50 wagons is equivalent to 150 lorries. At a speed of 30 km. an hour, and with 4 departures an hour, one has four trains in a length of 30 km., or the equivalent of 600 lorries. We have seen that 600 lorries form on the road a length of 20 to 25 kilometres. Railway and road have therefore very nearly the same output. But the lorries, going 25 km. an hour, are only half as quick. Further, at the end of 100 km. it is necessary for the lorries to stop in order to rest the drivers, for, save in exceptional cases, relief crews are out of the question, while trains travel indefinitely without changing locomotives. The weak point in transport by rail really lies in the necessity of having stations for embarking and for disembarking. Save in quite exceptional cases it is an absolute technical neces-

sity to load and unload in stations, and even so only in those where there are sidings sufficient to take the military trains so as to leave free the main line during the times of embarking and disembarking. Without this precaution all the traffic will be blocked. Further, when it is a question of loading *matériel* it is necessary to place it on the platforms. While special platforms or docks are indispensable on the railway, it is always easy, on the road, to find and organize quickly loading-places for lorries; on the railways to install even simple sidings is a serious matter.

Big movements by railway can be made only from a zone A to a zone B, if the two zones A and B are equally rich in loading-places. But—apart from those points which come into the initial concentration scheme, and on which therefore work can be done in peace—it is impossible to ensure, in the large movements which military operations may necessitate at any given moment, that the beginning and the end of rail transports shall take place in zones that are rich in loading-places.

On the other hand, it is generally possible to find, within a radius of 50 to 100 km. in the zones A and B under consideration, one or more regions rich in loading-places. The normal combination consists therefore in utilizing motor transport to prolong railway transport, and to carry the troops or *matériel* (1) from their stationary zone to the places of embarkation, and (2) from their places of disembarkation to the zone of operations. The relatively short movements (50 to 100 km.) it requires are those in which the efficiency of the lorry is at its greatest. And between the two zones of loading thus actually used, the efficiency of the railway will equally be a maximum.

Examples of combined use of rail and road systems were very frequent in the course of the war. In Oct. 1914 all French troops despatched for the Ypres region were carried by rail to the region N.E. of Arras (Doullens, St. Pol, Béthune, Bailleul) and pushed forward from there by automobile to Ypres. Similar arrangements were made on every occasion in the course of the war on which the French army was called upon to put considerable forces into this region. For example, in April 1918, in the movement of reinforcements to Flanders, the French employed three *routes gardées*, by which, though they cut through the lines of communication of the British armies, formations picked up at the railway stations of disembarkation around Amiens and Arras were despatched to the Ypres region.

Naturally, other combinations are also practicable: for example, that by which, on Nov. 20–21 1917, 3 French divisions were to be carried from Meaux and Château-Thierry to Péronne; the infantry, with their machine-guns and cooking-carts, being conveyed in motor lorries, and the artillery by train. The object of these movements, very quickly ordered on Nov. 19, was to reinforce the successful British attack in front of Cambrai with the first use of tanks in mass, and had overwhelming results. While the embarkation of the artillery was proceeding at railway stations in proximity to the divisional billets on the Marne, the C.R.A. of Meaux and Château-Thierry loaded up on 3,000 lorries the infantry, etc., of the 3 divisions. The movements of the lorries, made by 3 separate itineraries, came to an end in the neighbourhood of Péronne, where a C.R.A. of disembarkation put the various elements in their places in the zone where the 3 divisions were re-forming. At the same time the British motor service was working with full efficiency on all the routes converging from the N. and W. on this same region of Péronne. In every case there must be the closest liaison between the authorities who regulate the movements of the trains on the railways and those who regulate the movements of motors on the roads. In the case where troops are loaded into lorries on leaving a train, it is necessary that the motor transport should be constantly informed by the rail-transport authorities of the hours of arrival arranged for the trains, in order to have the lorries at the disembarkation platforms in good time for immediate loading-up of the troops. Finally, as in the case of the move to Péronne, where there were parallel moves by rail and roads, there must be a complete understanding between all concerned, so that, both in the zone of departure and in the zone of arrival, the hours of embarking and disembarking should be so arranged as to avoid crossings of columns and overcrowding; and the working-up and reconstitution of higher formations, whose elements are conveyed partly by rail, partly by lorry, partly again by marching, must be minutely worked out and definitely fixed. A final example may be given of the combined use of the automobile and railway. In this instance it is required to make a rapid movement of certain troops to a zone where, for some reason, it is not possible to use the railway system. Here, combination is needed in the disembarkation and reëmbarkation arrangements at the beginning and the end of the zone; such operations are easy where the two organizing departments of the railways and automobiles are directed by the same superior authority and kept in strict and constant touch. If, after Oct. 1918, the pursuit of the German armies had not been arrested by the Armistice, this problem would have had a thoroughly practical demonstration, for it is probable that the Allies would have been able to take into use the railways existing beyond the devastated zone. In Nov. 1917, at the time of the crossing of the Alps by a portion of the French troops, the C.R.A. of Besançon and of Nice had to deal with an analogous case; viz. to set in motion and to transport over the passes of the Alps those troops which, having been disembarked from the French railways at the foot of the mountains, were to be reloaded on the Italian railways on the other side.

It must be observed that there are many details which complicate considerably the task of the transport officials: such as the question of food supply for the troops during their transportation and at their disembarkation, and the question of moving troops simultaneously with the building-up of the munition dumps which they will require. One last remark should be made: transportation by automobile and by railway, which, we have seen, supplement one another happily in regard to distance, is equally satisfactory in regard to time. Large movements by railway require a concentration of *matériel*, often difficult to achieve; and, in the case of moves decided on in a hurry, the possibility of motor transports on a large scale assumes very great importance, since it takes 4 or 5 days for the railway to show its full powers.

*Conclusion.*—The experience of the war shows the rôle which transport by motors is called upon to sustain becoming more and more important. The Allied armies, together, placed on the French front about 20,000 vehicles of motor propulsion in Oct. 1914; four years later the number exceeded 200,000.

As regards troop transport alone, the power conferred on the command by the employment of lorries had grown enormously during this period of four years. At the time of the Armistice, the inter-Allied transports reserve, the creation of which had just been decided on, was of a size to transport simultaneously 10 divisions of infantry complete, with all their means of fighting, machine-guns and artillery included. This was a fighting mass of more than 100,000 men, which the Higher Command was able to pick up at short notice and carry at the speed of 100 km. a day to any point where it was required.

As regards the transport of *matériel* at the end of the war, it had become possible—independently of the resources just mentioned—to keep supplied with food and munitions 40 divisions at a distance of 100 km. from the railways.

To show what was actually achieved in those directions, it will be enough to say that, in the French army alone, there were carried by motor transport during July 1918 1,040,000 tons of *matériel* and 950,000 combatants.

In the future it is to be foreseen that mechanical motive power will replace entirely the animal motive power in the armies. Since the use of special tractors enables the artillery to take up positions in any kind of terrain, there will be no reason for not giving it, on the road, the speed of moving which the automobile allows. And as the support of infantry on the battlefield, *i.e.* accompanying guns and also tanks, will in the future be capable of rapid movement on the roads, it will be natural to organize more and more systematically the rapid conveyance by automobile of considerable masses of infantry. The evolution of strategy must always be in the direction of using all available means to surprise and break the enemy by concentrating unexpected strength with unexpected rapidity.

**MOTOR VEHICLES** (*see* 18.914).—Improvements in design between 1910 and 1920 made the passenger motor-car a more reliable, more comfortable and, allowing for changed conditions, more economical vehicle; they also rendered it more attractive to the eye. During the same period the use of cars greatly increased, particularly in the United States, where registration figures showed that in the state of Iowa there was on July 1 1920 one car to every 5·49 of the population, while for the whole country the proportion was one to every 13·52 people. To a certain extent the World War was responsible for the fact that in the use of motor-cars Europe did not keep pace with the United States. In France, Belgium, Germany and Austria the manufacture of cars for sale to the public ceased absolutely upon the opening of hostilities, and was not resumed until after the Armistice; in Great Britain and Italy, too, motor-car factories were restricted to work for the armies, practically throughout the war. In the United States, on the other hand, not only was there no interruption in production for private account, but the war-born wave of prosperity of 1915–6 increased sales over what they would have been under normal conditions. After the United States entered the war many motor-car plants were turned over to the production of aero-engines and munitions, and had the war continued after Jan. 1 1919 the manufacture of passenger cars for other than military purposes would have ceased in America as completely as in Europe.

The chief reasons, however, for the preëminence of the United States in the use of motor-cars had nothing to do with the World War. In the first place America is a land of magnificent distances; in many sections towns and cities are far apart, and long trips must often be made over the public roads, for which purpose horse vehicles are quite unsatisfactory. Secondly, petrol (in the United States called gasoline), the fuel commonly used for motor vehicles, is a native product, comparatively cheap and plentiful. Thirdly, *per capita* wealth is greater than in most countries and well distributed. Not all conditions were favourable to the introduction of motor-cars however. Whereas the industrial countries of Europe had magnificent systems of hard-surfaced roads, such roads were practically non-existent in the United States at the beginning of the motor era; but while a handicap, this did not prove a serious obstacle. In the early years of motor-car development the private passenger car was generally regarded as a means of pleasure, and in Europe this remained its chief function. But in the United States and Canada (which comes next after the United States in respect to number of cars owned, notwithstanding its comparatively small population) it became a great factor in business life. In New York City, for instance, a very large proportion of the street traffic in 1920 was by motor, and in the main thoroughfares horse vehicles were almost a rarity. On the other hand, such agricultural states as Iowa and Nebraska had relatively more cars than the industrial states, and the farmers, too, used their cars chiefly for business purposes. As the substitution of the motor-car for the horse came about gradually, it did not greatly impress the general public; nevertheless it profoundly influenced modern life.

Conditions in Nyack, N.Y., a town of 5,000 inhabitants, 25 m. from New York City, may be cited for illustration. In 1905 Nyack had only one motor-car, owned by a physician; in 1920 deliveries of all articles of commerce, from the morning newspaper to coal and building material, were made by motor vehicles, with the one exception of goods delivered by the railway express, which still adhered to horse service. The junkman made his rounds in a motor-car. All moving of household goods was effected by motor-van. Motor-buses were the only means of public transit, and in addition to making their regular trips they carried children in the outlying districts to and from school. The fire department had been "motorized." A large proportion of the residents owned private cars, which they used for driving to church or to the theatre, for shopping and visiting, as well as for pleasure-driving. On Saturday afternoons the main business street was so crowded with cars that it was often difficult to draw up to the curb.

In the cities of the United States the once familiar horse-cabs and hansoms had practically disappeared before the motor-propelled taxicab by 1920. There were bus services competing with the tram services, though these had not been developed to the same extent as in the leading European cities. Numerous bus lines had been established in country districts beyond tram services. About 1915 many owners of private cars began carrying passengers in competition with tram lines, their vehicles being known as jitney buses (jitney, a Russian coin about equal in value to five cents, then the common tram fare). These jitneys did much business, especially during the "rush" hours when people go to work and return home, as their passengers avoided the crowding of the street-cars and the annoyance of frequent stops. But after a short time the greatly increased cost of petrol and war conditions rendered the business unprofitable, and little more was heard of jitneys. Many cars of the private type were still offered for hire, but five cents was no longer a sufficient fare, and the drivers usually called their vehicles taxis, though in the smaller towns as a rule they carried no taximeter.

Motor-trucking and the haulage of freight by motor vehicle began to assume importance in the United States only about 1910. This branch of the industry up to then had been more successful in Great Britain and Germany. Beginning with that year, however, it consistently increased in the United States, where under the stress of war conditions the motor-lorry even entered into competition with the railways. An enormous amount of motor freight traffic grew up over certain routes between important industrial cities, as between Detroit, Mich., and Toledo, O., and between Akron and Cleveland, O. One large tire manufacturing company in Akron, O., with cotton mills in Boston, Mass., over 600 m. away, established a fast freight service between these two distant cities by means of motor-trucks on pneumatic tires. Some of this development was evidently due to the abnormal conditions which made railway freight service inadequate during and immediately after the World War. Military operations gave a great impetus to motor-truck development (*see* MOTOR TRANSPORT, MILITARY). Thousands of motor-trucks were employed by the armies on both sides. The Central Powers were greatly handicapped in this respect, as, owing to the blockade, they could get no rubber for tires, and during the latter part of the war their army trucks ran on wood and steel tires. All of the material for the American army in France was transported by motor-trucks from the landing points to the battle-line. In addition to the urgent demand for trucks for military purposes there was also a strong demand for business purposes, owing to the intense industrial activity and to the breakdown of the railways under the war strain.

The substitution of the motor-car for the horse was beneficial in various ways. In the first place the car is much more speedy and more comfortable for transport. With a motor-car a physician, for instance, can extend his practice over a much wider territory; contractors can oversee more thoroughly a number of projects under way at the same time; stores and factories can deliver goods in the country, at distances of 30 m. or more, in their own vehicles, whereas with horses their delivery territory was limited to the city. Stables, always a nuisance and a breeding place of disease, have been practically eliminated from cities, and street-cleaning has been rendered much easier. Real estate remote from railways has in many instances considerably appreciated in value as a result of the advent of the motor-car, which rendered it accessible to the city man.

In the foregoing the utilitarian aspect of the motor-car has been specially emphasized. While cars are still being built that can properly be classed as vehicles of sport and luxury, they form a small proportion of the whole production. In New York City an annual show was established for this class of car; it started as the Importers' Salon, but during the World War, when the importation of European cars was hedged about with many difficulties, it gradually changed its character and became a show of high-grade domestic as well as imported cars. At the salon in Nov. 1920 there were exhibited cars selling at upward of $20,000, whereas a serviceable five-passenger car could be bought for as low a price as $550. The luxury cars exhibited at these shows were characterized by high power and high speed, elegant body finish, fine upholstery and superior equipment.

In tracing motor-car development in Europe between 1920 and 1921 it is necessary to distinguish two periods,—before

and after the outbreak of the World War. During the former period development proceeded normally, from both a technical and a commercial standpoint. Great Britain had the greatest number of cars in use, but France was the greatest producer, about one half of the French production being exported. In continental Europe the introduction of motor-cars was hampered by heavy taxation on the cars themselves and on the fuel. The use of motor-trucks, on the other hand, was encouraged by the so-called subsidy system, by which purchasers of trucks suitable for military purposes were offered by their Governments a bonus on the purchase price and also on the upkeep cost, in consideration of their keeping the trucks always in fit condition and agreeing to turn them over to the Government in case of war. Great Britain, France and Germany had such subsidy systems before the war; Japan adopted the same policy later. As soon as war was declared the motor-car factories were set to work for the war departments, either making trucks or other vehicles for the transport corps or else manufacturing aero-engines or munitions. Soon all the petrol available was needed in war service and the use of motor vehicles by private parties practically ceased. In England some use was made during the war period of town gas for motor fuel; this was carried in a collapsible bag of rubberized fabric, on the roof of single-deck omnibuses for instance. With this fuel it was possible to obtain about 85% as much power from an engine as with petrol, and a satisfactory mileage on one filling was secured. Under normal conditions the gas would have been carried in steel bottles under high pressure, but owing to military requirements no steel could be spared for this purpose. The Central Powers suffered much more from fuel shortage than did the Allies, and extensive researches on substitute motor fuels were carried out in Germany. After their petrol supply ran low the Germans used benzol, petroleum mixtures, benzol-alcohol mixtures, alcohol, wood alcohol, tar oil, gas oil and shale oil, as well as compounded fuels known under the names of electrol, benedixine and melanol. Shale oil was derived from a raw material said to be intermediate between bituminous clay and lignite. Benzol was recognized as a valuable motor fuel, and its use continued, even after petrol was again available.

*Registration in Great Britain.*—The British Ministry of Transport during the summer of 1921 issued a statement of the number of motor vehicles of different kinds for which licences had been issued under the new motor vehicle tax law during the period Jan. 1–May 31 1921. These included 212,000 private passenger cars, 370,000 motor-cycles, 95,300 public passenger vehicles and 16,000 lorries. According to the same authority there were licensed in Great Britain on March 31 1920, 185,700 private passenger cars, 278,600 motor-cycles and 71,400 public passenger vehicles, there being no record of the number of lorries for that date.

*Registration in the United States.*—The figures given in Table I are based on information furnished to *Automotive Industries* by the registration officials of the different states. Allowances were made for re-registration of cars sold by their owners during the registration year and for registration of cars by non-residents, and the table is believed to give as accurately as possible the number of cars in service in each state during the years mentioned by residents of the respective states.

*Registration in Canada.*—Table II. shows that from 1915 to 1919 the number of cars registered increased over 279%.

*Technical Developments.*—In 1908 the "Silent Knight" engine, invented by Charles Y. Knight of Chicago, was adopted by the Daimler Motor Co. of Coventry, England, and within the next few years licences for its manufacture were taken out also by leading manufacturers of France, Belgium and Germany. This engine was notable for its almost silent operation, due to a form of sleeve valve employed, and its introduction had a strong influence on engine development in general during the next few years. In the Knight engine (fig. 1) the usual poppet valves are dispensed with, and instead there are two concentric sleeves between the piston and the cylinder wall. These sleeves are reciprocated by means of short connecting rods from a short-throw crankshaft which is driven at one-half the speed of the regular crankshaft; when ports in the two sleeves and in the cylinder wall are in register there is communication between the combustion chamber and either the inlet or exhaust manifold. In 1908 noise was one of the most serious objections to the ordinary motor-car, and designers of poppet-valve engines were spurred on by the competition of the Knight engine in their efforts to make their engines silent too. They achieved remarkable success by lightening the valves and parts reciprocating with them, by refining the cam outlines, stiffening the camshafts, adopting silent drives for the camshafts and enclosing the valve mechanism. A most desirable feature in a motor-car is flexibility, that is, the ability to pass from a low to a high speed by merely opening the throttle valve. This is secured by using an engine of great piston displacement (a powerful engine) in proportion to the combined weight of the car and load. The much better performance of modern cars, as compared with earlier ones, from the control or "handling" viewpoint, is largely due to the use of much greater piston displacement relatively. American cars have been specially noted for their flexibility, due to the use of very large engines notwithstanding high fuel consumption per mile travelled. As motor fuel was much more expensive in Europe, European designers could not ignore the factor of fuel economy as American engineers could.

In engine design the constant endeavour was to get greater output from an engine of given piston displacement. Horse-power output

depends upon two factors, the mean effective pressure upon the piston head and the linear speed of the piston. It was not possible to increase greatly the mean effective pressure; in fact, changes in the character of the fuel used for motor-cars, by which some very much less volatile fractions were included than were found in motor fuel of the earlier period, made it necessary to operate with lower compression, which resulted in a lower mean effective pressure. Improvements in combustion chamber design and other changes more than balanced this loss however. A great gain was made by increasing the speed of operation. In 1905 the average engine speed corresponding to maximum engine output was about 1,000 ft. p.m.; in 1920 it was above 2,000 ft. p.m. for passenger-car engines and over 3,000 ft. p.m. for racing engines. The first step in endeavouring to increase engine speed was the enlargement of valve ports and passages, to enable the engine to draw in a normal amount of charge at a higher speed. The valve timing was also changed; the exhaust valve being given a greater lead and the inlet valve a greater lag. Next, the reciprocating parts (piston and connecting-rod) were lightened, so as to reduce the inertia forces on them and the bearing pressures resulting therefrom. This led eventually to the adoption of aluminium alloy pistons. One difficulty with aluminium pistons is that owing to the fact that aluminium has a higher coefficient of heat expansion than cast iron, the aluminium piston must be given a greater clearance in the cylinder, which tends to result in unpleasant piston slap when the engine is cold, and also in "oil pumping," that is, transfer of lubricating oil from the crank-chamber to the combustion chamber, with consequent smokiness of the exhaust. For this reason some makers who had adopted aluminium pistons gave them up. Special means were resorted to in attempts to build ultra high-speed engines, as for racing and similar purposes. These included the use of two inlet and two exhaust valves per cylinder, the use of two simultaneous ignition sparks in each cylinder, and the use of crankshafts in which each individual throw was counterbalanced.

It was recognized early in the history of motor-car development that by increasing the number of cylinders above the one or two employed in the first machines, not only could the engines be reduced in weight, but the objectionable vibration could be minimized. In 1920 the four-cylinder engine was the foremost type for use on vehicles of a strictly utilitarian character. The six-cylinder engine was, however, widely used for the larger and more powerful types of passenger car, particularly in the United States, and the eight- and twelve-cylinder engines also had a run of popularity. In a petrol engine the torque impressed upon the crankshaft is always non-uniform, no matter how many cylinders there are, but the fluctuations decrease with an increase in the number of cylinders. In a four-cylinder engine there is, as with one or two cylinders, a reversal of the torque; that is, just before the end of each stroke the flywheel not only supplies all the power delivered by the engine, but also some of the power necessary for keeping the crankshaft and pistons in motion. Six cylinders are the smallest number delivering continuous torque at the crankshaft; but while continuous the torque is still far from being uniform; with eight cylinders the torque fluctuations are reduced, and with twelve they are still smaller. Four- and six-cylinder engines were always arranged vertically, with all cylinders in a row; eight-cylinder engines were generally of the V type with an angle of 90° between cylinders. The Lincoln eight-cylinder car had a 60° V engine, and several all-in-a-row eights were built; twelve-cylinder motor-car engines were always built in V form, with a 60° angle. In deciding upon the form of the crankshaft of a multi-cylinder engine and the angle between cylinders in a V-engine two objects are aimed at, namely, to ensure uniform spacing of explosions and inherent balance of reciprocating parts. Both objects can be attained in six- and eight-cylinder vertical engines and in twelve-cylinder V engines; in a four-cylinder vertical engine there is an unbalanced reciprocating force in a vertical plane, causing vibration of the engine. In an eight-cylinder 90° V engine there is an unbalanced reciprocating force in a horizontal plane.

When multi-cylinder engines were first used the cylinders were generally either cast separately or in pairs; later it became the practice to cast all cylinders in one row in one block. This greatly simplified the outward form of the engine, as with such a cylinder block only one pipe connexion each need be made for the cooling-water inlet, the cooling-water outlet, the combustible charge from the carburetter and the exhaust. Some manufacturers even cast the top part of the crankcase integral with the cylinder block and made the lower part a steel pressing. This construction lent itself well to quantity production. Most makers of the higher-priced cars, produced in smaller numbers, cast all parts of the crankcase of aluminium. In American practice the cylinder heads were generally cast separate from the cylinder block and fitted to the block with a gasket of sheet copper and asbestos between. This construction facilitated manufacturing operations, and when the engine was in service permitted decarbonizing the combustion chamber by scraping without removing the cylinder. It also made it possible to machine completely the combustion chambers, and thus to get all the chambers in one engine of exactly equal volume. European engineers up to 1920 adhered largely to the integral cylinder head.

One thing that caused both manufacturers and users of motor-cars a great deal of trouble between 1910 and 1920 was the continual change in the volatility of the fuel used. When motor-cars were first used the fuel sold consisted of a comparatively narrow range of highly volatile hydro-carbons. When sprayed into air at atmospheric temperature in the required proportion of about one part by weight of petrol to 15 parts of air it vaporized readily. The fuel supplied in the United States in 1920 had an end point of close to 500° F., that is, the least volatile constituents, when under atmospheric pressure, boiled only at that temperature. Hence, in order to vaporize this fuel completely it was necessary to supply heat to the mixture or to the components before they were mixed. When trouble from incomplete vaporization was first experienced the carburetters were provided with a jacket through which hot water from the engine jacket was circulated. When this no longer sufficed the air for the carburetter was drawn through a muff surrounding a part of the exhaust manifold, and to prevent recondensation after the mixture was formed the inlet manifold was so arranged that it was completely surrounded by hot water. Still later this also proved inadequate, and then what is known as the hot spot or exhaust-heated manifold was introduced. When the fuel is incompletely vaporized the liquid particles tend to separate out of the mixture at the bends in the manifold, and it is very difficult to insure that all cylinders get mixture of the same composition. Those portions of the manifold wall where the liquid particles tend to accumulate are then made to form parts of the exhaust manifold wall also, so that they are constantly kept at a high temperature, and the liquid particles upon striking them flash into vapour. The change in the character of motor fuel between 1916 and 1919 is strikingly illustrated by the diagram (fig. 2) of distillation curves of fuels purchased in Detroit, Mich., at various times during 1916–19.

One difficulty encountered in the use of exhaust heat for vaporizing the fuel is that the heat supplied does not vary in accordance with the needs when the load on the engine is varied. When the engine is heavily throttled and runs under light load at low speed, the suction on the spray nozzle is small, and consequently the fuel is not finely sprayed. Relatively more heat is needed to ensure the vaporization of the larger globules of fuel, but under these conditions of operation the exhaust does not supply a great amount of heat. A device designed to overcome this difficulty was developed by the Packard Motor Car Co., and is known as the Fuelizer. With this (see fig. 3) a variable fraction of the mixture prepared in the carburetter mixing-chamber is shunted around the throttle valve and through a heating jacket of the carburetter, where it is kept burning by a constant stream of sparks delivered by a sparking plug. The products of combustion are combined with the main stream of combustible charge and pass on into the cylinder. When the throttle valve is fully open

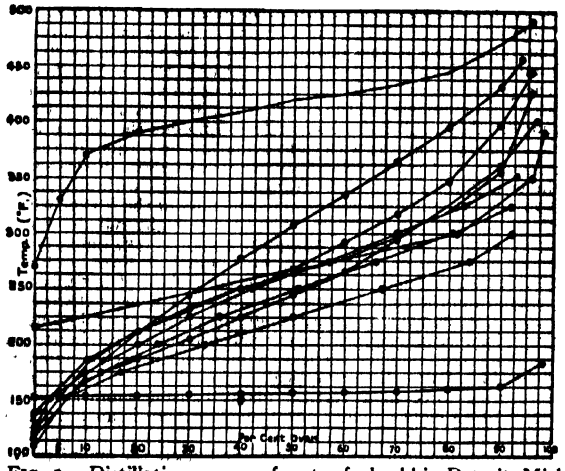

FIG. 2.—Distillation curves of motor fuel sold in Detroit, Mich., from 1916 to 1919. The data for each curve are as follows:—

| Curve No. | Fuel | Date of Purchase | Baumé |
|---|---|---|---|
| 1 | Petrol | 4/5/16 | 60·5 |
| 2 | Petrol | 7/10/16 | 57·5 |
| 3 | Petrol | 9/11/16 | 56·8 |
| 4 | Petrol | 6/9/17 | 56·8 |
| 5 | Petrol | 1/24/19 | 57·3 |
| 6 | Petrol | 4/30/19 | 55·7 |
| 7 | Petrol | 6/18/19 | 55·0 |
| 8 | Alcohol | 10/18 | 42·2 |
| 9 | Cal. Dist. | 18 | 51·4 |
| 10 | Paraffin | 18 | 40·0 |

there is very little resistance to the passage of the combustible mixture past it, and very little then flows through the by-pass or heating jaket; on the other hand when the throttle is nearly closed the passage through it offers much more resistance, and a much greater proportion of the fuel charge passes through the heating jacket, which is in accordance with the requirements.

In early cars the fuel tank was almost invariably located in the front seat, and the fuel was fed by gravity to the carburetter. Later the bodies were constantly lowered, partly to secure greater stability and partly for the sake of appearance, and at the same time the carburetter had to be raised in relation to the engine, owing to the lessened volatility of the fuel. The result was that sometimes when the car had to ascend a steep grade and there was little fuel in the tank there was no head on the fuel, and none would flow to the carburetter. Some of the earlier high-class cars were provided with a pressure fuel feed system, by which gas under pressure, taken through an "adapter" from the engine cylinders, was made use of to force petrol from a tank carried on the frame at the rear to the carburetter. There were two major objections to this system of feed: carbon particles from the engine cylinder often got into the fuel tank (in spite of the gas being passed through a fine-mesh wire-gauze strainer) and thence into the carburetter jet, which sometimes became clogged; besides, every time the fuel tank was filled the compressed gas escaped, and to get an initial flow it was necessary to obtain pressure by a hand air-pump. By placing the fuel tank under the cowl instead of in the front seat sufficient head for gravity feed was generally obtainable, but the cowl tank usually had an awkward shape and was of rather small capacity. The solution was found in the vacuum feed system, which was developed by the Stewart-Warner Speedometer Corp., Chicago. By this system (fig. 4) the suction or vacuum in the inlet pipe of the engine was made use of for transferring the fuel from a rear tank to an auxiliary tank mounted on the forward side of the dashboard, as high as possible. The auxiliary tank had two compartments, an upper and a lower. Into the upper compartment the fuel was drawn by the vacuum, and it was periodically transferred to the lower by a float valve. Thence it flowed to the carburetter by gravity. There was always sufficient fuel in the carburetter float chamber and in the auxiliary tank to start the engine after the main tank had been refilled.

In 1910 ignition on practically all motor-cars was by high-tension magneto. In 1920 nearly all American makes of passenger car had battery and coil ignition. French manufacturers were also adopting battery ignition, while British manufacturers with few exceptions adhered to the magneto. The reason for the change from magneto to battery ignition was that all passenger cars in 1920 were equipped with a generator and storage battery; consequently there was a constant and plentiful supply of current available, and there was no need for an additional current generator in the form of a magneto. As compared with the early coil and battery systems, the only differences consisted in the use of a plain coil instead of a vibrator coil and of a mechanical interrupter instead of a timer. Sometimes safety devices were provided for automatically opening the circuit or reducing the current flow if the operator should forget to open the switch when the motor stalled. No fundamental changes were made in the cooling system with the exception of the introduction of the thermostat for the control of the circulation. This instrument is connected in the cooling circuit in such a manner that it prevents circulation through the cylinder jackets until the latter have attained a certain predetermined temperature, generally about 170° F. The result is that in starting from cold the engine reaches its normal working temperature in much shorter time, and trouble due to incomplete vaporization of fuel is reduced. The thermostat used, known as the Sylphon, consists of a corrugated copper cylinder filled with a liquid which vaporizes at the temperature at which the thermostat is to act (fig. 5). Many passenger-car radiators are fitted with a radiator thermometer in the filler cap, which is a help to the operator in trying to keep his engine running at its best temperature and gives an early indication of incipient overheating.

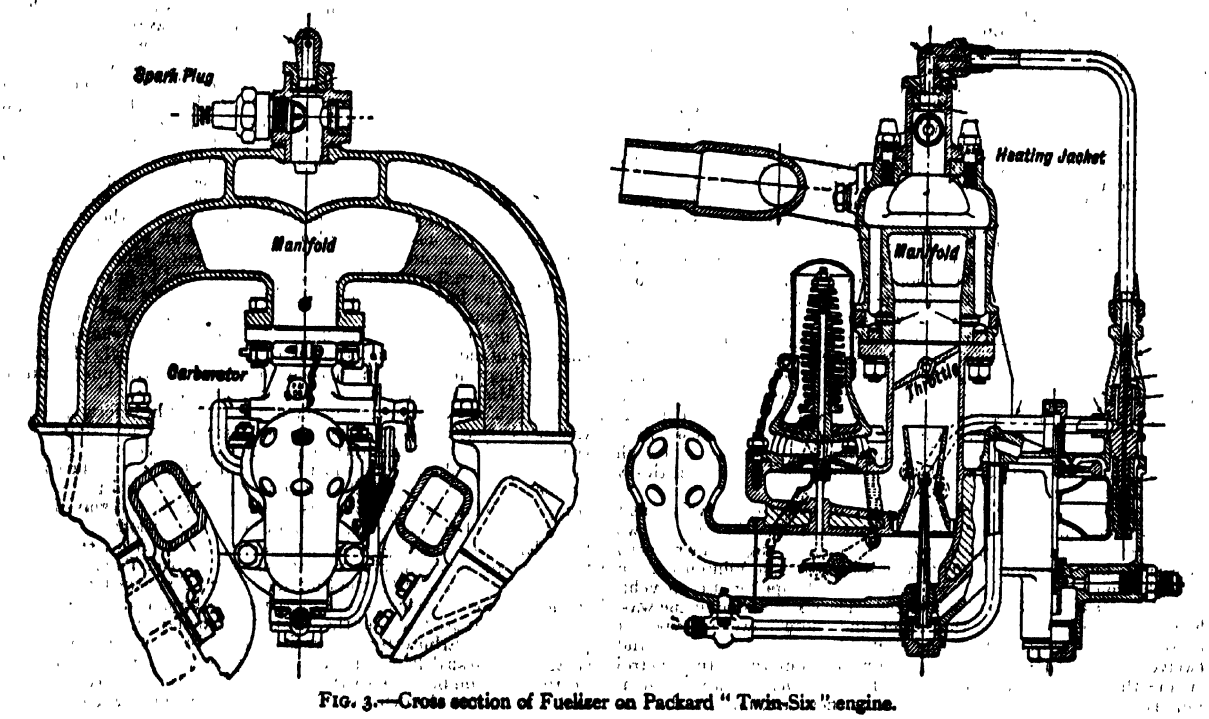

FIG. 3.—Cross section of Fuelizer on Packard "Twin-Six" engine.

As regards engine lubrication two basic methods came into use, the circulating-splash and the force-feed or "drilled-crankshaft" system, as well as combinations of the two. Both systems were employed on early cars, but the force-feed system came into much more extensive use with the development of the high-speed engine.

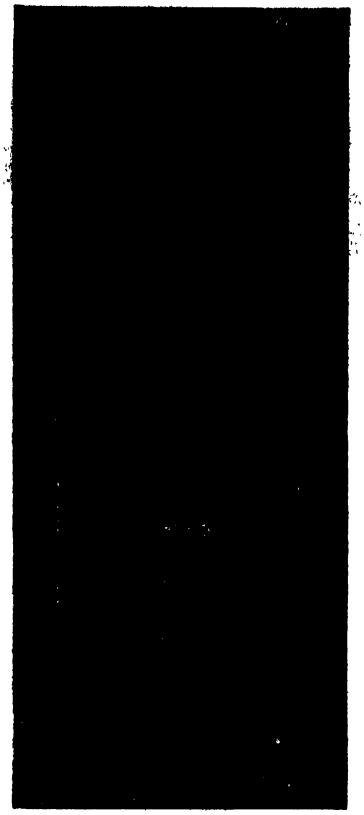

FIG. 4.—Cut-away view of Stewart vacuum tank (fuel feed system).

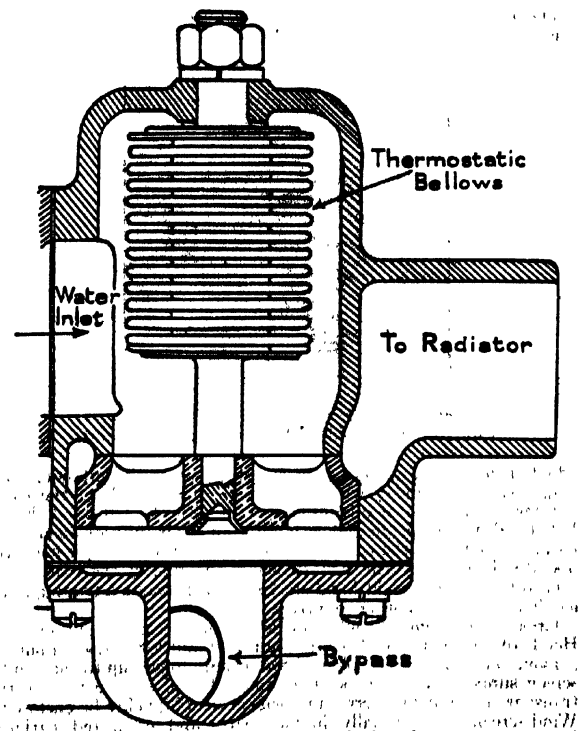

FIG. 5.—Thermostatic valve for control of engine temperature.

The problem of engine lubrication was rendered much more difficult by the change in the character of the fuel used. A good deal of the fuel entered the cylinder in the unvaporized state, and some of it leaked past the pistons into the crankcase, where it diluted the lubricating oil. In 1920 it was a common experience to find a fresh supply of lubricating oil lose much of its viscosity, and hence of its lubricating value, during the first 100 m. of running. Heating of the crankcase oil also reduces its viscosity, and to reduce this heating many British engines were cast with cooling flanges on the bottom of the oil sump.

One of the greatest advances in motor-car practice was the development of electric starting and lighting systems. The first such system on a car in regular production was that of the Cadillac in 1912, and was the design of C. F. Kettering. Electric lighting alone had been used on petrol cars for some years previously, in fact ever since the advent of the tungsten filament bulb. At first the lamps were supplied with current from a storage battery only, which had to be recharged periodically from electric mains; later they were fed with current from a generator and storage-battery combination. The adaptation of an electric generator to storage-battery charging on a motor-car presented considerable difficulties, for the reason that the petrol motor runs at widely varying speeds, and that the voltage of the generator, therefore, tends to vary within wide limits, whereas a substantially constant voltage is needed for charging. Many systems of regulation were used with more or less success, but finally the so-called third brush system was adopted by a majority of the manufacturers of electrical equipment. In this system the generator field was provided with a winding similar to a shunt field winding, but instead of being connected between the positive and negative commutator brushes it was connected between one of these brushes and an auxiliary brush, so that only a fraction of the voltage generated in the armature was applied to the field coils. This system of control did not give a constant generator voltage, but with a storage battery connected to the generator it kept both the voltage and the charging current within permissible limits of variation. In connexion with the electric starter the main problem was that of the drive to the engine crankshaft. After trying various devices nearly all manufacturers in the United States and a good many in Europe settled upon the use

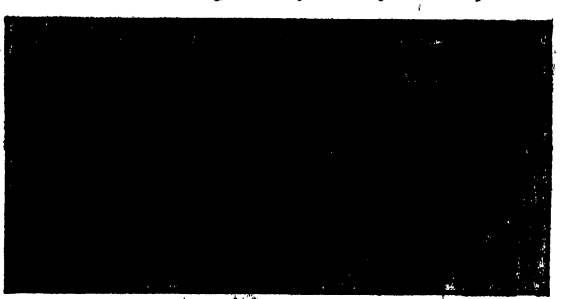

FIG. 6.—Bendix drive for electric starters.

of the Bendix drive (fig. 6), invented by Vincent Bendix of Chicago. On an extension of the starter armature shaft was loosely mounted a sleeve, which was placed in driving connexion with the shaft through a coiled spring. The spring had a coarse, square thread cut on its outside, and on this was mounted the driving pinion, the hub of which was cut with a corresponding female thread. When current was applied to the starting motor, which was always of the series wound type, the armature started to revolve at great speed, carrying along the threaded sleeve on its shaft. Owing to its inertia the pinion lagged behind, and was screwed along the shaft and thus shifted into mesh with a gear-ring on the flywheel rim. Upon abutting against a collar it became fast upon the sleeve, and the starter then cranked the engine, the shock being relieved by the coiled spring. As soon as the engine began to pick up its cycle the flywheel ran ahead of the driving pinion, and the latter was automatically thrown out of mesh by being forced along the screw. Fig. 7, illustrating the Fiat motor-car engine, shows one method of mounting the generator and starter. A necessary part of practically all motor-car electric equipments was a battery cut-out, which automatically disconnected the battery from the generator when the engine speed dropped so low that the generator voltage was less than the battery voltage, and connected it on increasing engine speed when the generator voltage surpassed the battery voltage. Ground return wiring was very much used, all electric appliances having one insulated and one grounded connection. The standard voltage for motor-car electric systems in the United States was six volts, while in Europe a pressure of 12 volts was much used.

Unit-power-plant construction, that is, the combination of the engine, clutch and change-speed gear in a single unit, became very popular, and in the United States was the almost universal practice for passenger cars. A new type of clutch, the dry-disk, largely replaced the multiple-disk-in-oil type and also partly the cone clutch (fig. 8). It was very similar to the lubricated type of disk clutch in construction, but one set of the metal disks was faced with disks of

asbestos fabric on both sides. Its advantage over the lubricated disk clutch was that its operation was not affected by changes in atmospheric temperature, as was that of the latter. There were no important developments in the design of gearsets or transmissions;

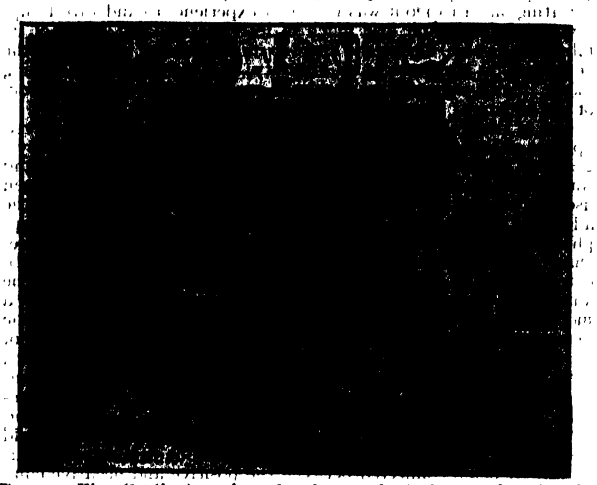

FIG. 7.—Fiat (Italian) engine, showing method of mounting electric generator and starter.

nearly all manufacturers of passenger cars used the selective sliding pinion type, and this type was also on most commercial vehicles.

Chain drive was almost entirely discarded, except on trucks in continental Europe, and shaft and bevel-gear drive became the standard for passenger motor-cars throughout the world. But two important improvements were made in this drive. One was the substitution of spiral bevel for straight bevel gears, to secure quiet operation, and the other the partial substitution of disk universal joints for the metallic type, the former requiring no lubrication. The spiral bevel gear (fig. 9) was made possible by a gear-cutting machine developed by the Gleason Works of Rochester, N.Y., and the fabric disk universal joint (fig. 10) by a fabric structure originated by Ed. J. Hardy & Co. of Coventry, England. Practice in regard to final drives for motor-lorries remained in a chaotic state in 1920. In continental Europe the chain drive was still predominant, while in

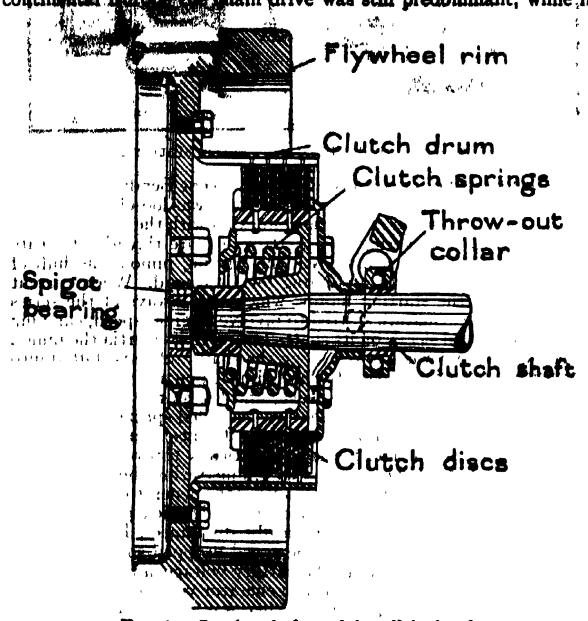

FIG. 8.—Sectional view of dry-disk clutch.

Great Britain and the United States the worm drive was in most extensive use. Of the lorry models manufactured in Great Britain in 1920 roughly 50% had worm drive, 25% chain drive and 25% the double-reduction drive, or drive by one pair of bevel and one pair of spur gears enclosed at the middle of the axle. In the United States the most popular drive next to the worm was the internal gear drive, in which there was a first reduction by bevel gears at the middle of the axle and a second by internal gears at the driving wheels.

In connexion with lorry axles mention should be made of the development, and use, mainly in the United States, of so-called non-stalling differential gears. A vehicle fitted with this type of differential would not lose all traction when one driving wheel gets on slippery ground; on the other hand, in turning corners the drive was

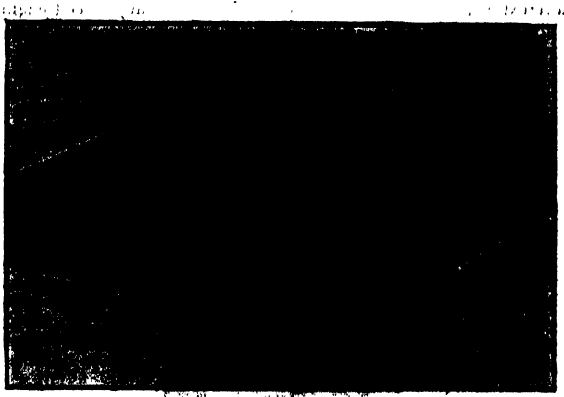

FIG. 9.—Central part of a rear axle with inspection cover removed, showing spiral bevel gear.

entirely through the inner wheel. A type of body suspension spring that gained much in popularity between 1910 and 1920 was the cantilever type first used by F. W. Lanchester in England. The most extensively used type in 1920 was the half-elliptic. Many attempts were made to solve the problem of furnishing the springs with effective means of lubrication, to make them as supple as possible and to prevent squeaking, and in England the practice of enclosing the springs in leather gaiters gained some ground. In the connexion between the rear axle and the frame provision must be made for taking up the driving thrust necessary to overcome the air resistance and the resistance encountered by the front wheels, as well as the reaction to the rear-wheel driving torque, which tends to turn the axle housing in the direction opposite to that in which the wheels are turning. In one construction, known as the Hotchkiss drive, both the drive and the torque reaction were taken up on the body springs, which were securely clipped to the axle housing and directly pinned to the frame at their forward end. This construction became very popular in the United States for both passenger cars and lorries, and was successfully used even on the heavy military lorries. European designers, on the other hand, favoured the torque-tube construction for passenger cars. In this the propeller shaft was surrounded by a torque tube which was rigidly secured to the housing at the centre of the rear axle, and at its forward end had either a forked or a spherical connexion to a cross member of the frame or the rear end of the transmission case. In the United States one manufacturer after another

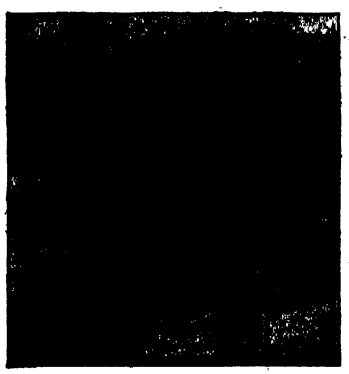

FIG. 10.—Thermoid-Hardy fabric universal joint.

adopted the plan of mounting the steering post on the left side, realizing that in a country where the "right-hand" rule of the road obtains the balance of advantages rests with the left-hand drive. Left-hand steering fits in well with brake and gear-shift levers mounted in the centre of the car, as the driver can use his right hand to operate them. In Great Britain, where the rule of the road is to "keep to the left," right-hand steering has the same advantages as left-hand steering in other countries.

Great improvements were made in hoods and wind-screens. Hoods of 1920 cars could readily be raised and lowered by a single person. The forward end of the hood usually joined up to the wind-screen supports, and by means of easily folded side curtains with transparent celluloid inserts, an open car could quickly be enclosed. Wind-screens were usually in two parts and permitted various adjustments. By setting the lower edge of the upper part slightly

forward the driver obtained a view of the road ahead through the opening between the two parts. This was a valuable feature for driving in rain, when the screen was often covered by dew which interfered with vision through it. It was known as the rain-vision effect. In Germany it became customary to provide a compartment in the body into which the hood disappeared when folded. Elsewhere a boot or cover of some rainproof material was drawn over the hood when it was folded. In the early two-part wind-screens both glasses were completely surrounded by the frames, and the frame members at the middle of the screen [illegible] fered to a certain exte[illegible] view ahead. This objectionable feature was eliminated by confining the frame to three sides of the glass. Wind-screens of this type were known as clear-vision. Extra wind-screens ahead of the rear seat were sometimes fitted.

The wheel [illegible] of the [illegible] ly of the wood [illegible] the [illegible] [illegible] [illegible]

let the customer arrange for the body with a coach-builder and select the equipment himself. After the war they showed an inclination to follow the American practice, especially with low-priced cars.

Many of the cars produced in the United States were made on what is known as the assembling plan; that is, the various major components, such as engine, clutch, gearset, axles, frame, springs and steering gear, were all manufactured in different factories by concerns specializing in these products, and were assembled into a complete car in the assembling plant. The advantages of this plan are obvious and include the possibility of intensive development of design and the economy of quantity production. The extent to which assembling was practised may be judged from the following figures: Of the American passenger-car models for 1920 92 % were fitted with stock carburetters, 75 % with stock steering gears, 66·7 % with stock clutches, 65·1 % with stock rear axles, 58·7 % with stock transmissions and 42 % with stock engines, all these stock parts being made by specialists. In the field of commercial vehicles the practice of assembling was even more prevalent.

Closed cars are favoured in countries with severe climate, and in the United States 161,000 such cars were manufactured in 1919. The most popular type among American motorists was the sedan, which seated four or more persons all in one compartment. It was therefore an owner-driver's car. The smallest type of closed car was the coupé, which has seating accommodation for two or three inside, including the driver, though sometimes a fourth seat facing backward was added. Closed cars for operation by a professional driver (chauffeur) were generally either of the town-car or limousine types; both of these seat from three to five persons inside, the difference being that the limousine has the driver's seat enclosed while on the town car it is open. Typical 1920 American designs of closed cars are shown in figs. 15–18.

An intermediate type between the motor-cycle and the full-sized car, referred to as a cycle car, had considerable vogue in Europe; it had a smaller wheel tread than the standard 56 in.; the engine in most cases was a two-cylinder of less than 100 cub. in. displacement; and the two passengers often sat tandem fashion. These cars were of the simplest design and were low in price and upkeep cost.

Motor-trucks must be equipped with engines able to take them fully loaded up the steepest grades which occur on regularly travelled highways. When operated in comparatively level districts they always have a surplus of power, and it was found advantageous under such conditions to use one or two trailers with the truck (fig. 19, Pl.). The advantage is greatest where the merchandise to be transported is very bulky. This plan results in considerable economy, as from two to three times as much load can be carried on one trip as with the truck alone, with little extra expense. In continental Europe there was usually a helper on each trailer to look after the load and apply the brakes, but the use of helpers greatly reduces the gain in economy, especially where wages are high, and in the United States it was not usual to employ an extra man. It was realized that in order to make it possible to stop in an emergency the trailers as well as the truck must be braked; but the problem of braking the trailers from the truck had not been definitely solved at the close of 1920, although at least one system of air brakes and one system of automatic mechanical brakes applied through the drawbar had been worked out. Another combination for heavy merchandise transportation consisted of a road tractor, which was merely a foreshortened truck chassis, and a semi-trailer (fig. 20, Pl.). This semi-trailer was a two-wheeled construction, the forward end of which was supported on the tractor frame by means of a swivelling fifth wheel. This end of the semi-trailer could be supported by means of jacks while loading and unloading, and the tractor did not need to stand idle while these operations were going on. A particular form of semi-trailer was the pole trailer (fig. 21, Pl.),—the length of which could be varied,—used mainly for transporting lumber, pipes, steel sections, etc.

*Commercial Development.*—Throughout the first decade of the century motor-car manufacturers in the United States either paid royalties under an alleged basic patent or else were compelled to defend themselves against charges of infringement. This patent (U.S. Patent No. 549,160 of Nov. 5 1895, issued to George B. Selden of Rochester, N.Y.; b. 1846; d. there Jan. 17, 1922) was sustained in the court of original jurisdiction in Sept. 1909, in an action against the Ford Motor Co., which had been pending since Oct. 1903. Many manufacturers had been induced to recognize the patent previous to the decision, and these constituted the membership of the Association of Licensed Automobile Manufacturers (A.L.A.M.),

which at one time comprised 90% of the industry. But during the last few years of the litigation many new firms started in business without taking out a Selden licence, and some members of the A.L.A.M. either ceased or delayed paying their royalties. The decision greatly strengthened the position of the A.L.A.M.,

FIGS. 15 to 18.—American 1920 closed-car designs (Lincoln).

and the organization of the unlicensed manufacturers, the American Motor Car Manufacturers Assn., dissolved. The Ford Motor Co., however, appealed against the decision of the lower court, and in Sept. 1911 the U.S. Circuit Court of Appeals, Second Circuit, reversed the decision. The patent was held valid but not infringed, as Selden's engine was a two-stroke, constant pressure or Brayton cycle engine, whereas the engine used by the defendant (and by practically every other motor-car manufacturer) was a four-stroke, constant volume or Otto cycle engine. The judges in their opinion said:—

"He (Selden) undoubtedly appreciated the possibility of the motor vehicle at a time when his ideas were regarded as chimerical. Had he been able to see far enough he might have taken out a patent as far-reaching as the Circuit Court held this one was. But like many another inventor, while he had a conception of the object to be accomplished, he went in the wrong direction. The Brayton engine was the leading engine of the time, and his attention was naturally drawn to its supposed advantages. He chose that type. In the light of events we can see that had he appreciated the superiority of the Otto engine and adopted that type for his combination his patent would cover the modern automobile. He made a wrong choice, and we cannot, by placing any forced construction upon the patent or by straining the doctrine of equivalents, make another choice for him at the expense of these defendants, who neither legally nor morally owe him anything."

This decision came little more than a year before the expiration of the patent, and no further effort to uphold it was made. Its name having become a misnomer, the A.L.A.M. reorganised as the National Automobile Chamber of Commerce, which came to be regarded as representative of the entire automobile industry, though the Ford Motor Co. never joined it. All of the national motor-car shows in the United States from that time till 1921 were held under its auspices, and it looked after the interests of the industry also in other ways, particularly through its legal, traffic and patent departments. Similar organizations in other countries are:—

Great Britain.—Society of Motor Manufacturers and Traders.
France.—Chambre Syndicale de l'Automobile et des Industries qui s'y rattachent.
Belgium.—Chambre Syndicale de l'Automobile.
Germany.—Verein deutscher Motorfahrzeug-Industrieller.

*Racing.*—During the years immediately preceding the World War France had the greatest export business in motor-cars, built up by consistent technical development and skilful sales propaganda, chiefly in the form of road-racing. A series of international races held during the first decade of the century, known as the Gordon Bennett Cup Races, came to an end because the French objected to the stipulation in the Deed of Gift of the cup that in the race each country should be represented by a team of three cars, which gave a country with a small industry practically the same chance of winning as a country with a large industry. In 1911 began a new series of races for the *Grand Prix* of the Automobile Club of France in which each manufacturer was allowed to enter up to three cars, and there was no limit to the number of manufacturers of any one nation. In fact, the race was not on the basis of national team against national team, but on that of manufacturer against manufacturer. This race was held four years in succession (1911–4) and was revived in 1921. Owing to the continued improvement in engines and the increased speeds made possible thereby, it was repeatedly necessary to reduce the limit on the piston displacement of competing cars. Originally the displacement was limited to that of a four-cylinder engine of 110-mm. bore and 200-mm. stroke (7·6 litres), but in 1921 the limit was 3 litres.

In England and Scotland racing on the public roads was prohibited, and the only road races in the British Isles were held in the Isle of Man. In the United States a number of important races were held in the East during the early years of the automobile movement, but owing to frequent fatalities a strong public sentiment grew up against them, and race promoters were compelled to shift the scene of their activities first to the South and then to the Middle West and the Far West. Between 1910 and 1914 a number of racing-tracks with high banking, most of them 2½ m. in circumference, were built in the United States after the model of the Brooklands track in England. The first and most successful of these was the Indianapolis Speedway. It was at first attempted to hold races on these tracks at frequent intervals, but they soon began to pall on the public. Later the plan of a single annual race was adopted, European contestants were secured and large cash prizes were offered to the winners, and from that time the Indianapolis races always had an enormous attendance. It is worthy of note, however, that practically none of the large manufacturers of America entered cars in the races held in 1919 and 1920. In earlier years competition in races was regarded as a form of sales propaganda and the expenses were charged to advertising, but the public gradually came to realize that to win a race at close to 100 m.p.h. required an entirely different car from that needed by the average family, and that it would not be safe to base conclusions regarding the quality of a company's stock cars on the performance of its special racing machines. Track-racing then became a form of entertainment, expenses being met out of gate-money.

*Shows.*—An important influence on the rapid development of the motor-vehicle industry must be ascribed to the motor-car shows held annually (except for interruptions due to the World War) in such centres as Paris, London, Brussels, New York and Chicago,

under the auspices and control of the motor-car manufacturers' associations of the respective countries. The Paris show, the oldest and for a long time the largest as regards number of exhibitors, was resumed after the war, in 1919. But in 1920 the show was suspended, because at the time when preparations would have been made trade conditions seemed to make it unnecessary. London shows were held at Olympia, and in 1920 there was an overflow exhibition at the White City. Owing to the fact that Great Britain was one of the greatest markets for motor-cars, importing more cars than any other country in Europe, the Olympia show always had a strong international flavour. There was a special show for commercial cars at Olympia in 1920, shortly before the passenger-car show. In the United States also truck shows had been held separately for several years. National motor-car manufacturers' associations previous to the World War had an international federation with headquarters in Paris. One of the activities of the federation was to allocate dates for national shows to all countries represented, so as to prevent conflict, which would have been annoying to manufacturers wishing to exhibit at several shows. The federation also endeavoured to restrict the organization of shows, to exercise a certain control over races and to influence legislation. In 1920 the original international federation was dissolved and a new allied federation took its place.

*Standardisation.*—A great help to the motor-car industry in the United States was the standardization work of the Society of Automotive Engineers, concurrent with specialization in the manufacture of parts. One of the first things standardized was fine-pitch screw threads. It was found that the former standard threads, such as the U.S.S., Whitworth, etc., were too coarse for motor-car work, and manufacturers began devising their own fine-thread standards; if this had continued it would have led to the use of many different pitches for screws of the same diameter, which would have been most annoying to the user. In order to obviate this the S.A.E. screw thread was evolved, and soon came into common use. A great deal of the standardization work was concerned with the joints or connexions between parts made in different factories. Thus the mountings on the engine, of carburetters, battery ignition units, magnetos, electric generators, starters and tire pumps were standardized, as were flywheel housings, shaft fittings, spring mountings, etc. At the end of 1920 there were about 180 separate motor-car standards on the records of the S.A.E. Great Britain had a similar technical society, the Institution of Automobile Engineers, but motor-car standardization work was carried on by a sub-committee of the British Engineering Standards Committee, on which both the Institution of Automobile Engineers and the Society of Motor Manufacturers and Traders were represented. There was also a technical society in Germany, the Automobil und Flugtechnische Gesellschaft, but it had not been active. During the World War engineering standardization work was begun in Germany by a general organization covering the whole engineering trade, and after the war motor-car standardization was continued by the Verein deutscher Motorfahrzeug-Industrieller.

*Taxation.*—In nearly all countries motor vehicles were subject to an annual road tax based upon the rated horse-power of the engine. Great Britain did not impose such a tax until Jan. 1 1921. The rate of tax was then £1 per horse-power, determined by the following equation:—

$$\text{H.P.} = \frac{Nb^2}{2{\cdot}5}$$

where N is the number of cylinders and $b$ the bore in inches. The same formula, known in Great Britain as the Royal Automobile Club formula, was used in most states of the United States, where it was known as the A.L.A.M. formula. Japan used a very similar formula, the denominator of the fraction being 3 instead of 2·5. Widely different formulas were in use in different countries for determining the tax horse-power. Some, like those above cited, made the horse-power proportional to the cylinder bore, others to the piston displacement volume, and still others to this volume and the normal speed of revolution. Let C be a constant, $b$ the cylinder bore, $l$ the piston stroke, N the number of cylinders, and $r$ the normal engine speed—then the various horse-power formulas used in 1920 may be written as follows:—

For Belgium: $\text{H.P.} = C.b^2.l.N.r$ (where C varies between 3 and 3·5 for motor-cycles and between 4·5 and 5 for motor-cars, and $b$ and $l$ are in metres. It was customary to make C = 3 and $r$ = 1,000 for motor-cycles and C = 4·5 and $r$ = 1,000 for motor-cars).

In France the formula reads the same as that for Belgium; C is equal to 0·0002 for single-cylinder engines, 0·00017 for two-cylinder, 0·00015 for four-cylinder, and 0·00013 for multi-cylinder. $b$ is inserted in centimetres, $l$ in metres, and $r$ in revolutions per second.

In Germany: $\text{H.P.} = 0{\cdot}3N.b^2.l$ ($b$ being in centimetres and $l$ in metres). Holland, Denmark, Switzerland and Russia used the same formula.

In Italy: $\text{H.P.} = 0{\cdot}0525N.b^2$ for passenger vehicles and $\text{H.P.} = 0{\cdot}0350\ N.b^2$ for commercial vehicles ($b$ being in centimetres).

*Ford Cars.*—A unique position in the American motor-car industry has been occupied by the Ford Motor Co., whose annual production for several years constituted about one-half that of the whole industry. This company in 1909 succeeded in developing a passenger car which it was able to sell for the next 11 years without material modifications in design except as regards the body and equipment. This stability of design made possible production on an unequalled scale and at remarkably low cost. At one time during the World War period this car sold in the United States as low as $325 for the two-seater and $360 for the five-seater. In 1917 the company began to produce also a light truck, and in 1920 the production of passenger cars and trucks combined exceeded 1,000,000 vehicles.

*German Lorries.*—Motor-lorry services under public ownership were developed in Germany after the Armistice of Nov. 1918 from an emergency service previously established by the War Department. Toward the end of 1916 the German Government, facing a transportation crisis at home, was compelled to withdraw a large number of motor lorries from the front in order to relieve the congestion at freight depots and to carry agricultural produce to the great centres of population. This service was gradually extended, and during the last full month of the war, Oct. 1918, the lorries in the home service moved 302,000 tons of freight and covered an aggregate distance of 922,000 m., of which 525,000 m. was with load. The useful work done amounted to 1,960,000 ton-miles and the fuel consumed to 266,666 imp. gallons. After the Armistice 16 limited liability corporations (*Kraftverkehrsgesellschaften*) were organized, and operating territories were assigned to each so that the whole country was covered. The National Government furnished the vehicles and received in return shares of stock and certificates of indebtedness. Most of the capital stock of the companies was subscribed by the local governments of the districts served. According to a report made in 1920 these companies then operated 98 services with a rolling-stock consisting of 2,871 motor lorries, 37 tractors, 1,079 trailers, 187 passenger cars, 126 motor-cycles and 150 motor-buses. The personnel numbered 3,000. The interests of the national Government in these companies were looked after by the Treasury Department. Lorries and other vehicles with drivers (and helpers if necessary) were furnished either on a direct ton-mile basis or by the day, in the latter case there being a limit on both the time and the distance covered, with extra rates if either limit was exceeded. Similar services for passengers and mails were established in Germany by the Post-Office Department. In 1920 this department established 100 new mail lines in country districts with an initial equipment of 260 vehicles; it also added between 400 and 500 vehicles to the equipment for carrying mails in the cities.

*Motor Omnibuses.*—The largest motor-omnibus service in the world in 1920 was that of the London General Omnibus Co., which then had more than 2,500 buses in operation. This company shortly after the World War introduced a new "K" type of double-deck omnibus with seating capacity for 46 passengers (22 below and 24 on top), which weighed no more than the 34-passenger buses in service up to that time (see fig. 26, Pl.). Of the passengers carried on the lower deck six occupied a longitudinal seat while all the rest faced forward. The chassis frame and the framework of the body of this new omnibus were made of ash bars reinforced with steel flitch plates. Practically all the panels of the body consisted of three-ply birch; the main floor was of the same material and had wearing slats secured to it, while the roof consisted of two thicknesses of this three-ply with a layer of waterproof duck between. Fully equipped for service this motor omnibus weighed 7,600 lb., of which 2,350 lb. was body weight. The engine had four cylinders of 100-mm. bore and 140-mm. stroke, which were cast in pairs; it developed 30 H.P. at 1,050 r.p.m. The wheelbase was 170½ in.; the large passenger capacity for this wheelbase was made possible by placing the driver's seat alongside the engine. On July 1 1920 there were 80 of these buses in service.

*War Developments.*—During the World War the motor-car industries of all the belligerent countries greatly increased their productive capacities, because they possessed the personnel and the equipment necessary for turning out many essentials of warfare, such as vehicles of all kinds, aero-motors and munitions. Thus the capitalization of the German motor industry increased about 180% between 1914 and 1919. Twenty German motor-car manufacturing concerns during this period issued additional stock to the amount of 176,350,000 marks, and bond issues and the capitalization of newly organized companies brought the capital increase up to 214,950,000 marks. There was a similar increase in the capitalization of the British motor-car industry, but most of the new issues of stock in Great Britain occurred after the Armistice, while in Germany the greatest accession of new capital took place during the war period.

During the early part of the World War the American motor industry furnished large numbers of motor lorries to the British, French and Russian Governments, and this was reflected by the export returns, which showed an increase in the number of trucks exported from 784 in 1914 to 21,265 in 1916. At the same time the foreign demand for American passenger cars increased greatly, because the belligerent European countries could not make deliveries. In 1918, when the United States threw its full

strength into the war; motor-car exports suffered a material decline, but they jumped ahead again immediately after the Armistice, an increase of 79% being shown in 1919. That year the exports of passenger cars, lorries and parts together exceeded $100,000,000 in value, yet the passenger cars exported were hardly 4% of the total production, while the exports of commercial vehicles amounted to 4.9 per cent.

After the war the tide of international motor-car commerce showed great fluctuations. As soon as shipping connexions became reëstablished there was a heavy demand, particularly in the neutral countries of northern Europe. In 1919 only the United States was in a position to export large numbers of vehicles, because it took the motor-car industries of the European belligerents a long time to get back to a peace basis. After a short time, however, the low rates of continental exchange and temporary embargoes on motor-car imports in several countries, including Great Britain, France, Germany, Italy, Denmark and Norway, cut down the exports from the United States. Even when the embargoes were lifted imports were restricted by high customs duties, as, for instance, 70% in the case of France.

*Electric Cars.*—There was little progress in electric vehicles during the decade 1910-20. The electric is essentially a town car, and during the first half of the decade a good many electric passenger vehicles were in use, especially in four of the larger cities of the United States; Buffalo, Cleveland, Chicago and Los Angeles, all of which are comparatively level and have fine boulevard systems. The electric appealed particularly to lady drivers, because it dispensed with the cranking of the petrol car and was generally simpler and less troublesome to operate. With the advent of the electric motor starter this disadvantage of the petrol car largely disappeared. The introduction of demountable rims and power tire pumps further reduced the hard work in connexion with the operation of petrol cars as compared with solid-tired electric vehicles. The electric then became more and more a luxury vehicle, built only in expensive closed-body types and used mainly for town driving by people who owned a petrol car for country driving in addition. The electric commercial vehicle industry also was more or less stationary while the petrol commercial industry forged ahead rapidly. In 1920 the electric lorries in service in New York City formed a small portion of all the commercial vehicles, which was not the case in 1910. A new type of electric commercial vehicle, known in the United States as an industrial truck, but perhaps better described as a floor truck or a low wheel truck, came into extensive use, especially during the war period. These industrial trucks take the place of hand trucks on steamship piers and railway station platforms, in factory buildings and paved yards. Petrol industrial trucks have also been developed, but as they are not admitted to steamship piers on account of the fire hazards the electric has an undisputed field there. There was great inducement in Europe during the war, when petrol was exceedingly scarce, to develop the electric vehicle for both passenger and commercial traffic. In Germany a scheme was worked out for a system of goods transport in large cities by electric lorries with interchangeable batteries, and a few sample trucks were built, but the Armistice intervened and the scheme was dropped. The steam vehicle also retrogressed as a factor in transportation. In 1920 there was only a single concern in all the world making steam-propelled passenger cars in any considerable numbers, the Stanley Motor Carriage Co. of Newton, Mass., which was one of the pioneers in this line of industry. Considerable numbers of steam lorries were still being manufactured in England, but the steam motor-buses at one time in service in London had been taken off the streets. The petrol motor had definitely gained the ascendency over steam and electric motors, and supplies for it could be found and repairs to it had in almost every town. In the United States, for instance, there were, at the beginning of 1920, 43,643 repair shops (besides 36,227 garages), and all of these repair shops were equipped to cater to owners of petrol cars, but only a few to owners of steam and electric vehicles, giving a tremendous advantage to the former.

**MOTTL, FELIX** (1856–1911), German conductor (*see* 18.931*), died July 1 1911.

**MOULE, HANDLEY CARR GLYN** (1841–1920), English divine, was born at Dorchester Dec. 23 1841, the youngest son of the Rev. H. Moule, vicar of Fordington, Dorchester, a prominent Evangelical clergyman. He was educated at home, and later at Trinity College, Cambridge, where J. B. Lightfoot was his tutor. He was bracketed second classic in 1864, and in 1866 obtained a first-class in theology. From 1865 to 1867 he was an assistant master at Marlborough, and after a few years of a country curacy became dean of Trinity College (1873–6). In 1880 his position as a prominent Evangelical was recognized by his election as first principal of Ridley Hall, Cambridge, an establishment founded for post-graduate training for the ministry. Moule's influence in this position was very great, and he considerably widened his influence by the production of various religious works of a popular kind, among them being *Thoughts on Christian Sanctity* (1886) and *The Secret of the Presence* (1901). He also published a *Commentary on the Epistle to the Romans* (1880) and *Outlines of Christian Doctrine* (1889). In 1899 Moule, who in 1898 had been made an hon. chaplain to Queen Victoria, was elected to the Norrisian professorship of divinity at Cambridge, but in 1901 he was chosen to succeed Westcott in the bishopric of Durham. He died at Cambridge May 8 1920.

His brothers, ARTHUR EVANS MOULE (1836–1918) and GEORGE EVANS MOULE (1828–1912), were both well known as missionaries in China, the former becoming archdeacon of Mid-China in 1881, and the latter the first bishop of Mid-China (1880–1908).

**MOULTON, JOHN FLETCHER MOULTON,** BARON (1844–1921), English judge, was born at Madeley, Salop, Nov. 1 1844. He was educated at New Kingswood school, Bath, and St. John's College, Cambridge, where he had a brilliant career, becoming in 1868 senior wrangler and first Smith's prizeman. Until 1873 he was a fellow of Christ's College, but in that year he came to London, and in 1874 was called to the bar. He became a Q.C. in 1885, and the same year entered Parliament as Liberal member for the Clapham division. He lost his seat in 1886, but from 1894 to 1895 sat for South Hackney and from 1898 to 1906 for the Launceston division of Cornwall. Fletcher Moulton earned a great reputation not only as a sound and skilful lawyer, but also as a mathematician and experimental chemist of a high order. He was retained as counsel in many important cases, e.g. [illegible] of patent law, in which such special knowledge was necessary, and he was one of the first lawyers to perceive the enormous importance which chemistry was likely to assume in relation to various aspects of the law. He was raised to the bench of the Court of Appeal in 1906, being knighted and sworn of the Privy Council, and in 1912 was made a lord of appeal and a life peer, being also appointed to the Judicial Committee of the Privy Council. Lord Moulton's career as a judge was unfortunately marred by a painful family litigation against him. In 1875 he had married Mrs. Thomson, of Edinburgh, who already had a family of two sons and two daughters. She died in 1888, and in 1901 Lord Moulton married again. In 1902 his step-daughters, who had continued to live with him, took proceedings against him with reference to the manner in which the income to which they were entitled under their mother's will had been expended in connexion with the household expenses. The court eventually gave judgment in their favour, after a good deal of scandal had been made over the affair. Lord Moulton became a member of many important legal and scientific committees, being appointed first chairman of the Medical Research Committee under the National Insurance Act (1912). On the outbreak of the World War in 1914 he became chairman of the Committees on Chemical Products and on High Explosives, and the same year was made director-general of explosive supplies in the Ministry of Munitions. In 1915 he was made a K.C.B. and in 1917 a G.B.E. It would be difficult to exaggerate the value of his work for the Government as a scientific adviser during the war, and in stimulating the industrial developments for the production of explosives, a chemical question involving, *inter alia*, the reorganization of the British dyeing industry. In this connexion he acted as chairman of the British Dyestuffs Corporation (*see* DYEING) when it was created in 1919; and his labours were actively continued after the war ended. He died suddenly in London March 9 1921, leaving one son by his first marriage, Hugh Lawrence.

**MOUNET-SULLY, JEAN** (1841–1916), French actor (*see* 18.936), died in Paris March 1 1916.

See his *Souvenirs d'un Tragédien* (1917).

**MOUNTED TROOPS** (*see* 5.563; 18.939).—Under the term "Mounted Troops" is here included, in the modern text-book senses: (*a*) *Cavalry*, mounted on horses and able to fight either mounted or on foot; (*b*) *Mounted rifles*, whose characteristics and methods are the same as those of cavalry, except that they are not equipped for mounted combat; (*c*) *Mounted infantry*, denoting infantry carried on horses or camels, employing infantry formations when dismounted, and probably insufficiently trained to perform satisfactorily cavalry duties such as reconnaissance; and (*d*) Cyclists.

In recent years the trend of cavalry ideas has, as regards tactics, undergone very considerable change. In the South African War of 1899–1902 hardly any instances of shock action by cavalry were seen; and in the years immediately following it a large body of military opinion in England was in favour of relinquishing altogether the idea of charging home with the sword or lance. This opinion was strengthened by the events of the Russo-Japanese War. A little later it was realised that the absence of shock action in S. Africa was due not so much to the power of the rifle and machine-gun as to the peculiar tactics of the Boers, who seldom stood their ground to await the British attack; it was found that, while instances of successful cavalry charges were rare, there was no case in which a mounted attack was prevented by fire from reaching its objective. It was further seen that in Manchuria the nature of the country, and the quality of the mounted troops engaged alike were inimical to successful cavalry action.

The pendulum of opinion now swung in the direction of shock action, and for a year or two the training of the British cavalry showed a distinct bias in favour of the *arme blanche*. From 1909 onwards, however, thanks to the influence of, amongst others, Sir John French, Sir Douglas Haig, and Maj.-Gen. Allenby, the correct balance was struck between fire and shock, and ideas were crystallised into definite, well-understood principles. As the result it may fairly be claimed that, when the World War broke out in 1914, no more highly trained body of troops existed

in Europe than the British cavalry. The German cavalry gave the impression of having lost their confidence in the *arme blanche* without having become fully proficient in the tactics of the dismounted attack. The French and Austrian cavalry, on the other hand, probably still relied too much on the *arme blanche*.

At the outbreak of the World War the theory of the employment of cavalry was governed by the following broad principles. (1) Before the battle, cavalry locate the enemy by reconnaissance, screen their own infantry from the enemy's observation, and protect them from interference while marching to the battlefield. (2) During the battle they are posted far out, protecting the flanks; act as a mobile reserve, ready to move quickly to fill a gap in the line or confirm a success; and occasionally intervene in the conflict by attacking the enemy on an unprotected flank. (3) After a successful battle they pursue the retreating enemy, effecting captures and preventing him from recovering himself, or, if they are unable to do these things, providing early information of his dispositions in the next line which he takes up. (4) After an unsuccessful battle they cover the retirement of the infantry, giving them time to recover their *moral* and to reach the next position which they mean to hold.

In order to provide for the above duties cavalry were formed into three groups:—(1) *Independent*, for long-distance reconnaissance and for other missions in which cavalry might be employed independently of the rest of the army; (2) *Protective*, for the duty of screening the main infantry columns; (3) *Corps* or *Divisional*, for minor reconnaissances, and for intercommunication and orderly duties inside the infantry columns.

These groups were intended to be elastic in their composition, and it was correctly foreseen that the requirements of different phases of the campaign or action would often necessitate one group being reinforced at the expense of another. While it was realized that infantry commanders must have some mounted men for their own immediate needs, it was a principle that the minimum number should be allotted to group (3), the bulk being kept as independent or protective cavalry. The reason underlying the division into the two last-named groups was the advisability of separating reconnaissance from protection.

It may be affirmed at once that the above subdivision of cavalry duties still held good in 1921, and that the separation of the duties of reconnaissance and protection is a principle which should underlie the employment of all cavalry bodies.

A reconnoitring detachment, having been asked certain questions, should be free to move in any direction in order to find the answers; moreover, touch with the enemy, once it has been established, should not be relinquished. Protection, on the other hand, entails the detachment regulating its movements to some extent by those of the force which it covers. It follows that, if one detachment is entrusted with a rôle which includes both these duties, the efficient performance of one or the other of them is likely to suffer.

*Cavalry in the World War.*—If the events of the World War in the various theatres are studied, and if it is remembered that the whole of the campaign in Flanders and northern France, as well as much of those in Russia and Italy, was really one huge battle with flanks non-existent, it will be found that cavalry were constantly called upon to fulfil each and all of the rôles mentioned above. For instance, during the advance into Belgium before the battle of Mons, the British cavalry moved well in advance of the infantry. The latter were thus enabled to reach their battle positions unmolested, and without the extra fatigue of having to deploy for a fight; the cavalry meanwhile had numerous minor skirmishes with the German cavalry, who were fulfilling a similar rôle, but were unable to penetrate the British screen.[1] The plans for the battle of Beersheba in 1917 and those for the final advance in Mesopotamia in 1918 were based very largely on the result of cavalry reconnaissance, in spite of the fact that air reconnaissance had by this time made great strides.

[1] It seems, indeed, probable that when von Kluck issued his orders for the battle of Mons he was very much in the dark as to the position of the British left flank.

As regards participation in the actual battle, at Mons and Le Cateau the bulk of the British cavalry were posted to the west of the infantry, where they were able to frustrate the German efforts at outflanking. After the fall of Beersheba too, while Sir Philip Chetwode's infantry were wheeling to their left in preparation for the next phase of the operations against the left of the main Turkish position, the mounted troops, placed several miles away to the right, were able to protect the flank of the wheel by defeating several determined counter-attacks. Cavalry used in this way can provide ampler elbow-room for manœuvre than less mobile troops because they can be sent with safety to greater distances.

Of the value of cavalry in battle as a mobile reserve many striking illustrations can be found in the stories of the first and second battles of Ypres and of the German offensive in 1918 on the Somme. On many occasions in these operations they relieved infantry who had been exhausted or practically annihilated by continual heavy fighting; on others, by counter-attacking or by filling a gap defensively, they reëstablished the connexion between infantry formations which had drawn apart. In this respect it should be noted that, while the tactical disadvantages of a gap in the line are of course obvious, only those who have had actual war experience can realize the quite disproportionate moral effect on everyone, from the general to the private, of losing touch with the units or individuals on the right and left. Sir Douglas Haig, in his despatch dealing with the German offensive in 1918, writes as follows: "Without the assistance of mounted troops, skilfully handled and gallantly led, the enemy could scarcely have been prevented from breaking through the long and thinly held front of broken and wooded ground before the French reinforcements had had time to arrive." These words, it may be remarked, refer to a period when tanks were already present in France in fairly plentiful numbers.

It is well to remember that the value of a reserve depends chiefly upon its freshness, and that even where conditions of ground or traffic preclude cavalry, as will often be the case, from moving much faster than infantry, they will invariably arrive on the scene of action less tired. A good illustration of this occurred in the Somme battle of 1916, when two cavalry regiments were ordered to fill the gap between an infantry division which was fighting in Longueval and another which was being launched from reserve against High Wood. The infantry had to advance a few miles only, but the day was a hot one and the shelling heavy. On reaching High Wood they were so exhausted that all efforts to make them dig themselves in were unavailing. The cavalry, owing to the maze of trenches and wire, could not move even as fast as the infantry, but they dug themselves in with such vigour that by the following morning they were completely underground. Nor must it be forgotten that *moral* is largely a question of physical fatigue.

The most brilliant rôle which can be allotted to cavalry in battle is that of intervention on an unprotected flank, or on a flank so weakly protected that the cavalry find themselves in great superiority. In the war on the western front no examples occurred of this, for the simple reason that unprotected flanks of sufficient length to give mounted troops the scope they require did not exist. A possible exception is the German break-through in the spring of 1918, but by this time the bulk of the German cavalry had been dismounted. In the more open theatres of the war, however, such as Palestine and Mesopotamia, cavalry often intervened in the battle with very important results. At the action of El Mughar in Palestine in 1917 a yeomanry brigade charged successfully the flank of a position which was holding up an infantry division, and took upwards of a thousand prisoners. Ramadi, in Mesopotamia, in the same year provides an instance of an entirely unprotected flank which enabled the cavalry to place themselves directly across the enemy's only line of retreat. The Turks, after attempting to break out through the cavalry under cover of darkness, surrendered next morning, and a force of 3,500 was thus destroyed. Examples such as these, and several more like them could be given from the campaigns of Mesopotamia and Palestine, show that the value of

cavalry on the battle-field can still be decisive, given the right conditions. These conditions are: (*a*) a theatre of war whose size, in relation to the numbers of troops engaged, admits of wide, open spaces; (*b*) an enemy who, by reason of inferior numbers, skill, or organization, cannot protect his flanks effectively.

There is no reason to suppose that such conditions will not be met with in the future, even in a European war, as often as those obtaining on the western front from 1914–8; and as regards a war outside Europe, they are typical of the campaigns which have been fought in the past, and which will assuredly be fought again. Still, it cannot be denied that, for the cavalry of Europe at any rate, the size of modern armies and the general use of entrenchments, especially barbed wire, have decreased the chances of distinction in battle, already much reduced by the greater power of missile weapons.

The best example of the part which can be played by cavalry after a successful battle is that of Gen. Allenby's victory in Palestine in 1918. The enemy's flank having been rolled up by means of an infantry attack in great strength near the coast, the Desert Mounted Corps, consisting of three divisions, passed through. After riding due north for about 35 m., mopping up prisoners as they went, they turned north-east over the mountains, where they were just in time to forestall a hostile infantry detachment which was being hurried forward to defend the pass, and debouched at dawn into the Plain of Esdraelon. By five o'clock in the evening of the day after the battle these divisions had marched 70 m. in 36 hours, and had placed themselves completely across the Turkish lines of communication. As a result 40,000 prisoners fell into their hands. The remnants of the Turkish army, retreating northwards, were pursued and overtaken. Damascus and Aleppo were successively occupied by the mounted troops, though not without fighting, and the Desert Mounted Troops took altogether 75,000 prisoners out of a total Turkish ration strength of about 100,000. The division which took Aleppo marched 500 m. in five weeks.

Other instances of successful cavalry pursuits during the World War could be found from the campaigns in Russia and Mesopotamia, and that in Palestine in 1917. And, referring to the end of the war in France, Sir Douglas Haig wrote as follows in his final despatch: "On the morning of the Armistice two British cavalry divisions were on the march east of the Scheldt, and before the orders to stop reached them they had already gained a line 10 m. in front of our infantry outposts. There is no doubt that, had the advance of the cavalry been allowed to continue, the enemy's disorganized retreat would have been turned into a rout." The events of the war in all theatres show clearly enough that a retiring force can march more quickly than one which is advancing and that only a comparatively brief respite is required to enable a beaten force to recover itself. It follows that a force of superior mobility is essential if the fruits of victory are to be gathered and a long succession of pitched battles avoided.

As for pursuit, so also for retreat, the value of cavalry was proved many times in the Russian campaigns. But a good instance is provided by the retreat of the British Expeditionary Force from Mons in 1914. During every day of this operation the British cavalry interposed themselves between the main columns of the army and the pursuing Germans, and so saved the infantry many tiresome rearguard actions and much fatigue. But from the point of view of *moral*, the services rendered by the cavalry were perhaps even more important. Some idea will be gained of them if it is remembered, once again, that the horse soldier is almost invariably less tired, and consequently less prone to doubts and fears, than the foot soldier, and that he sees over every hedge while the infantryman has to peer through it. Even so, it is difficult for any but an eye-witness to realize the extent to which the infantryman relies on the protection afforded him by the cavalry, the anxiety with which he awaits news, and the relief with which he receives it from his mounted brother, riding past in the dark, on his way to billets.

*Future Organisation.*—Before considering what influence modern inventions are likely to have on the future of mounted troops, it will be well to clear the ground by pointing out the advantages and disadvantages for war of cyclists as compared with horse soldiers. Their chief advantage is that every man can go into the firing line, whereas one horse soldier out of every four has to remain behind to hold the horses. On really good roads in good weather they can move more quickly than horses; and no supply column is required to feed bicycles. On the other hand, they are completely tied to roads, and if the men leave the roads to fight, they must eventually come back to the place where they left their bicycles, which cannot be brought up to them. Cavalry are preferable to cyclists for fighting purposes in all country except that which is so enclosed that horses also are almost confined to roads. And even then the roads must be specially good for cyclists to justify themselves. On the cobblestone roads which are so common in Flanders and northern France, and in other parts of Europe, the pace of cyclists is, in wet weather, reduced almost to that of a walking man. In fact there seems to be no country except Great Britain where they would advantageously take the place of horse soldiers for fighting purposes. For purposes of intercommunication, however, they are extremely valuable, and the attachment of cyclists to an infantry unit will save much expenditure of horseflesh in any country reasonably well provided with roads. That is to say, they can take the place of part of the divisional cavalry. As a rule they should not be attached to the larger cavalry formations. They will often have to move by a different route to that most suitable for cavalry, and, if marching in a column, discomfort results from the fact that their pace is much altered by gradients which are hardly perceived by horses; consequently the saving of horseflesh does not compensate for the extra trouble and complication of orders. But motor cyclists are of incalculable value with cavalry, and will be still more when a machine is produced which can move across country.

The modern invention which, more than anything else, limited the activities of cavalry in the World War was barbed wire. It is doubtful whether this will be the case in the future. Barbed-wire entanglements are an accompaniment of position warfare; it takes much time and much man-power to erect them and this must always be the case except in the unlikely event of some invention arriving which will enable the soldier to produce barbed wire much in the way that the conjurer emits yards of coloured paper from his mouth. Besides, in view of the introduction of the tank and the development of the wire-cutting technique of artillery it is questionable whether barbed wire will ever again play the part which it fulfilled in 1914–17.

The developments most likely to influence the future of the mounted arm are: (1) the tank; (2) the cross-country tractor; (3) the aeroplane; (4) gas.

The tank is thought by some to be likely before long to oust cavalry entirely from warfare, and the views of these persons, though they may be extremists, are entitled to very respectful consideration. They claim, and claim justly, that the evolution of the tank has made very great strides since the signing of the Armistice; and they assert that it will advance nearly as quickly in the future, a statement which is more open to argument. Experimenting with a new arm is a costly process, and, besides, the tank is not a vehicle which can be easily adapted for civil use in times of peace. The paramount question of expense therefore, coupled with the absence of the stimulus of actual or impending war, is likely to slow down the development of tanks, as well as the provision of them in large numbers.

The latest type of tank can, it is understood, go as fast and as far as cavalry in all but very unfavourable country; but it may be a number of years before a machine is produced which is capable of crossing swamps, thick woods, or rocky mountains, and which is thoroughly satisfactory in a tropical climate. It is true that obstacles of this kind affect cavalry also, but tracks invariably exist by which they can surmount them, though they may have to go in single file at a foot pace. And it would be specially dangerous for the British army entirely to replace cavalry by tanks, because conditions unfavourable to tanks are precisely those with which it has most often to contend.

Nor would it be safe to rely upon the vulnerability of the tank remaining as low as at present. The history of military invention shows us that the missile and the protection against it alternately obtain the mastery. At present, so far as the tank is concerned, the latter is in the ascendent, but the study of anti-tank methods has hardly been begun. A metal machine, which is as conspicuous as the tank, presents certain very weak points of attack to modern science, with electricity, magnetism, and automatic ranging at its command. It may confidently be asserted that in the future anti-tank methods will develop more quickly than the tank itself; but it must also be pointed out that they have much leeway to make up.

Apart from the above question of development the tank possesses an inherent disadvantage in that the force which it represents is very highly concentrated. Tanks will not be able to hold positions even if they take them. For at night or in fog an enemy, if he chooses to attack in great superiority, will get through any line which is not held continuously by men stationed almost at arm's length from one another. The essence of success, for this reason, lies in the concentration of superior man-power at the decisive point; and in the future, as in the past, the rôle of all arms other than infantry and cavalry will be the subsidiary one of facilitating that operation. In the actual attack, too, a lucky shot, putting a tank out of action, destroys a much larger proportion of the force than would the same shot striking the equivalent body of cavalry, which would be dispersed. This disadvantage of over-concentration, aggravated as it is by the conspicuous character of the tank, will not disappear until a machine is produced which provides complete protection for single men, and so allows of dispersion; and this is an event which is very far distant.

Nevertheless, where an attack on trenches is concerned, and especially on those protected by wire, the tank is immeasurably superior to cavalry. In war it will often fall to the lot of cavalry formations to make such an attack, and it is here that tanks may well replace a part of the cavalry, the remainder being employed in assailing the weaker parts of the enemy's front, in holding the position when taken, and in rounding up fugitives, for which again dispersion is necessary. In the World War armoured cars were often used with success for conveying special officers from place to place under fire, and for early-morning reconnaissance, when it was desired simply to locate an enemy with whom touch had been temporarily lost. In the next war fast tanks will replace the armoured car for these purposes. But for the more detailed reconnaissance which usually follows, armoured cars, and tanks also, are unsuitable, by reason of their vulnerability when stationary and the limited range of vision which is obtainable from inside them. In the future them, tanks will not usurp the functions of mounted troops, but on the contrary will widen their scope by relieving them from the necessity of attacking, or of waiting for infantry to attack, organised positions. A force of tanks, fully as mobile in every respect as the horse, will be attached to all higher cavalry formations.

The influence of the second new development, the cross-country tractor, will be wholly in favour of mounted troops. In the past one of the chief obstacles to the employment of cavalry has been the difficulty of supplying them, and the length of road space which the subsidiaries, artillery, engineers, and rearward services, take up. This probably is one of the reasons for the German cavalry showing up so little during the retreat from Mons, and for this not being employed at all to confirm the success gained in March 1918, when according to Sir Douglas Haig, "their presence could not have failed to have added greatly to the difficulties of our task." Cross-country tractors, independent of roads, carrying supplies of all sorts, and perhaps dragging the guns, will greatly enlarge the radius of action.

Of all novelties in warlike organisation, the aeroplane is the most serious rival to cavalry. It has already taken over to a great extent the duties of reconnaissance which were formerly performed almost exclusively by mounted troops. The service of discovering the direction of the enemy's principal concentrations, whether by road or by rail, and of reporting upon his entrenchments, gun positions, and larger activities generally, is now carried out from the air. This was formerly the province of the independent cavalry, which was consequently made as strong as possible. Now, owing to the advent of the aeroplane, the proportion of cavalry allotted to independent work will be relatively smaller, except in the case of a pursuit, and the bulk of the horse soldiers will be employed on missions which are protective in character. It must not be supposed, however, that the service of reconnaissance can be carried out entirely from the air. It is difficult for aeroplanes to observe lesser details or to distinguish between friend and foe; for, if they fly so high as to be invulnerable from the ground, they can distinguish nothing but heavy columns or clearly marked entrenchments and tracks; at medium heights they were, even at the close of the late war, fairly vulnerable to anti-aircraft weapons, which are likely to improve in efficiency in the future; and at low altitudes again the very speed which protects them from anti-aircraft fire militates also against accurate observation. Therefore, for the service of reconnaissance, cavalry will still be required to supplement aircraft reports; to provide, especially in open warfare where clearly marked trenches do not exist, detailed information as to the enemy's dispositions; to secure identifications by the capture of prisoners; and, above all, to replace the aeroplane under conditions of ground or climate which are unfavourable to air reconnaissance. In this connexion it may be mentioned that, during stationary warfare in the summer of 1918 in the Jordan valley, the very efficient Air Force units attached to the Egyptian Expeditionary Force were found to be of comparatively little value for purposes of tactical reconnaissance. The ground, precipitous, rocky, and very complicated, cast deep shadows in every direction; and in the middle of the day atmospheric conditions over the deep trough of the valley made flying almost prohibitively dangerous.

A matter for much more serious consideration by cavalrymen is the question of attack from the air. Towards the end of the war in France it became clear that troops whose location is not completely hidden are liable to be bombed at any time by day or by night, and, further, that even a superior air force is powerless to prevent such attacks. Much can of course be done by attacking the enemy's aerodromes, but the great radius of action of aircraft increases so much the value of the initiative that it is hopeless to expect, however great the superiority, to get command of the air in the sense that it can be obtained by land or sea. And it is next to impossible to conceal the presence of a large number of horses. Led horses will, of course, be specially vulnerable. Given great superiority in aircraft, it may be feasible to provide protection by having some machines continually overhead. By day this might prove adequate, though it would entail a very great strain on the resources of the Air Force. By night it would be of little value. The true defence against aircraft, other than that of carrying the war into the enemy's country and attacking his aerodromes, is from the ground, and it must be admitted that, against an enemy with an efficient and enterprising air force, the existence in war of mounted troops will become precarious unless a great advance is made in the science of anti-aircraft defence from the ground. They must be prepared, in any case, to deliver their blow from widely separated formations, instead of massing for attack. Means of intercommunication must therefore be very specially studied and developed. It should be noted that, in the case of tanks also, the difficulty of concealment from the air will be great if they are employed in large numbers, but here it may be possible to devise some sort of portable and easily erected covering, which will provide at the same time camouflage and overhead protection. Gas attacks will be particularly dangerous to mounted troops because, though horses are less affected by gas than human beings, it is very much harder, if not impossible, to devise for them an efficient protection against it. However, it is doubtful whether gas will ever become an important factor in mobile warfare, and mounted troops can move comparatively quickly out of a gas area.

The division of mounted troops into three groups—independent, protective, and corps or divisional—has already been explained. The corps or divisional group will consist, in every suitable country, partly of cyclists and partly of mounted men; it will have attached to it a few motor-cyclists and a few light and very fast tanks. These latter would correspond to the present-day armoured car but would be able to move off the roads. They would be used principally for what may be called first reconnaissance purposes, to save horseflesh. Owing to the advent of the aeroplane, the independent group will be smaller, during most of the stages of a war, than formerly was thought likely, but mobile land forces will still be required for detailed reconnaissances and other independent missions.

The composition of the independent and protective groups will be governed by the same principles, since their duties are interchangeable at any time. For both groups, a highly mobile mixed force is required, the ingredients of which will vary in their proportion to one another according to the characteristics of the enemy, the nature of the theatre of war, and the climate. In the different echelons of the ammunition, supply, and medical services the replacement should be aimed at of all horse transport by cross-country mechanical tractors, which might also carry drinking-water for men, if not for horses; the heavier guns too might be drawn by mechanical means. To a division of cavalry at least two squadrons of aeroplanes should be allotted, one for protection against hostile aircraft, and one for coöperating in an attack and for carrying out local reconnaissances required by the cavalry commander for his own information. In certain conditions the use of aeroplanes for supply is most desirable, but machines need not normally be attached to cavalry for this purpose. For intercommunication a liberal supply is needed of motor-cycles, capable if possible of moving across country. Light and fast tanks will be required, in small numbers only, for the reconnaissance purposes already indicated in the case of the corps or divisional mounted troops. Tanks, possessing heavier armour and ordnance—but at least as mobile as the cavalry, will break down lanes through the enemy's wire entanglements and trenches, will increase his disorganization and render him ripe for a cavalry attack, and will crush his resistance where he is still holding out. In a word, where cavalry formerly had to wait for the infantry to come up and provide weight for an attack, the coöperation of tanks will now enable them to press forward at once. Though it is extremely dangerous to dogmatize regarding numbers, the proportion of tanks to cavalry should, in a civilized country against a well-organized enemy, perhaps be as much as two to a squadron, or 54 in a division of nine regiments.

In every case the backbone of the mobile force will still consist of horse soldiers, because they alone of mobile troops can provide the dispersion which is necessary to hold a position or to carry out certain other operations of war, such as the policing of a country in insurrection, the pursuit of an enemy, or the hand-to-hand conflict which is the ultimate object of all battles; and because also, in certain conditions of climate or ground, they alone will retain their mobility. For this latter reason also, part of the artillery should be horse-drawn.

*Future Tactics and Training.*—Before the World War the principles which have already been enunciated held good in all European armies regarding the employment of mounted troops. It was therefore thought probable that in most cases they would come into conflict with, and have to beat, the hostile mounted troops, before being in a position to fulfil their rôle. Further, because both sides would be anxious to waste as little time as possible, it was considered likely that this first conflict between the opposing cavalries would, at least as often as not, take the form of a mounted collision. Neither of these conclusions was justified by the events in the western theatre, in Palestine or in Mesopotamia. The Turkish mounted troops were few in number and despicable in efficiency; the Germans in France and Belgium failed to make much use of their cavalry even during the retreat from Mons. Consequently, so far at least as these three campaigns are concerned, conflicts between mounted troops were somewhat rare. And even when they did occur no mounted collision took place, except in a few instances when very small numbers were engaged. It is thought that, in the future also, mounted collisions will be uncommon, and for the following reasons. Every battle, whatever arm is taking part, resolves itself into a series of minor engagements, in each of which one side is on the offensive and the other on the defensive. It never happens, in these subsidiary fights, that both sides are so confident of victory as to attack simultaneously. Now, in the case of mounted troops, the side which for the moment feels itself to be inferior will of course take to the rifle. It follows then that a mounted collision will not take place unless the inferior side has no time to dismount, that is to say, unless it is completely surprised. And, even if it has neglected to take any precautions itself, it will probably get warning of the impending charge from the protective detachments necessarily thrown out by the other side. In recent years of peace and war the writer knows of only one case of a mounted collision between bodies larger than a squadron which had any semblance of reality. This was on manœuvres in Berkshire in 1907, when two cavalry brigades met. On this occasion, for reasons into which it is not necessary to enter but which would not arise in war, both sides had almost entirely neglected to protect themselves. Patrols, on the other hand, coming suddenly round corners or over a rise of ground, have often met unexpectedly, and, just as in the case of dismounted patrols at night in No Man's Land, the ground has then remained in the possession of the side which has most quickly made up its mind to charge with the *arme blanche*. While, therefore, horse soldiers will often meet in war, collisions on a large scale in which both sides remain mounted will be seldom seen; but single troops or smaller patrols will often succeed best by immediately riding down on the enemy, and will thereby establish a moral ascendency which will be of the utmost value in the subsequent operations.

In the training of cavalry in the past too much attention has been paid to the mounted collision and too little to the mounted attack of infantry or dismounted cavalry. It has been thought apparently that the latter form of attack would be comparatively rare, and that the machine-gun and quick-firing rifle, reinforced by trenches and wire, would nearly always compel the attacker to take to the rifle himself. To take this view is to assume that cavalry will never meet an enemy who is hopelessly inferior in numbers or spirit, or who has run short of ammunition; to suppose that an army will on all occasions have sufficient time, energy and material to dig trenches and erect obstacles; and to ignore the moral effect of a cavalry charge on both the mounted attacker and the dismounted defender. The events of the World War have shown clearly the fallacy of such ideas. At Cerizay, in the retreat from Mons, the British 5th Cavalry Brigade charged some dismounted cavalry who were acting as vanguard to a force of all arms. The advance of this force was stopped for several hours and upwards of 300 of the enemy were killed, wounded or captured, the British casualties being about 40. When the Germans retired from Péronne in the spring of 1917, three regiments of the British 5th Cavalry Div. galloped simultaneously through the villages of Villers Faucon, Guyencourt and Saulcourt and in a few moments had captured them at a negligible cost of life, the hostile rear-guard fleeing on the first appearance of the cavalry. Reference has already been made to the action of El Mughar in Palestine in 1917, in which 1,000 prisoners were taken by the 6th Mounted Brigade at a cost to themselves of under one hundred. In the same theatre of war in 1918 there were numerous successful charges. For instance, two weak squadrons of the 2nd Indian Lancers met a Turkish battalion at Megiddo, killed 46 with the lance and captured 470; near the Jordan two squadrons of the 29th Indian Lancers secured 800 prisoners, with about 30 machine-guns, in one charge; north of Damascus the 3rd Australian Light Horse Brigade struck a retiring column in flank after galloping six miles, and captured a divisional commander and 1,500 men. In these campaigns, which resulted in the capture of Jerusalem and in the expulsion of the Turks from Syria, the

successes of the cavalry were in fact most of them gained by mounted attacks against a dismounted enemy. Dismounted attacks usually either failed or took so long to organize and carry through that the mobility of the force was to a very large extent nullified. The advantage of a mounted attack is so great from the point of view of a quick decision that it would be justified even if it were more expensive in life than a dismounted attack. But such is not the case. The fact is that for attack cavalry are useless, either mounted or dismounted, unless the enemy is very much inferior or demoralized, and that wherever a dismounted attack will succeed, a mounted attack will also get home much more quickly and at smaller cost. The only exception to this is in the case of ground which is impassable for horses but passable for men on foot. The speed of the mounted charge more than compensates for the size of the target which it presents; but its comparatively low vulnerability, given ground in any way suitable, is due not so much to this fact as to considerations of *moral*. By the exhilaration of the gallop, and the instinctive feeling of superiority of the mounted man over the man on his feet, the attacker is steeled in his determination to come to close quarters. The defender, on the other hand, already conscious of an inferiority in numbers or *moral*, or both, is impressed by the novel sight of several waves of horsemen galloping towards him well opened out, and offering no very satisfactory target. He exaggerates the pace at which they are approaching him and opens fire too soon. At the very moment when they are coming close enough to be really vulnerable, perturbed by the small amount of impression which he has hitherto made on them, he becomes flustered, fails to take deliberate aim, and even forgets to alter his sights. Thus it happens that a mounted charge often achieves the apparently impossible, by which means the most decisive successes in war have always been won.

Shock action therefore is by no means a thing of the past, and mounted troops must carry some arm which they can use while still on their horses. The only sound exception to this rule is in the case of non-regular troops, for the training of whom in mounted action there has been insufficient time. In other words, mounted infantry or mounted rifles should be looked upon as imperfectly developed cavalry, to be evolved into the fully trained article as soon as time allows of it. Now, in the hands of an expert, the most efficient arm for mounted use is undoubtedly the pistol; but in the hands of an insufficiently trained man it is nearly as dangerous to friend as to foe; and the time necessary to produce an expert, or even a safe, shot with a pistol from the back of a horse is such as to be prohibitive, even for regular troops. There remains the shock weapon or *arme blanche*, of which the three possible forms are the sword, the lance, and the short lance or hogspear. The sword is the least efficient against a dismounted enemy, but its use is more easily taught than that of the lance. The lance, both materially and morally, has more effect than the other two, but is very conspicuous and heavier. The hogspear is nearly as effective against a dismounted enemy as the ordinary lance, is easily carried, and its use soon learnt. Certain difficulties exist, however, in connexion with withdrawing it after the thrust. If these could be got over it would be the best weapon of the three.

The principles of shock action are as follows: (1) In all cases the maximum amount of fire support should be given by artillery and automatic weapons. This fire, which should take the form of a sudden burst of extreme intensity, must be continued up to the last possible moment before the collision, and should therefore usually be delivered from a direction different to that of the charge. (2) Some automatic weapons must follow close behind the charge, to pursue by fire and consolidate the ground gained. (3) Since disorganization is quite inevitable as the result of a charge, a reserve must be kept in hand. (4) In the attack of a mounted enemy, weight is the chief consideration. The charge should therefore be delivered without a moment's hesitation, at full speed, in serried ranks, and, if it can be done without delay, down hill. (5) In the attack of a dismounted enemy, moral effect and avoidance of formations vulnerable to fire must be aimed at. Now the sight of a number of successive lines approaching him impresses the dismounted man more than speed or mere numbers on a broad front. The charge should therefore be delivered in depth, well opened out, and not necessarily at a very great pace. (6) Mounted men are particularly vulnerable to enfilade or oblique fire. Consequently, while depth is the more important consideration, the whole of the enemy's front should be attacked, or, if that is not possible, the heads of the defenders on the part not attacked must be kept down by supporting fire from artillery and machine-guns.

Though a mounted is distinctly preferable to a dismounted attack, it will often happen that the approach to the enemy lies over ground which is impracticable to horses, or that he is sheltering behind an impassable obstacle. Recourse must then be had to the rifle. The typical cavalry dismounted attack consists in utilizing the mobility of the horse to gain a position on the enemy's flank whence he can be devastated by fire. Surprise plays a very important part in such an operation. The cavalry man, moving rapidly, can more easily achieve surprise than the foot soldier; moreover, he can, if his attack fails, break off and try elsewhere, an advantage which is denied to the infantry man, with his more limited range of action. The necessity of keeping the enemy engaged frontally while at the same time turning his flank usually entails a wide extension of the force; the maximum number of rifles is put in the firing line from the outset, and small reserves only are retained. The advance is made mounted up to the last possible moment, and the led horses are kept well forward with a view to a further outflanking movement or a pursuit. The immediate objective of the operation is a fire position. For a purpose such as blocking the retreat of an enemy by bringing fire to bear on a defile these tactics are eminently suitable; but it is doubtful whether they will often be successful in other situations. In modern warfare flanks are hard to find and are seldom left unprotected; the operation therefore usually becomes a frontal attack. Indirect artillery fire and aeroplane observation have greatly increased the vulnerability of led horses, and in practice it usually takes cold steel, or the threat of it, to compel the retreat or surrender of the enemy. For the attackers to succeed mounted, considerable superiority is necessary; for a dismounted attack still greater ascendency is required.

In the World War cavalry were often unable to turn the enemy's flank and found themselves committed to a frontal attack dismounted. It was clear that such a situation demanded the assumption for the moment of infantry tactics. Led horses had to be left some way behind; dispositions had to be made in depth with adequate supports and reserves; artillery and machine-gun bombardments had to be arranged for and the attack driven home with the object, not of gaining a fire position only, but of assaulting the enemy. In the future tanks will, when they are available, free the cavalry from carrying out this kind of operation, for which the latter are not well suited by reason of their small fighting strength when dismounted. Still, tanks may not always be present or able to act, and cavalry must know how to attack dismounted in depth.

This kind of attack is of course valueless without the bayonet, which is also required for use defensively in trenches, and for night attacks dismounted.[1] Cavalry may often be called upon in the future for such tasks. It would not seem to be beyond the limits of human ingenuity to devise a short lance, made in two pieces, which could also be fixed to the rifle as a bayonet.

The tactics of cavalry in defence consist in making full use of their mobility to compensate for their weakness in fire strength. Their mobility gives them over infantry the following advantages: (1) They can counter-attack more rapidly, therefore with more chance of effecting surprise; (2) they can move more quickly to reinforce threatened portions of the line; (3) they can retire more easily to a second position. It follows that they can be pushed out to a greater distance, and can hold a longer front than the equivalent number of infantry. The value of

[1] An example of the latter is the successful counter-attack made by the British 12th Lancers, in company with two infantry battalions, at Wytschaete during the first battle of Ypres.

this is most apparent when it is remembered that the vulnerable parts of every force are its flanks. The mobility of cavalry is of course best brought into play in a moving defensive, that is to say, in a rear-guard or flank-guard action. The addition in the middle of the war of 12 automatic rifles to a regiment has greatly increased the fire-power of the arm, but it is to be hoped that in the future some weapon will be evolved which will be less susceptible to inaccuracies and stoppages than the Hotchkiss. It is a waste to use cavalry in a continuous defensive line if other troops are available. The proper dispositions for a cavalry defence are: (1) a chain of localities, with gaps between them, held principally by automatic weapons; (2) reconnaissances far out to the front and flanks, to give ample warning of hostile approach; (3) a large proportion of the force in mobile reserve; (4) careful arrangements for withdrawal to a second position if it should become necessary. But, above all, cavalrymen must not be afraid of a very extended line, relying upon greater mobility and moral superiority to compensate for numerical weakness. The soundness of this doctrine needs no more proof than that furnished by the operations of the British cavalry corps in the first battle of Ypres.

The principles governing the conduct of a reconnoitring detachment will appear simple if it is remembered that the information required is, in each locality, ultimately obtained by one pair of eyes or one pair of ears. The rôle of the rest of the detachment is that of a conveyance, to enable that pair of eyes or ears to arrive at a place whence it can see or hear, and to allow of the news being sent quickly back to the commander. A reconnoitring detachment, then, fights only in order to arrive at its destination or to keep a road open for messages going back. Its strength is regulated by the amount of opposition which is anticipated, and by the number of messengers which will be required. Sometimes it will act by stealth, when its strength will be reduced to a minimum. More often, however, even if it may be possible to get forward without opposition, the difficulty of maintaining a channel of communication will enforce a fighting rôle on a reconnaissance; and, as the result of recent experience, cavalry opinion has veered very decidedly towards strong detachments, not less than a troop, and often as much as a squadron or more. It should here be mentioned that since the commander of the force alone knows how much importance he attaches to obtaining information, he, and not a subordinate, should decide upon the strength of a reconnoitring detachment. In principle, the order "Send out a patrol" should always be followed by a statement of the strength, and this should be insisted upon in all tactical exercises.

The advance of a reconnoitring detachment, like that of all other cavalry bodies of every size, is conducted on the principle of successive objectives, or bounds. This principle, which seemed before the war to appertain exclusively to cavalry, has now been adopted by infantry also; but, on account of the difficulty of maintaining control with fast-moving troops, it is particularly important that it should be thoroughly well understood by cavalry. The idea underlying the principle is that of getting as quickly as possible through specially dangerous areas. A series of objectives is chosen, the occupation of which by the enemy might cause inconvenience; such objectives may be a position covering a defile, a village, a cross-road in enclosed country, a simple eminence giving a good field of view, or some other feature of tactical importance. The distance between them varies according to the size of the force; for instance, a squadron acting as vanguard would be given objectives intermediate to those thought necessary for the brigade following as main body. The main body does not leave one objective till the advanced guard has reached the next; the advanced guard does not move on till the main body is close up to it, but meanwhile prepares the advance to its next objective by sending forward reconnaissances. The movement resembles in fact that of a caterpillar. This principle has very great advantages, though it tends to some extent to retard movement. In addition to providing security for the main body, it gives to the commander of the advanced guard a definite tactical feature for which to fight should he meet the enemy unexpectedly, and so helps him to make up a plan. Also, in the case of two parallel moving bodies, it ensures the heads keeping more or less level with one another.

The commander of a reconnoitring detachment is given his orders in the form of instructions, the framing of which is an important matter. Once despatched, he will have to act wholly on his own initiative; it will not be possible to overtake him to give him supplementary instructions, and he will often be faced with situations entirely unforeseen. He must therefore be given full information respecting the situation at the moment and the intentions of the commander. It is a truism, but one which is often overlooked, that, in order to get definite answers, one must ask definite questions. Instructions such as "to make good" a certain locality, "to work round," or "to clear up the situation" will result in undecided action and vague information. If negative information is required, the places from which or times at which it is to be sent in should be stated. The reconnaissance commander must know how long he is likely to have to stay out and how far he is to go, whether he is or is not to remain in observation when the enemy is met with, and what he is to do in the event of his reaching his farthest objective without meeting the enemy. These two latter points particularly are often omitted.

Not only reconnaissances, but all other cavalry detachments also, go out to greater distances and are left more to their own resources than is the case in the infantry. For them also, therefore, clear and far-seeing orders are essential if they are to perform their task satisfactorily. And besides this there are certain other matters of staff work which require special attention in cavalry formations. For instance, arrangements for even a simple march have to be particularly carefully thought out by reason of the fact that the mounted men can move slightly faster than the light transport of the formation, and very much faster than the heavy transport; motors, too, complicate the problem. The question has always to be decided: Should the transport move with brigades or what is called divisionalized? If the latter, how is it to be assembled before and dispersed after the march? Should it move off first, allowing the mounted men to overtake and pass it, or last, which usually entails a very late arrival at the destination? In infantry formations the fighting troops and the transport move at the same pace, so that comparatively little difficulty arises. Again, horses have to be fed and watered, and should be offsaddled whenever possible; consequently, unless horsemastership considerations are overruled and the formation is kept in a state of instant readiness, cavalry take longer to get on the move than infantry. This drawback can be minimized by enacting that a portion of the force must be prepared to move off instantly and that the rest must be at some particular length of notice. Much can also be done, on occasion, by issuing warning orders, with the object of shortening the length of the orders to move when the time comes to write them. In the future, too, the coöperation of the component parts of the mobile mixed force will require staff work of a very high order.

Lastly, the most brilliant conception of a rôle, the highest degree of tactical skill, the most unerring staff work—none of these will suffice unless the leader has the requisite personality. It is rare indeed that such a personality is found, and the failures of cavalry in the past can be traced more often to the shortcomings of the commander than to any lack of efficiency elsewhere, or to conditions of ground and armament. It is essential, if the formation is to retain its dash, that the commander should be entirely confident of the rôle of cavalry. Now, during periods of stationary warfare, entailing inactivity for the mounted troops, it requires a character of exceptional firmness to retain that confidence to the fullest possible extent. But the principal stumbling-block consists in the facts that a cavalry detachment once sent out can be recalled with difficulty only, and that a mounted attack once launched cannot be recalled at all. Evidently mistakes must often be made, and the strength of the enemy sometimes underestimated. The cavalry leader will fail if he ponders too much on contingencies; he will not succeed

unless to the confidence engendered by knowledge he joins an instinctive appreciation of the situation. It is the possession of this last faculty which has distinguished all great cavalry leaders. It is a plant which is indigenous to a certain soil only, and the components of that soil are knowledge, confidence and dash.

(R. G. H.-V.)

**MOUNT STEPHEN, GEORGE STEPHEN,** 1ST BARON (1829–1921), Canadian financier (*see* 18.942), died at Brocket Hall, Hatfield, Herts, Nov. 29 1921.

**MOVING OR MOTION PICTURES:** *see* CINEMATOGRAPH.

**MUIR, JOHN** (1838–1914), American naturalist and writer, was born at Dunbar, Scotland, April 21 1838. When he was 11 years old his father moved to America and settled as a pioneer farmer in Wisconsin. Here the boy grew up taking an active part in clearing his father's land. When 22 years old he entered the university of Wisconsin, where he supported himself by teaching and working on farms during vacation. After finishing his course he began his wanderings on foot which carried him through many states. Later he crossed to Cuba, and thence to Panama and up the Pacific coast to California. In 1868 he first entered the Yosemite Valley which for many years after formed the base of his continued expeditions. In 1876 he joined the U.S. Coast and Geodetic Survey and three years later made his first visit to Alaska where he discovered the glacier that now bears his name. He was specially interested in glaciation and in the Sierra discovered numerous residual glaciers. In 1881 he took part in the expedition in search of the "Jeanette" and the De Long party in the Arctic region. He was an early advocate of national parks, and it was largely due to his efforts that the Yosemite Park was set aside in 1890. In 1903 he set out on a tour covering the Caucasus, Siberia, Manchuria, Japan, India, Australia and New Zealand; in 1911 he went to S. America to explore the Amazon; and in 1912 he visited Africa. He died at Los Angeles, Cal., Dec. 24 1914.

He published *The Mountains of California* (1894); *Our National Parks* (1901); *Stickeen* (1909, the story of a dog); *My First Summer in the Sierra* (1911); *The Yosemite* (1912) and *The Story of My Boyhood and Youth* (1913). In 1888 he edited *Picturesque California*. The following appeared posthumously: *Unpublished Prose and Letters* (1915); *Travels in Alaska* (1915); *Letters to a Friend* (1915); *A Thousand-Mile Walk to the Gulf* (1916); *The Cruise of the Corwin* (1917) and *Steep Trails* (1918).

See also *The Writings of John Muir* (1916), 6 vols., edited by William Frederic Badè.

**MUIRHEAD, ALEXANDER** (1848–1920), British physicist, was born at Salton, E. Lothian, May 26 1848 and was educated at University College school, London, passing on to University College, whence he subsequently graduated B.Sc. with honours in chemistry in 1868–9, but before doing so he entered his father's works and there invented a method of testing condensers, afterwards widely accepted. In 1870 he became a fellow of the Chemical Society, and in 1872 graduated D.Sc. of London in electrical science. He was an original member of the Physical Society of London (1874) and a member of the Société Française Physique. In 1875 he invented the duplex plan for working Atlantic cables described in 26.518. His siphon recorder (*see* 26.523) is now in general use. Attendance at a lecture on Hertzian waves given by Sir Oliver Lodge at the Royal Institution in 1894 resulted in the Lodge-Muirhead syntonic system (*see* 26.538), which anticipated Marconi. The original idea was Lodge's but Muirhead supplied the practical science required to work it out. He started cable works of his own at Elmer's End, Kent, in 1896, and gave valuable evidence before the commission appointed to inquire into the possibility of laying a Pacific cable. He was elected a fellow of the Royal Society in 1904 and died at Shortlands, Kent, Dec. 13 1920.

**MÜLLER, HERMANN** (1876– ), German Socialist leader, was born May 18 1876 at Mannheim. From 1899 to 1906 he was editor of the Socialist newspaper, the *Görlitzer Volkszeitung*, and from 1906 onwards was a member of the directing board of the German Social Democratic party. From 1916 to 1918 he was a member of the Reichstag. On Aug. 1 1914 he went to Paris on a desperate mission with the object of finding out whether international action by the Socialists of France and Germany could be initiated in order to avert the World War. His mission was unsuccessful, and he had great difficulty in making his way back to Germany through the French lines. His report of his mission did much to determine the attitude of the German Social Democrats in voting in the Reichstag for the first war credit. On June 21 1919 he was appointed Minister of the Reich for Foreign Affairs—under the chancellorship of Gustav Bauer—and in this capacity went to Versailles and with the Colonial Minister, Bell, signed the Peace Treaty for Germany on June 29 1919. After the resignation of the Bauer Ministry, which followed upon the Kapp *coup d'état* (March 1920), Müller was appointed Chancellor of the Reich, an office which he held till the following June, when the result of the general elections for the Reichstag necessitated the formation of a Coalition Ministry with Fehrenbach of the Catholic Centre party as Chancellor. Thereafter Müller continued to play a leading part in the affairs of the Social Democratic party.

**MUN, ADRIEN ALBERT MARIE DE,** COUNT (1841–1914), French politician (*see* 19.1), was an energetic advocate of the Three Years Service law of 1913, and his support of the Barthou Ministry during the passage of this measure was very valuable. He published various pamphlets and volumes of speeches, the last being *La Guerre de 1914*. He died at Bordeaux Oct. 6 1914.

**MUNITIONS OF WAR.**—Under this heading, while it would be impracticable to refer to what was done by all the belligerent countries, the organization of the production of munitions during the World War by the United Kingdom and in the United States, on the one hand, and by the Central Powers on the other, is dealt with. Its history in the United Kingdom is told first.

## I.—UNITED KINGDOM

*The Problem.*—When the British army of six divisions took the field in 1914 it possessed about 900 field guns, less than 200 field howitzers, about 60 heavier weapons of 6-in. and upwards and perhaps about 200 obsolescent types, such as the 4·7-in. and the 85-pdr. howitzer, a reserve of ammunition of less than a million rounds weighing some 20,000 tons, and less than 2,000 machine-guns. By the end of 1918, the army had received 10,000 field guns, 6,000 other light guns, over 3,000 field howitzers and 7,500 heavier guns and howitzers; 217 million rounds of artillery ammunition weighing 5¼ million tons and nearly 225,000 machine-guns.

The revolution in the material means of waging war was one which none of the belligerents entirely foresaw. It is true that the German and, to a less extent, the French army had munition reserves on a vastly greater scale than the British; but Germany counted upon a short war, and as she had not made adequate preparation for a continuous industrial effort, her armies were strictly rationed in 1915 while her resources were being mobilized. France was quick to appreciate the significance of the bombardments of the early battles, and in Oct. 1914 set machinery in motion for organizing her industrial resources under the direction of M. Thomas, who was appointed Under-Secretary for War in charge of munitions. For this task France had available a large number of expert officers who had passed through the arsenals, and these were placed in charge of districts in which they combined inspection with control of supplies.

Great Britain, on the other hand, was for various reasons slower to realize the change that had occurred, and in any case had a much smaller trained personnel and equipment for producing land munitions than the continental Powers. The Royal Ordnance Factories were, of course, at once set to work at fullest pressure and in October very large orders were placed with the armament firms who were given very wide instructions to expand their production. Mr. Ernest Moir was also sent to France to report on the schemes of the French Government. But time was needed to enable the situation to be seen in true perspective, for Great Britain was faced not merely with the task of providing a new and unprecedented scale of equipment, but also with the need of enlarging the expeditionary force into a continental army. On this last point opinion was slowly changing during the winter of 1914, but even in the

spring of 1915 a large section of instructed opinion still urged that Britain's best contribution to the Allied cause was to conserve her economic strength and carry on "business as usual."

In this environment the authorities at the War Office, many of whose most experienced personnel had been sent to the front, and who were overburdened by the colossal problem of keeping the army supplied with its most urgent daily necessities, failed to appreciate fully the change needed in the standard of equipment and the sweeping character of the plans that would have to be made for dealing with it. At the outbreak of war, for example, the standard of machine-guns was 2 per battalion and it was not until the spring of 1915 that this was raised to 8 per battalion. At the end of the war the standard worked out at 48 per battalion. As regards ammunition a small increase in the number of rounds per gun per day on which the programme of field-gun ammunition was based was made before Christmas 1914; by the early summer of 1915 the basis was raised to 25 rounds per gun per day for field guns and in Sept. 1916 to 50 rounds per gun per day. One reason for this moderation was that in the early months of the war the officers in the War Office who framed the munition programme constantly had in mind the limited capacity of the country for producing munitions, and it was not until the middle of 1915 that this consideration was abandoned.

*War Office Policy.*—This point of view led to a conservative attitude in the placing of contracts. With its staff both at headquarters and in the inspection departments seriously depleted, the War Office not unnaturally clung to old and tried sources of supply and limited its orders during 1914 to Government factories and the armament firms. It relied for increased supplies on extensions to the Royal Ordnance Factories and at the works of Messrs. Vickers and Armstrong's (for ammunition and other munitions), Coventry Ordnance Works (chiefly for field guns and howitzers) and the Birmingham Small Arms Company (for machine-guns), leaving it to the armament firms to obtain any further increase from the engineering resources of the country by placing their own sub-contracts. The immediate result was a big demand for labour from these armament firms, and while this was at first forthcoming, the continued absorption into the army soon made the position difficult. At the request of the War Office, therefore, the Labour Department of the Board of Trade carried out a brisk campaign in Jan. 1915 for the recruiting of labour for these firms. This canvass produced only small results. It brought to light, however, the strong objection of the ordinary engineering firm against permitting their most essential men to be passed on to the armament firms and the demand that contracts should be more widely distributed.

This claim was constantly pressed by the Board of Trade; but during the spring of 1915 the War Office adhered to the policy of dealing only with the armament firms, and continually pressed for labour to be supplied to them. In March, however, the War Office permitted an exhibition of samples of munitions to be held at the central offices of the labour exchanges in the main towns of the country, and as a result a few small contracts were placed with individual firms.

*Armaments and Treasury Committees.*—The nation was, however, rapidly realizing the need for more drastic treatment of the problem, and at the end of March Lord Kitchener appointed an "Armaments Output Committee" in the War Office under the chairmanship of Mr. George Booth, a shipowner and banker. A week later the Government appointed a committee under the chairmanship of Mr. Lloyd George—known as the "Treasury Committee"—to take charge of munition policy. The "Armaments Output Committee" at the War Office at once became in effect the executive instrument of the Treasury Committee, and one of its first actions was the securing of an order for the Leicester coöperative group. During the months of April and May the Armaments Committee, on which Sir Percy Girouard (a director of Armstrong's) had now joined Mr. Booth, brought into existence several local committees to produce munitions in some cases by coöperative effort and in others to institute national factories to which the various firms would contribute machinery and labour. At first an effort was made to maintain the predominance of the armament firms in certain areas by giving them within these districts a first call on the available engineering labour. Another plan was for the armament firms to "mother" the new contractors and exercise a general supervision over the work of a district. But after much discussion all restrictions in favour of the armament firms were definitely broken down, and by the time the Ministry of Munitions was formed it had become evident that the list of direct contractors must be enormously increased. Following the lead of Woolwich the armament firms thereupon threw open their doors to visiting parties of engineers to learn and study the method of shell, fuze and other armament production.

But while orders could be and indeed had been placed on a large scale, deliveries were not forthcoming. The Armaments Committee endeavoured to deal with some of the difficulties by setting up a machine-tool department in the charge of Sir Alfred Herbert, who at once issued instructions to machine-tool makers to give priority to orders in hand for the British Government or for armament contractors. A raw materials section, which was placed in May under the charge of Mr. Leonard Llewellyn, also began an inquiry into the situation as regards copper, brass, aluminium, lead, antimony and spelter.

*Labour.*—A still greater difficulty was labour. For several months the Board of Trade had been making great efforts to deal with the labour situation, and in particular to check the recruiting of skilled engineers, both from armament and other engineering works. Lord Kitchener's view on this matter was that any man who wished to enlist should be permitted to do so, and it was not until March 1915 that he accepted the principle that it might be of greater national advantage to retain a skilled munition worker at his occupation in the workshop than to allow him to join the army. A beginning was made in April 1915 by scheduling certain occupations in respect of which the recruiting officers were to discourage enlistment, and by issuing badges to men in armament firms to save them from the pressure of public opinion, which at this time was being exerted very forcibly on able-bodied men to join the army.

But the labour shortage in the spring of 1915 was approached not only from the point of view of numbers of skilled men in employment. Attempts were also made to increase production by diminishing lost time, suspending such trade-union rules as restricted output, and admitting semi-skilled, unskilled or female labour to do part of the work hitherto done by skilled men. Up to Christmas 1914 negotiations on these points took place between the shipbuilding and engineering employers and employed, but without result. In Jan. and Feb. 1915 a sudden rise in prices and acute competition for labour between the various Government contractors produced considerable migration of labour and a general state of unrest, which found expression in a series of strikes. On March 15 the engineering workpeople agreed with the employers that, to a limited extent and as experience proved necessary, semi-skilled or female labour might be substituted for skilled labour subject to certain conditions, of which the most important was that the substituted workpeople should be paid the district rate of the men replaced. These relaxations were to be withdrawn at the end of the war.

This, however, hardly went far enough, and, as the result of a series of conferences held between March 17 and March 27, the trade-union leaders signed the Treasury Agreement, under which they undertook to recommend their constituents to suspend restrictive practices for the period of the war in return for an undertaking that the Government would see that the profit resulting from these suspensions did not go to private employers. This agreement coincided with the passing of a Defence of the Realm Act which authorized the Government to "take over" firms engaged on munition work. It was at first intended that this should involve the actual control of the four big armament firms in the same way that the Government had "taken over" the railways. But after negotiations with these firms the idea of handing over their management to an executive committee

was abandoned, and the limitation of profits retained as the only substantial element in "taking over." On the other hand, it was increasingly evident that the same rule would have to apply to a far wider field than the four big armament firms. Hence the agreement was not at this time carried into effect, since the trade-union leaders found it difficult to carry out their part of the bargain in practice, while the negotiations with the firms dragged on until the Ministry of Munitions came into existence. The labour situation was complicated during this period by the efforts of various employers to entice away the skilled labour of their competitors, and considerable loss of output was suffered by the migration of labour.

*Foreign Orders.*—At a very early stage the inability of contractors to guarantee prompt delivery led to the placing of orders in America and Canada. These orders, though not very large in amount compared with subsequent purchases, had one important result in the conclusion of a commercial agency agreement between the British Government and Messrs. J. P. Morgan & Co. of New York, who were made solely responsible for the purchase of British munitions in the United States. Orders had been placed by the War Office for 4·7-in. shell and for nitrocellulose powder as early as Oct. 1914, followed in November by orders for rifles, metals and explosives. By the end of the year not only Great Britain but the Allies and the armament firms in all Allied countries were negotiating for munitions, materials or machinery, with the result that considerable confusion and competition existed. Hence, in Jan. 1915, an agreement was arrived at under which Messrs. J. P. Morgan & Co. were made sole purchasing agents for the British Government on the basis of a commission of 1% on all purchases made. At this time the War Office anticipated that the value of these contracts would not exceed 10 millions sterling, but by the middle of the year it was, in fact, approaching 100 millions and by the end of the year was over 200 millions. The large commission payable on these orders subsequently gave rise to some criticism; but Messrs. Morgan had in effect to create a munitions department to deal with this immense volume of business without the powers which the War Office and subsequently the Ministry of Munitions exercised in Great Britain. This organization was placed in charge of Mr. E. R. Stettinius of the Diamond Match Company, and the efficiency of its service and the enterprise shown by the commercial agents in protecting the interests of the British and subsequently of the Allied Governments proved of immense service to the Allied cause. The arrangement continued until shortly after America came into the war, when other machinery was needed for obtaining supplies owing to the institution of far-reaching control by the American Government.

*Rifles.*—During these early months public attention was mainly devoted to the question of ammunition. But in fact an even more urgent problem was that of rifles, the manufacture of which requires not only very specialized machinery, but also demands labour of special experience which could only be slowly increased. On the other hand, the number of rifles required for training and equipping a rapidly growing army as well as for replacing wastage in the field was far in excess of the stock in the country. For training purposes old-pattern rifles were repaired and resighted and a considerable number of rifles borrowed from Japan. But the date at which the new armies took the field was largely governed during the first twelve months of the war by the slow but steady increase in the output of service rifles, most of which were supplied by the Government arsenal at Enfield. Early in 1915 the War Office became seriously disturbed at the slow rate of increase in production, and finally orders for a million rifles of a slightly modified Enfield pattern were placed early in April 1915 in America with the Remington Co. which had already been given a large order for rifles of Russian pattern. This order was subsequently increased and additional orders placed, but though delivery was originally promised for the autumn of 1915, the rifles were not in fact available before the summer of 1916 and on arrival were found to need adjustment before they could be issued for service. As the cumulative output of Enfield and of the private firms in Great Britain had by that time overtaken requirements and the wastage in trench warfare had proved less than was feared, none of these American rifles were ever actually sent into the field with the British army. The effect of these orders was, however, that when America came into the war she had available two or three of the largest and most modern rifle plants in the world, which had just come into full production.

*Situation in May 1915.*—By May 1915 it was still uncertain how large a force Great Britain would endeavour to put into the field, and the War Office was still far from realizing the great increase that must be made in the standard of equipment. Substantial orders had been placed at home and abroad; and at home, as a result mainly of civilian pressure, a beginning was being made to place these contracts outside the range of the armament firms. It was, however, fast becoming clear that no contractor would, without assistance, be able to steer through the rising confusion of economic disturbance, and that the Government would have to assist contractors with both plant and material. But the War Office had neither the staff nor the experience to institute effective statistical or technical control over so large a commercial business. A treaty had been made with the labour leaders to abolish restrictive practices and to permit the employment of female and unskilled labour, but the arrangement was not being carried out in the shops. Hence the enormous orders which had been given to the armament firms were not being fulfilled, and subsequent events proved that if the goods had been delivered the inspection, storage, and transit organizations would have been unable to cope with them.

*The Ministry of Munitions.*—The Ministry of Munitions was an inevitable consequence of the failure of contractors and subcontractors to cope with this economic situation, and of the fact that the War Office had not the technical resources, even if it had the will, to create the organization needed for handling so complex and so rapidly changing a problem. It was stated on May 14 by the military correspondent of *The Times* (approved by G.H.Q., France) that "we had not sufficient high explosive to level the enemy's parapets to the ground after the French practice." It may be noted in passing that, although this comment refers only to H.E., there were two aspects to the problem, namely (1) inadequacy of ammunition as a whole, and (2) the proportion of shrapnel and H.E. respectively to be supplied for field artillery. On the latter question British tradition had always favoured shrapnel, whereas French practice was to use practically all H.E., with their famous 75-mm. field gun. Experience eventually proved that 18-pdr. H.E. shell, which contained only 13 oz. of H.E., was of little use for destroying deep entrenchments, and it was ultimately limited to use against personnel, against surface works and for wire-cutting.

On the British front the last of these tasks continued mainly to be done by means of shrapnel. Hence, in spite of the fact that, when the initial difficulties had been overcome, the H.E. 18-pdr. shell was easier to manufacture in quantity than shrapnel, the British army in France throughout the war fired only 40 million rounds of H.E. compared with 60 million rounds of shrapnel (of which less than 3 million were fired up to the end of 1915). The event in fact proved that the more fundamental deficiency was in heavy artillery firing H.E. shell of large calibre —the standard types of which were ultimately the 60-pdr. shell containing rather more than 6 lb. H.E., the 6-in. howitzer shell weighing 100 lb. and containing 12½ lb. of H.E., the 8-in. howitzer shell weighing 200 lb. and containing 20 lb. H.E., the 9·2-in. howitzer shell weighing 290 lb. and containing 34 to 52 lb. H.E., and the 12-in. howitzer shell weighing 750 lb. and containing 66 to 105 lb. H.E. In this respect G.H.Q., equally with the authorities at home, were open to the criticism of being slow to see future developments, since at this time they had not put forward any large demand for heavy artillery.

The *Times* article, backed by the authority of the army in the field, confirmed the growing fear that the British troops were inadequately supplied with ammunition compared with the enemy or even with the Allies. The political crisis which ensued brought the Ministry of Munitions into being, with

Mr. Lloyd George at its head, and the members and staff of the Armaments Output Committee and of the Treasury Committee as the nucleus of its personnel.

The first year of the Ministry of Munitions was the creative period not only as regards the internal structure of the Ministry itself, but also in regard to its main duties. It was a period in which army demands were defined, manufacturing programmes laid down, methods of dealing with labour formulated and put into effect, large numbers of specialized factories designed for mass production constructed, and devices evolved for exercising control over the industrial life of the country.

The Ministry of Munitions Act, which received the Royal assent on June 9 1915, did little more than create the post of Minister of Munitions. The definition of his functions was left to be fixed by Orders in Council. The Act was therefore followed a week later by an order transferring to the Minister of Munitions the main functions of the Master-General of the Ordnance in relation to contracts and the supply of munitions (including explosives) and the inspection of munitions. The Minister of Munitions was given concurrent power with the War Office under the Defence of the Realm Act which gave authority to take over and regulate the work of any factory. The Minister was also given a general duty to "examine into and organize the sources of supply and the labour available for the supply of any kind of munitions of war, the supply of which is in whole or in part undertaken by him, and by that means, as far as possible, to ensure such supply of munitions for the present war as may be required by the Army Council or the Admiralty or may otherwise be found necessary."

In the first instance the War Office retained the control of the ordnance factory at Woolwich, the small-arms factory at Enfield, and the Waltham powder factory, and also the right to lay down the standards of inspection to be observed by the inspectors in the factories. Provision was made, however, for the transfer of these or any other functions in the future as might be agreed upon between the Minister of Munitions and the Secretary of State for War or the head of any other interested department, such as the Admiralty.

The ordnance factory at this time and for many months to come was doing the lion's share in supplying the army with munitions, not only because of the volume of its output but even more because its large supply of skilled labour, its staff of technical officers, and the fact that it had drawings and specifications available of all stores in army service, made it the only means of supplying the sudden and often small demands which the inadequate and miscellaneous character of the equipment in the field made inevitable. The War Office was therefore unwilling to hand over so vital an institution until the new organization had got on its feet. The transfer was, however, made in Sept. 1915.

*Internal Organization.*—From the outset the work of the Ministry fell into two main sections: that concerned with the supply of munitions and all that this involved in technical assistance to contractors, supervision of inspection, stores, transport, control of materials and regulation of non-munition work; and, on the other hand, the regulation and control of munition labour. These two functions divided the Ministry into two divisions which were housed in separate buildings and developed along divergent lines of organization. The labour section of the Ministry, staffed largely by personnel drawn from the Labour Exchanges Branch of the Board of Trade, developed its organization on civil-service principles, the heads of departments reporting to the Minister through the general secretary of the Ministry, Sir Hubert Llewellyn Smith. The business men, on the other hand, who were called in as heads of the supply departments, had a profound distrust of orthodox Government methods and demanded the right of direct access to the Minister. A brief controversy on this point between the general secretary and the director-general of munition supply (Sir Percy Girouard) ended in the latter's victory. This was perhaps justified by the imperative necessity for prompt action; and as Mr. Lloyd George encouraged the heads of departments to act upon their own responsibility on the basis of general instructions, it enabled a large number of activities to be pressed forward at the same time. It had the effect, however, of making the general secretary practically head of the labour sections only of the Ministry; and moreover, as the right of access was secured not only by Sir Percy Girouard (who was succeeded in August by Sir Frederick Black), but also by the deputy directors—Mr. Glynn West (in charge of ammunition), Mr. Booth (establishment, foreign orders, etc.), Mr. Eric Geddes (small arms), Mr. C. E. Ellis (guns)—and by the heads of the departments of explosives (Lord Moulton) and trench warfare (Gen. Louis Jackson, and Mr. Alexander Roger), and as the number claiming this privilege continued to increase, it gave rise to difficulty in coördinating the work of the various sections. Within the first few weeks, these various heads of departments went to the corresponding sections of the War Office, discussed requirements and gave instructions to the contracts department or placed their own contracts, without reference to the programme of the department as a whole. This difficulty was overcome by setting up a "Requirements and Statistics" department, whose primary duty was to be the sole official channel of communication between the Ministry of Munitions and the War Office on all questions relating to supply. Informal discussion was encouraged, but the various departments were authorized to act only on the formal demand from this new department. Since this department had passing through its hands the programme as a whole, it was also given the duty of compiling the statistics of the Ministry and receiving weekly progress reports from the supply departments.

The diversity of experience in organization among the business men also led to confusion in the mechanical arrangements for distribution and registration of papers, and it was some months before the newcomers grasped the essential difference between acting as head of a section of a large public service which is a part of a still greater whole and acting as head of a private business. These defects, which arose from the very qualities which enabled the Ministry successfully to set rapidly in motion and ultimately to control the immense industrial reserves of the country, finally induced Mr. Lloyd George in March 1916 to change his headquarters from the labour department to the main supply department. In March 1916, Mr. E. B. Phipps was transferred from the Board of Education as second general secretary to take charge of the mechanical organization of the supply departments.

*Munitions of War Act.*—The first task of Mr. Lloyd George was to make the country realise that the munition effort must be second only in importance to the work of the army in the field, and must override all such ideas, for instance, as of the importance on economic grounds of maintaining the export trade. Hence during June he undertook a campaign of speeches in the chief industrial centres to prepare the minds of both employers and workpeople for the very great restrictions imposed by the Munitions of War Act.

The chief provisions of this Act (July 2 1915), which brought to a head the developments in the labour situation seen during the first year of the war, may be summarized as follows:—arbitration in disputes as to wages, hours and conditions of service made compulsory; strikes and lockouts prohibited; Minister authorized to declare factories "Controlled Establishments"; profits of these establishments limited by means of a tax known as the "Munitions Levy"; no wage changes to be made in controlled establishments without consent of Ministry; migration of labour prevented by provision that a controlled establishment must not engage a man unless he held a "leaving certificate" from previous employer; Minister authorized to demand statistical returns; Minister given authority to issue badges which protected men from pressure to join the army and to suppress illicit badges; Minister authorized to create corps of war munition volunteers available for transfer at his discretion; Minister authorized to demand removal of labour from non-munition work. The administration of the labour sections of the Act was placed in the hands of "Munitions Tribunals" set up in all industrial centres. The Act had con-

siderable success in stabilizing labour conditions, and brought to an end the period of unrest.

Almost immediately the Act was passed a strike occurred in the South Wales mines, and it required a personal visit of the Minister to persuade the men to return. But this was the last serious outbreak for a very considerable period.

In regard to female labour and the abandonment of union rules, the objections of the ordinary trade unionist to permitting unskilled labour to do work previously regarded as skilled had been steadily weakening as the shortage of labour became more acute, and as experience of making shells and fuzes on repetition methods spread through the country it became more obvious that the work was unskilled. Finally the disinclination to surrender pre-war practices had largely arisen from the fact that it was impossible to prevent the changes spreading to private work, and in any case it was extremely difficult to distinguish between Government and private work; but as the year proceeded private work fell more and more into the background. Prejudice on the part both of employers and workpeople against the employment of women in engineering work had still to be overcome. The men's opposition to the women was considerably appeased by the decision that women doing skilled or semi-skilled work should be paid the same rate as the men displaced, while the fixing of a minimum wage for unskilled female labour of £1 a week tended to raise the level of women's wages in general and minimize the possibility of men's wages being prejudiced. A department was started to encourage welfare work in the factories, and in many congested districts housing and hostel schemes were initiated. From the passing of the Act the employment of women on munition work increased continuously until the end of the war. In the succeeding six months, the "badging" system of the Ministry (*see* LABOUR SUPPLY AND REGULATION) caused a decided check to recruiting from the engineering factories. Indeed, at a later stage it appeared that badges had been given rather too freely, and many badged men were ultimately released for service. The plan of mobilizing a corps of war munition volunteers met with only a qualified success at this period, and a great difficulty was experienced in obtaining the release of men from the army. This problem was somewhat simplified after the introduction of compulsory military service.

The "Munitions Levy" was ultimately succeeded by the general Excess Profits Duty, leviable on all firms in the country, and the assessment passed from the Ministry into the hands of the Board of Inland Revenue. This Act, which created the powers exercised by the labour section of the Ministry of Munitions, involved a very extensive interference by Government with the liberty of the individual worker, and was the more remarkable since at this date the army was still dependent upon voluntary enlistment. Its passage was only made possible by the clauses limiting private profit on munition work.

*The Production Programme.*—Early steps were taken to ascertain the general requirements of the War Office. But the Minister, in view of the circumstances of his appointment, considered himself in no way bound by these demands, and held that he was free to place such orders as would ensure an enormous increase in the munition-making capacity of the country and also to look very far ahead in placing orders abroad.

*Guns.*—The most notable action of Mr. Lloyd George in this respect was in the matter of heavy artillery. In June 1915 a conference on munitions was held at Boulogne, at which French experts strongly urged the necessity of increasing enormously the proportion of heavy artillery per division. Field artillery had practically no effect on deep trenches, and as the whole front had become a vast entrenchment it was necessary to contemplate having in the field as many heavy guns as field guns. Following upon this conference, Sir John French put forward a demand to the War Office to provide for each division and army corps a definite establishment of heavy guns and howitzers 6 in. and upwards. This standard was worked out on the basis of 50 divisions and put forward as a definite demand. In view, however, of responsibilities in other theatres of war and of pressure from the French Government, the War Office was already laying its plans on the basis of 70 divisions. The gun programme, therefore, before being passed to the Ministry was proportionately increased and an allowance added as reserve. On receipt of this demand the Minister early in July allocated these orders among the armament firms and authorized the necessary extensions to plant and the purchase of the large quantity of machine tools required from English and American manufacturers. It was obvious, however, that the scale of the plant to be developed would determine the date at which these enormous orders could be fulfilled. Mr. Lloyd George had at this time urged the necessity of increasing the British military effort to 100 divisions. Partly with this object in view and partly to broaden the basis of the munition output of Great Britain, which was still far behind that of Germany, he increased the programme on his own responsibility in Aug. 1915 to a 100-division standard, and ordered all the consequential demands for shell, fuzes, explosives, propellants, steel, etc., to be calculated on this basis. This action was much criticized, both on the ground of expense and the alleged impossibility of training personnel to man so vast an armament. But Mr. Lloyd George was supported by the Cabinet, though arrangements were in train in the spring of 1916 for handing over the surplus to the Allies, and particularly to Russia if and when it matured.

Within a few days, however, of the opening of the battle of the Somme in July 1916, G.H.Q. revised their ideas and put forward an entirely new basis of equipment. The establishment of 6-in. howitzers, which had seemed large in July 1915, was trebled; the demand for 8-in. and 9·2-in. howitzers was doubled, while a new item was added in the shape of heavy long-range guns. When the programme was examined it was found that the surplus orders of the Ministry covered these increased demands for all heavy howitzers except the 6-in. and that only comparatively small additions to the existing gunmaking capacity would be required to enable the Ministry to cope with the whole of the new programme. So complete a vindication of Mr. Lloyd George's courageous action, with its far-reaching consequences in the subsequent campaigns, marks it as one of his great contributions to the Allied cause. Indeed, his contention that gunmaking capacity would be one of the vital factors in the campaign was repeatedly confirmed by subsequent events which involved new calls upon British gunmaking capacity. In the first place French experience at Verdun, and subsequently British experience on the Somme, soon showed not only that wastage by destruction would be far larger than had been anticipated, but also that expenditure of ammunition was on so huge a scale that the number of guns worn out and needing relining would be very large indeed. Secondly, it was decided before Christmas to arm all merchant ships with two guns capable of coping with submarines. Thirdly, an urgent and increasing demand arose for anti-aircraft guns, not only on the front but also for the defence of London and many other strategic points in Great Britain. Finally, the development of the use of tanks on a large scale called for the production of an enormous number of guns of small calibre.

Hence it was not until the middle of 1918 that the output of guns of all kinds became sufficient for these combined requirements, and after the output and importation from America of large-calibre shells had enabled heavy stocks to be accumulated, it became necessary to divert some of the projectile factories from shell-making to the repair of guns.

*Ammunition.*—The highly technical processes involved in gun manufacture remained for the most part in the hands of a comparatively few firms. The ammunition programme, on the other hand, with its immense drain on materials and plant, until the end of the war absorbed more than half of the energies of the Ministry and of the munition factories, and was the main cause for the control which was ultimately imposed upon the industry of the country. The shell itself, which at first figured so largely in public discussion, is, as its name implies, merely a container of H.E. or of bullets, and the problem of finding sufficient explosive, propellant, fuzes, primers, cartridge cases and the score or so of other components which go to make up a round of ammunition, proved much more difficult than the manufacture of the shell. The balancing of output, including the appropriate provision of the various metals or chemical substances, was not accomplished without much experience; and as from time to time particular items were ahead or in arrears, the Ministry had to provide for the accommodation of large stocks at all stages of production. The programme thus involved the building-up of a colossal stores organization, the burden upon which was greatly increased by the irregularity in the rate of consumption on the front. Moreover, as the Ministry found it necessary to make itself directly responsible for supplying materials to contractors it became not merely a purchasing department but one of the greatest selling organizations in the world.

The ammunition programme was calculated from the enlarged artillery programme on the basis of the expenditure per gun per day asked for by G.H.Q. But as it was impossible accurately to foresee to what extent new firms or new shell factories would produce the output expected from them, there was added to the net shell demand a margin of 50% in the case of light shell (up to 4·5 in.), which had been ordered largely from inexperienced firms, and 33% in the case of heavier natures, which at first were confined to more experienced firms or new factories built for the purpose. Orders for the former were placed to a large extent through the local committees called into existence by the War Office Armaments Committee or by the Ministry during the June publicity campaign. In some cases the

orders went to special factories, in others to coöperative groups, the whole organization being bound together by a local office of the Ministry under a special directorate (in charge of Mr. James Stevenson) at headquarters. The supply of heavier shell was met by orders with armament and other selected firms, but when the programme was increased in Aug. 1915, it was decided that "national projectile factories" should be built for the Ministry and managed by the various experienced firms on a commission basis. These factories, laid out for a special purpose, ultimately proved highly efficient in mass production and enabled an enormous saving to be made in cost. Additional orders for both light and heavy shell were also placed in America and Canada.

Experience proved, however, that light shell could be turned out much more readily than fuzes and other components, and they began to come forward rapidly and before the filling factories were ready to deal with them. The American share of the programme had also been ordered for early delivery. Hence, by the summer of 1916, an enormous stock of light shell had accumulated, partly as a deliberate policy and partly from fortuitous causes. At various dates, therefore, in 1916 light-shell orders in America were allowed to terminate and output at home cut down, and the machinery partly turned on to heavy shell.

The new artillery programme of July 1916, however, based upon experience on the Somme, not only absorbed the surplus Ministry orders for heavy artillery, but also raised the daily ammunition ration for heavy guns. The Minister was still uncertain what output would be attained in the national projectile factories, which were only then coming into production, and therefore almost his last act at the Ministry was to place large orders in America and Canada, in the two natures in which the biggest increase was asked for, viz. 8-in. and 9·2-in. shell.

Shells could be made in any engineering shop; but explosives could only be handled in factories built for the purpose. Hence, as soon as the ammunition programme was settled the ammunition department set to work to plan and to build a dozen large filling factories, which were rapidly completed and began to handle shell in Feb. and March of 1916. The task of these factories was, however, not merely the technical one of filling shell, making cartridges or filling fuzes, but also that of assembling all the necessary components in proper proportion and of handing to the army in complete condition as rapidly as the Ordnance Department could accept delivery. At Christmas 1915 the organization of these filling factories was divided from ammunition manufacture and handed to a new department. During the spring their work was delayed not only by inexperience, but also by the inability of the technicians to find a satisfactory fuze for detonating amatol filled H.E. shell which would avoid the Scylla of over-sensitiveness, with the resulting casualties to the troops through prematures or gunbursts, and the Charybdis of excessive safety, resulting in "blinds" and ineffectiveness against the enemy. Work at the highest possible pressure at Woolwich at last solved the problem, and solved it so satisfactorily that, a year later, British artillery was probably more immune from prematures, etc., than any other. But the constant change of processes during these critical months held back the factories from getting on with bulk production, and it was not until the middle of May that the Ministry began to hand over large supplies to the army. The date of the Somme offensive was largely determined by these considerations.

*Explosives and Propellants.*—Special steps to develop the production of explosives were taken in 1914—the problem of increasing the output of tri-nitro-toluol (T.N.T.) and other explosives being remitted to a committee under the presidency of Lord Moulton. Hence, when the Ministry was formed, plans were not only in hand but had already achieved considerable success. Pressure had been put upon gas undertakings throughout the United Kingdom to extract the utmost amount of the by-products of coal distillation at the expense of the illuminating-power of their gas, in order to increase the supply of toluol and of benzol, which Great Britain had begun to supply to France. When the Ministry was formed Lord Moulton's department was transferred, and charged in addition with the supply of propellants. At that time this consisted almost entirely of cordite, of which the supply was fairly ample owing to the large capacity which had been developed for naval purposes.

When, however, the new ammunition programme was decided upon, it was evident that the supply both of H.E. and of propellants would also have to be enormously increased. So far as explosives were concerned it was evident that the world's available supplies were insufficient to enable the programme to be carried through by means of either pure T.N.T. or picric acid. It was known that in theory a mixture of T.N.T. and ammonium nitrate could be made to produce as violent a detonation as pure T.N.T., and that the French army was in fact using a mixture of picric acid and ammonium nitrate. In order not to compete for the supplies of picric acid, it was decided to rely upon a mixture of T.N.T. and ammonium nitrate (amatol), and the design department was set to find a means of satisfactory detonation.

The result of their efforts was that during the war, out of about 625,000 tons of explosive supplied, only 210,000 tons (of which 35,000 tons were imported) was T.N.T., less than 80,000 tons picric acid, and the rest ammonium nitrate.

In the case of propellants the stocks and manufacturing capacity for cordite in autumn 1915 were fairly large, and as early steps were taken to increase output its supply never delayed the ammunition programme throughout the war. Its production was, however, limited by the supplies of acetone, and even when an ether-alcohol solvent was used as an alternative to acetone, it was not possible to meet the enlarged programme by cordite alone. The army had accepted as propellant for certain guns a nitro-cellulose powder, which was the standard charge on the Continent before the Ministry came into existence, and since it was not manufactured in England orders had already been placed in America. One of the earliest acts of the Ministry was to place, with Messrs. Dupont of America, enormous additional orders sufficient to justify the manufacturers in making large additions to their plant.

From that date onwards the question between cordite and nitro-cellulose continually exercised the minds of the Ministry. The argument for importing finished propellant was the great saving in tonnage involved, since it is necessary to assemble several tons of material for each ton of propellant and nearly all of the material had to be imported—mostly from very great distances. This advantage had, however, to be balanced against the consideration that, so long as Great Britain remained dependent on a neutral country for a substantial proportion of its propellants, the supplies were out of British control so far as the manufacture was concerned, were liable to serious losses from submarine activity, and in danger of interruption should the United States Government for any reason desire to prohibit the export of munitions. Towards the end of 1916 the last of these considerations assumed considerable importance; and as at that time the use of nitro-cellulose had been adopted for a considerable number of types of artillery, it was decided to commence the manufacture of nitro-cellulose powder in Great Britain. A large factory was projected, but was abandoned when America came into the war.

The novelty of the supply both of explosives and propellants led to the building of large national factories to supplement the limited capacity of the factories in private hands. Indeed, the largest industrial venture of the war was the propellant factory at Gretna, the scale of which is illustrated by the fact that its acid-producing capacity exceeded that of the whole country before the war. As it was considered expedient to build not only out of range of enemy aircraft but also away from industrial centres, it involved building a town to house the workpeople. The factory, which cost £8,000,000 to build, made nearly one-fourth of the cordite required by the army during the war, at a considerable saving of cost.

The relative importance of home sources and of imports of explosives and propellants is shown in Table I, which gives the percentages of the total output during the war:—

TABLE I.

| | Trade | National Factories | Imports |
|---|---|---|---|
| Picric Acid | 92 % | 6½ % | 1½ % |
| T.N.T. | 21 | 63 | 16 |
| Ammonium Nitrate | 65 | 30 | 5 |
| All Explosives | 53 | 39 | 8 |
| Cordite | 47 | 38 | 15 |
| Nitro-cellulose | — | 2 | 98 |
| All Propellants | 26 | 22 | 52 |

The explosive output involved a greatly increased supply of nitrate from abroad. At first this was readily forthcoming, but at an early date Allied competition led to difficulties in Chile, and later, when lack of tonnage made it difficult to spare ships for so long a voyage, an inter-Allied organization was set up to buy for the Allies in common and to ration supplies. In the last year of the war France met her needs to a substantial degree by the fixation of atmospheric nitrogen; but though a plant for this purpose was begun in Great Britain it never reached the production stage.

*Trench Warfare.*—The stabilizing of the western front led to the employment of a great variety of engines of war subordinate to the artillery, such as mortars, hand grenades, etc., some of which were designed and even produced at the front. These weapons gave great scope for inventive faculties, while the implements themselves did not require the same degree of accuracy as artillery or aeroplanes. Hence they provided an outlet for engineering capacity which was not suitable for more exact munitions, while it enabled civilian enterprise to make substantial contributions on the side of design. The trench warfare department of the Ministry was in fact organized on the principle of setting "design" and "production" side by side. It produced a large number of products which it offered to the army, of which three are of outstanding importance. (1) The first was the Stokes mortar, which was manufactured and sent to the front in spite of a very lukewarm reception by the military authorities. In this case the Ministry proceeded in advance of the sanction of the War Office, but the weapon won its way and became part of the standing equipment in the latter years of the war. (2) The department in the autumn of 1915 experimented with shell filled with lachrymatory gases, and, in the spring of 1916, with poison gases of various kinds. The most powerful of these was at first withheld from use by the army, as the Government was unwilling to go farther in

this respect than the Germans; but the experience of the campaign of 1916 finally removed any scruples of this kind. A notable achievement of the trench warfare department in this field was the development of the cast-iron shell as a container for poison gas. This device avoided making an additional call upon the limited supplies of shell steel, and as it could be opened by a less violent explosion than was required with a steel shell there was less likelihood of destroying the properties of the gas and dissipating it too widely. By 1917 the proportion of chemical-filled shell to H.E. shell was rapidly increasing, and as it finally grew from being a small supplement into an integral part of the ammunition programme, the filling of chemical shell was ultimately taken over by the ammunition filling department. In the autumn of 1918, 20% of certain natures and 12% of others were filled with chemical, and the percentage in 1919 would have been immensely greater. (3) During 1916 the department equipped the army with shrapnel-proof helmets, which rapidly became a regular part of the soldier's equipment.

*Tanks.*—Another feature of Mr. Lloyd George's administration was the commencement of the manufacture of tanks. The design of the first tank was developed (*see* TANKS) by an Admiralty committee and tested before several members of the Cabinet in Feb. 1916. The design was favourably reported upon by the military representatives present, and a special department was created in the Ministry under Col. Albert Stern to manufacture these new weapons. The secret was well maintained, in spite of the special priority in regard to labour and materials which was given to the manufacturers during 1916. Tanks were first used in the field in Sept. 1916, and thereafter their production assumed its normal place among the other departments of the Ministry.

*Other Activities.*—During Mr. Lloyd George's administration steps were taken to establish a general system of priority not only in regard to machine tools and the use of raw material, but also in all the work done in engineering and chemical factories; but the carrying-out of the scheme in full belongs to a later date.

*Foreign Purchases.*—Within a month of his appointment Mr. Lloyd George sent Mr. D. A. Thomas (later Lord Rhondda) to the United States and Canada to report upon the progress of munition output in America. Mr. Thomas reported that although the commission paid to Messrs. J. P. Morgan & Co. seemed high the work was being well done and he recommended no modification in the arrangement. In Dec. 1915, Sir Ernest Moir was sent to America to exercise a general supervision over deliveries. An organization was set up in New York which kept track of output, followed goods through to port, and reported progress to the Ministry. This organization continued in existence until the end of the war, but became part of the British mission in the United States when America joined the Allies. In Canada Mr. Thomas found an organization in being under Gen. Sam Hughes, the Canadian Minister of Militia, though Gen. Hughes had no direct control over British orders. Subsequently the Canadian Pacific Railway were made agents for the British Government, and their organization developed into the Imperial Munitions Board, which exercised the functions of the Ministry of Munitions in Canada except that of inspection, which remained under an officer in Ottawa responsible to the head of the inspection department in Great Britain.

*Financial Control.*—At the commencement of the war it was evident that in the existing state of uncertainty it would be impossible for Parliament to retain control over the details of expenditure, and from Aug. 6 1914 onwards the money for carrying on the war was voted in the form of unallotted votes of credit, whose distribution was placed in the hands of the Treasury. The latter department, however, at once recognized that it was impossible for the spending departments to submit detailed proposals, and it therefore abandoned the machinery by which it normally sanctioned expenditure. This relaxing of control applied first to direct expenditure for the war, but was soon extended to cover advances to contractors, etc.

When the Ministry of Munitions was formed, similar powers were necessarily conferred upon the Minister except as regards the salaries of officials. Nor was it possible for the finance officers of the Ministry to control expenditure in the sense that they could exercise any influence upon the volume of orders to be placed. It has been stated that at the outset the Ministry placed orders largely in excess of War Office requirements in order to increase munition-producing capacity, and at a later date the Ministry discussed the character of the programme put forward by the War Office from the standpoint of the balance between various demands, the extent to which they could be met from stock, or the limitations imposed by lack of materials, tonnage, labour or other limiting factors. But except as regards the limit of money available for foreign purchases, financial considerations did not, in fact, govern the munition programme.

The task of the financial officers of the Ministry, under the assistant financial secretary (Sir Hardman Lever), was, therefore, confined to ascertaining that the public funds were spent as economically as possible. The limitation of contractors' profits to a large extent suspended the normal stimulus to reduce costs of production, and the first and most important enterprise of the finance department of the Ministry was to develop and impose upon contractors an adequate system of "costing" and cost-accounts. These were developed during the first few months of the Ministry's existence, and enabled the officials of the Ministry to negotiate successfully considerable reductions in prices. This costing system, together with the rapidly increasing efficiency of production through experience of manufacture on a large scale, quickly produced substantial reductions in price as compared with the original sums paid for all classes of munitions. In Aug. 1916 it was claimed by Mr. Montagu in the House of Commons that the Ministry had already saved by this means £20,000,000 on home shell contracts alone and that American and Canadian prices for shell had been reduced 15% and 12½% respectively.

*Design.*—A most important expansion of the functions of the Ministry took place in Nov. 1915, when the design department of Woolwich was transferred to the Minister. A new inventions board had already been instituted in the Ministry, but this did not deal with established service articles. It had for many months been a subject of complaint, by those controlling production in the Ministry, that the design department was still working on pre-war traditions and was not sufficiently in touch with the requirements imposed by methods of mass production, nor was it drawing sufficiently upon the experience which was being gained by those actually engaged in this production. The War Office quite properly attached the very greatest importance to questions of design and the accuracy limits in specifications which the safety of the army made necessary, and were unwilling to release control of this department. The matter, however, was decided by the Prime Minister (Mr. Asquith) in favour of the Minister of Munitions, the transfer was made, and it was laid down that the Army Council should inform the Minister in general terms of the qualities required in a specific supply, that the design department under the Minister should submit its results to the War Office, and that the latter would then indicate the amount of its requirements. The officer in charge of design under the Minister would, however, be responsible for approving the specifications for manufacture. This officer, who in the first instance was also given charge of the inspection staff, thus took over the duty of laying down the standards of inspection.

The work of this department during the first six months after its transfer to the Ministry was of an exceedingly difficult character, for it had to solve the problem of successfully detonating artillery shell filled with the new high explosive (amatol).

The transfer of this department, which was put under a military officer with war experience (Maj.-Gen. Du Cane), had the important consequence of creating direct contact between the Ministry and the army in the field, and so enabled the behaviour of the new munitions under service conditions to be known in the workshops.

*The Somme Battle.*—The first period of the Ministry's history ends with the opening of the battle of the Somme. The output of artillery and of ammunition, so long delayed by one difficulty after another, had at last permitted the army to accumulate a substantial stock of shell and to dispose of an artillery equipment with which it could match the standard of expenditure set by the Germans at Verdun. But the stock had only begun to accumulate in the preceding six weeks; and as the preliminary bombardment (which could be heard from the English coast) continued day after day, the rapidly dwindling stock was watched

with growing anxiety. When the troops went over the parapet, and while the ground was being consolidated and the guns brought up, there was a momentary respite, but within a few days the barrage broke out again, and before the end of July the army was living from hand to mouth upon the incoming supply from Great Britain. So far as all the heavy natures were concerned, practically the whole of this came from a single filling factory. The fear of an untoward accident to Chilwell or of an interruption to the cross-Channel service was thus added to the normal worries of production and transport. Fortunately, however, everything went according to plan, and the supply steadily grew until the winter brought the offensive to an end.

This achievement was not the first fruits of the formation of the Ministry of Munitions. The army had been living for months past on munitions supplied on previous War Office orders; but these orders would not have materialized had it not been for the help rendered by the Ministry to War Office contractors, in technical matters (gauges, drawings, etc.), in supply of materials, and in control of the labour supply, recruiting, etc.

At the end of 12 months, however, the larger plans initiated by Mr. Lloyd George began to bear fruit and became one of the dominating factors in the war. From the middle of 1916 onwards, there was never a general shortage of munitions, and the special emergencies which arose from time to time were met with increasing facility, as the enormous industrial organism which had been set in motion during this first year became more responsive to control.

*Centralized Administrative Control.*—The second year of the Ministry of Munitions (Mr. E. Montagu becoming Minister in July 1916, and Dr. Addison in Dec. 1916) saw a very considerable readjustment of and increase in the artillery and ammunition programmes of the Ministry as a result of experience in the battle of the Somme. The increased artillery demand naturally involved consequential increases in the ammunition programme, but in Sept. 1916 the army sent in a demand that the *ration* of ammunition per gun should also be increased. It was found that the 18-pdr., which at one period was thought might even be superseded altogether, had functions of supreme importance in furnishing the "creeping barrage," in following up before the "heavies" could be moved, and in shelling the enemy as soon as he left his permanent entrenchments.

The daily ration was therefore raised to 50 rounds per gun per day, while the 6-in., 8-in., and 9·2-in. howitzers, whose rations had been 20, 15 and 12 rounds respectively, were raised to a uniform 30. Though these increases added 50% to Mr. Lloyd George's programme, they did not involve any changes in manufacturing policy. They did, however, call for more complete control over materials and processes subsidiary to the ammunition programme, and made necessary increasingly drastic restrictions of non-war work by means of priority certificates, while the growing shortage of labour involved a constant extension of the principles of dilution. These changes involved a tightening of the centralized control of the Ministry over industrial conditions, and made it increasingly difficult for private industry to continue or for other departments to get their contracts fulfilled. It was largely on this account that the Ministry took over a number of additional services, of which the chief were the supply of aircraft, railway material, agricultural machinery and motor vehicles, the last of which was placed in the charge of Sir Albert Stanley.

When the Ministry took over the supply of aircraft, which was placed in the hands of Sir William Weir, the supply of aeroplanes was at the rate of 675 per month and of engines 721 per month. These figures rose to 1,117 and 1,083 respectively per month in the next five months, as new firms came into production and the difficulties with materials were overcome. For the rest of the war, however, it was necessary to give a very high priority to aircraft production, particularly with regard to skilled labour, although the novel character of the work and its consequent freedom from restrictive trade-union practices permitted female labour to be introduced from the outset to a greater extent than in other sorts of munition work.

The progress of "dilution" generally throughout this period is shown by the fact that while in July 1916 employers reported that 336,000 women had replaced men, in July 1917 654,000 women had replaced men. In Government establishments, which had only employed 2,000 women before the war, 69,000 women had replaced men by July 1916 and 191,000 by July 1917.

*Control of Steel and Other Materials.*—The development of the steel department into one of the most vital sections of the Ministry belongs to this period. Prior to the formation of the Ministry of Munitions the War Office had enlisted the services of a steel expert (Mr. McLellan) to assist them in buying the multitudinous variety of products covered by the contracts department, and in the spring of 1915 the Government bought, on behalf of the Sheffield trade, considerable quantities of Swedish bar iron which they held as a reserve against the possibility of Swedish supplies being cut off. Action had already been taken regarding some of the more rare metals used for ferro-alloys, an arrangement having been made, for example, by the Government to take all the wolfram of the Empire until after the end of the war. But in the first year of the Ministry's history the steel problem was not of critical importance, and the steel section was a branch only of the materials department, separate sections being organized to deal with high-speed and carbon tool steel and with metallurgical coke. In the spring of 1916, as the shell factories began to get to work, and the demand for shell steel to assume large dimensions, three aspects of the steel problem came to the front: namely, the necessity for an increase in the total steel production of the country, the restriction of commercial or less essential war uses of steel, and the regulation of prices. The first scheme for increasing the steel plant was prepared in March 1916. In June 1916 plans for developing pig-iron production by converting and modernizing old blast furnaces and building a few new ones were prepared, while in May 1916 the first control order fixing the maximum prices of iron ore, pig-iron, steel, coke, bricks, etc., was passed. These arrangements were supplemented by the placing of orders for shell steel in the United States, and in June 1916 a representative was sent to that country to arrange for supplies. During this first year some assistance in meeting demands was obtained by a modification of the War Office's specifications. By April 1916 the Army Council had approved the use of steel in shell containing up to ·07% of sulphur and phosphorus. This figure was subsequently increased to ·08%. One other problem which had given rise to difficulty was the supply of foreign ore, as a result of the increase in freights. A committee of ore merchants was summoned in the spring of 1916, and decided upon a uniform freight basis from Bilbao to Great Britain of 17s. per ton, an official ore broker being appointed to take entire charge of chartering ore tonnage. The centralization of chartering had a wholesome effect, and though the price subsequently rose to 38s. the demoralization of the market was prevented. Such was the position when in Aug. 1916 it was decided to form a separate steel department under Sir John Hunter.

The first action of this department was to press forward the plans already prepared for building new steel works and bringing new blast furnaces into operation. These programmes were subsequently enlarged at various times, and ultimately amounted to 166 new steel furnaces and 22 new blast furnaces in addition to the 40 old blast furnaces modernized. At a later date large rolling-mills were commenced, chiefly for increasing the supply of steel plates for ships, tanks, etc., and from time to time substantial improvements were made in the equipment of existing rolling-mills. In all these developments the Government shared the financial burden, not by direct subsidy but by allowing firms a deduction from their excess-profits-duty payments. A substantial percentage of these extensions were completed before the end of the war, but the programme was considerably delayed by insufficient labour and by difficulties in securing materials.

The problem of foreign ore supplies became increasingly difficult. The new department dissolved the existing committee and created a section for dealing with this problem. The purchase of Spanish ore remained in the hands of merchants, but they had

to obtain the permission of the Ministry before placing orders, and thus in effect, though not in form, the purchase was centralized. This action, together with the fact that Germany was no longer in the market, prevented the price of ore in Spain from being unduly raised. Freight rates, however, and the cost of insurance rose to enormous sums; but as the Government bore the excess over the official rate, ore was delivered to British works at a fixed price. This became an important factor in stabilizing the price of steel. As regards Swedish ore large quantities were bought, and supplied to British makers.

The difficulty in securing shipping from Spain and the Mediterranean led to two internal developments. (1) The Cumberland ore mines, which were the only substantial source of non-phosphoric ore in Great Britain, were taken over on the basis of a guarantee to the owners and developed to their maximum output. (2) Under the most favourable conditions, however, no more than a small proportion of acid steel from British ore could be expected. A great effort was accordingly made to develop the manufacture of basic at the expense of acid steel, which had hitherto constituted the larger part of the output of Great Britain. This involved in the first place an attempt to increase the output of the low-grade phosphoric ores of Oxfordshire, Northamptonshire and elsewhere, and in the second place a modification in the programme of steel works extensions, which first had been planned mainly for acid steel.

This question of basic steel, though a technical one, was potentially of great political importance. In peace-time, Great Britain had been content to be dependent on foreign sources of relatively high-grade ore for more than half her steel. The problem in 1916 was whether it was either possible or desirable to become self-dependent in this vital matter. There was much to be said for and against each of three possible courses:—(1) making basic steel from low-grade British ore, (2) making acid steel from imported ore, or (3) importing pig-iron or steel from America. The difficulty of importing ore which required a large tonnage on a submarine-infested area was obvious; but the use of low-grade British ore involved a larger consumption of fuel and therefore of man-power in the coal-mines, and an increased congestion in internal railway transport. Imported American pig-iron, on the other hand, utilised neutral labour and economized tonnage, since two tons of Spanish ore are needed to make a ton of pig-iron, but until America came into the war the difficulty of financing purchases and the desire not to become too dependent on the United States caused the Ministry to persevere with home supplies, and even after America joined the Allies the policy could not be materially changed, owing to the large scale of the war demands of the American Government, which left little margin for export. Hence the production figures (Table II) show a steady development in basic output.

TABLE II.

| | Acid Steel Output (Ingot tons) | Basic Steel Output (Ingot tons) |
|---|---|---|
| 1913 | 4,860,000 | 2,804,000 |
| 1914 | 4,478,000 | 3,357,000 |
| 1915 | 5,111,000 | 3,439,000 |
| 1916 | 5,468,000 | 3,523,000 |
| 1917 | 5,772,000 | 3,945,000 |
| 1918 | 4,992,000 | 4,547,000 |

The total of 36,700,000 ingot tons of steel for the four war years 1915–8 (toward the production of which there were imported 26 million tons of ore and over ½ million tons of pig-iron) represents about 28 million tons of finished steel, to which must be added 2½ million tons of shell steel imported from the United States and Canada, and a million tons of general steel.

In Nov. 1916, a control order restricting steel consumption for less urgent uses was passed, under which the department was entitled to obtain itemized returns of steel deliveries from every works, and to insist that the orders in hand should be carried out in order of urgency. These returns showed how much steel was being used for each branch of war production; and although at first it was difficult for the various departments of the Government to reduce their demands to a fixed programme and to convert these demands into terms of steel, a system was gradually evolved in which it was possible to balance deliveries against requirements. From July 1917 onwards steel allocations were made at monthly meetings of departments presided over by the controller of steel production.

By this time, however, the balance of needs had been substantially altered. The shell programme had been in effective operation for nearly two years. Stocks of empty shell and of shell steel had accumulated, the orders placed in America had materialized, and it was now possible to deal with the supply of ammunition without providing large margins for contingencies; hence the actual monthly allocation was substantially reduced. On the other hand, a very urgent demand for steel for shipbuilding had arisen, and with increasing demands for tanks, aircraft, military railways and other needs the supply of shell steel dropped to a relatively minor position. The figures for the allocation of steel for the first six months of 1918 (Table III) show the balance between the various departments.

TABLE III.—*Steel Programme for First Six Months of 1918.*
(*Weekly average in tons.*)

| | | |
|---|---|---|
| Admiralty (mainly plates and sections) | | 37,076 |
| War Office Contracts Department | | 10,018 |
| Ministry of Munitions | | |
| Explosives | 556 | |
| Guns, large | 2,760 | |
| Machine-guns and S. A. | 900 | |
| Trench warfare | 924 | |
| Mechanical warfare | 3,480 | |
| Mechanical transport | 1,376 | |
| Aircraft | 3,536 | |
| Steelworks extension | 1,428 | |
| Factory construction | — | |
| Machine tools and cranes | 1,176 | |
| Railways, U.K. | 4,536 | |
| Railways, overseas | 4,924 | |
| Electrical power supply | 676 | |
| Total M. of M. | | 26,272 |
| India Office | | 492 |
| Other Government Departments and Priority | | 19,804 |
| Allies:— | | |
| France | | 6,940 |
| Italy | | 1,092 |
| Shell steel: | | |
| Great Britain land service and Admiralty | | 21,448 |
| France | | 900 |
| Italy | | 3,360 |
| Tubes | | 7,672 |
| Wire rods | | 4,808 |
| Grand Total | | 139,880 |

The actual realization was fairly close to the estimated figures, but in addition an average of 16,400 tons of shell steel was imported from the United States and Canada.

In regard to prices the Government, after attempting in 1915 to regulate prices by agreement, found that costs were rising to such an alarming extent that it was faced with the necessity either of raising the price of steel, and so altering the basic figure of vast numbers of Government contracts, or of keeping prices fixed and making good the balance to manufacturers in the form of direct or indirect subsidies. The change in prices would ultimately have been very large, as the subsidies finally amounted to no less than £10 per ton on steel made from imported ore. Of this sum, ocean insurance amounted to £5. The event thus justified the decision of the Ministry to adopt the policy of subsidies, for otherwise it would have been faced not merely with the readjustment of numberless contracts, but also with a rise in the general level of prices, involving increased middlemen's profits, wages variations, etc. Moreover, the Government was itself directly or indirectly the purchaser of 98% of the total produced, and, except as regards freight, the increases in steel cost were largely caused by wages advances, which were to a substantial extent controlled by the Government itself. The policy once started involved controlling the materials for production, including ore, coke, pig iron, scrap, ferro-manganese, and magnesite, fire, and silica bricks. Increases in wages in the steel works themselves were met by paying subsidies direct to

the manufacturer, but the bulk of the subsidies were paid not directly to steel manufacturers but to shipowners and mine-owners, and in bearing the actual cost of submarine losses at sea. The total amount paid directly or indirectly as subsidy to steel production costs in 1918 reached 45 million pounds sterling.

The only other way in which the stabilization of prices could have been obtained was for the Government to have bought the whole output of iron and steel, and to have sold it to the user; and if the complete character of the control had been envisaged at the outset it is possible this plan would have been adopted; but as control was at first only partial, while the maintenance of private commerce remained important, it was impracticable.

The case of steel is the most representative example of the numerous controls exercised by the Ministry over a wide field, touching the economic life of the community at many points.

Before the Ministry came into existence, some measure of regulation had been adopted in the case of several non-ferrous metals and chemicals. At an early stage in 1915, for example, the Government purchased the whole output of wolfram (the ore used for making tungsten, which is the alloy used in high-speed steel) from imperial sources. The list was added to continuously throughout the war, until at the Armistice it included aluminium (the demand for which enormously increased owing to its use in aircraft, in fuzes, and as a chemical element in smoke powder), antimony (used as an alloy of lead for making shrapnel bullets), chrome ore (the material for the alloy in chrome steel), copper, brass, lead, nickel (for nickel steel and rifle bullets), mica (for magnetos), platinum, potash, resin, shellac, tin and zinc. The long list of the explosives department included acetate of lime, acetic acid, acetone, glycerine, bleach, chlorine, ether, benzol, coal tar, creosote, nitrate, pyrites and sulphuric acid. The new process for making cordite, which was developed at the Gretna factory, was one of the main causes which brought alcohol under control, and ultimately stopped its production for non-industrial purposes; while the control of sulphuric acid, together with the scarcity of nitrate, quickly brought the whole supply of fertilizers within the domain of the explosives department, since control of one or two materials inevitably leads to the control of competing materials. Thus the department became responsible for the supply of superphosphates and basic slag, nitrate and sulphate of ammonia, and potash.

Several of these commodities differed from the case of steel in the fact that the article was imported on a large scale in the form in which it was commonly sold in England. Regulation, therefore, commonly started in two ways: the fixing of a maximum price and the control of importation by licence. The Government early exercised a large influence on the market by reason of very large contracts which it placed abroad, but these were not always sufficient to give adequate control. Hence orders were made under D.O.R.A., giving the Government the right to commandeer all imports on private account. Even this was not always sufficient, since the existence in the country of a large stock of material made allocation difficult and created a small but free market which had a disturbing effect on price. Hence the further step was necessary of prohibiting purchase and sale except under licence. Finally, in all cases where home production was a substantial element, as for example in the case of alcohol, glycerine, etc., the Government commandeered the whole of the internal output. Certain cases, however, such as pyrites, followed the steel precedent, since the stabilizing of the price of sulphuric acid meant that, as the cost of transport and insurance of pyrites from Spain increased, the Government had to bear a large part of the cost of the material.

The period under consideration marked the transition in the great majority of cases from the looser form of control by maximum price to the more complete regulation of all dealings in the commodity and the commandeering on Government account of total available supplies.

*Foreign Orders and American Intervention.*—When it was decided to place new heavy-shell orders abroad, considerations of finance, together with the desire to avoid becoming too dependent on a country which at any moment might ban the export of munitions, led the Ministry to place as large a proportion of orders as possible in Canada. The failure of the new rifle plants erected in 1915 to make delivery in time to relieve the rifle shortage led to special negotiations for reduction in these contracts, and arrangements were ultimately entered into, under which the total to be delivered was reduced from 2,500,000 to 1,200,000. This, together with other orders, meant that in 1916 the British Government was buying large quantities of material but not much finished munitions from America. When America entered the war, representatives of the Ministry accompanied Mr. Balfour to the United States with the object of giving the U.S. Government the benefit of British munition experience, endeavouring to coördinate the programmes of the Allies, and arranging for any change that might be called for in the organization of the munitions office in America. The American departments were not in fact sufficiently organized as to personnel or duties to enable these objects to be carried very far at that date. In May 1917, Messrs. Morgan gave notice to terminate their commercial agency, and offered to place their organization at the disposal of the U.S. Government. As a temporary arrangement they offered to continue to place orders for the Allies at a reduced commission, but it early became evident that every order would involve negotiations with the Government for financial approval as well as for the necessary priority and export permits. It was clear that these duties could not be appropriately undertaken by an American organization, and on the recommendation of the Balfour mission a British munitions representative was sent out to take charge of a mission in Washington, whose duty would be to carry on negotiations with the American Government for the necessary supplies. This officer subsequently became part of the American war mission under Lord Northcliffe.

*Assistance to Russia.*—In the autumn of 1916, serious attention was devoted to the possibility of remedying the disparity in the material resources available on the Russian compared with the western front, the need being emphasized by the arrest of the successful offensive of Gen. Brusilov as soon as his troops came up against fortified positions which could only be overcome by heavy artillery. From the beginning of the war, Lord Kitchener had made great efforts to persuade the Russians to place orders abroad, and direct assistance in this task both in England and America was subsequently given by British organizations and British credit. But the possibility of direct material assistance was very limited. Russia was a non-industrial country taking part in a war which was being largely fought by mechanical appliances, and in particular, on the vast extension of the eastern front, by modern means of transit. Russia was ultimately defeated by the failure of her inadequate railway system, which was called upon (1) to provide mobility for the troops at the front, (2) to bring food from the interior of Russia for 15,000,000 men and large numbers of horses normally living on the local produce of the soil, (3) to supply coal and steel from the Caucasus to the munition areas of Petrograd and Moscow which normally got supplies *via* the Baltic or by the Polish frontier, (4) to carry imports from the ice-bound ports of Archangel and Vladivostok. From Vladivostok it required 120 locomotives to maintain one train a day to Moscow; and though new rolling-stock and engines were put on rail in the Far East, by Christmas 1916 there had accumulated 600,000 tons of war material, including tens of thousands of tons of barbed wire, though many miles of the front had no wire defence at all.

The munitions representatives who accompanied the Allied mission to Russia in Jan. 1917 found that, in spite of the completion of the railway from the ice-free port of Murmansk to Petrograd, the ports and railways of Russia could not deal with more than 3,500,000 tons of imports (including coal), compared with minimum demands for 13,000,000 tons. A careful programme based upon the former figure was drawn up, including a substantial supply of heavy artillery and aeroplanes, and a permanent mission was stationed in Petrograd to assist in transport and in the training of personnel, but the revolution prevented the programme from being carried out.

*Internal Developments.*—During this year, efforts were made to improve the internal organization of the Ministry, among whose various parts there was still a lack of coördination. Moreover, the increasing functions had led to still more heads of departments having direct access to the Minister. Mr. Montagu endeavoured to deal with the problem by setting up a committee whose chairman (Sir Arthur Duckham) and vice-chairman (Sir James Stevenson) were relieved of departmental duties; but its powers were purely advisory. At the same time a weekly meeting of heads of departments was inaugurated and continued until the summer of 1917. This was of value in giving all departments a knowledge of general policy; but the numbers were too large for it to be an effective instrument of administration.

More important developments were inaugurated in financial administration, in two directions. The first was the overhauling of all the past accounting transactions of the Ministry, with the view of recovering money that had been temporarily lost through the confusion and deficiencies of the earlier system of records. This bore fruit in "recoveries" to the amount of some £39,000,000. The second was the reconstitution of the accounting system on a commercial basis for the future, by substituting double-entry for the old single-entry system, in use before the war in nearly all Government departments. Since the method of departmental bookkeeping was dictated by the prescribed form of accounts rendered to the Treasury and Parliament, this reform led incidentally to proposals for a remodelling of the public accounts themselves. By 1917 the financial staff of the Ministry had established a system of contract-control by means of cost accounts.

Early in 1917 the control of the inspecting staff was reorganized as an independent department under Sir Sothern Holland. This period also saw a great increase in the size and duties of the priority department, under Sir Edgar Jones. The staff of the Ministry, which had risen to 5,000 under Mr. Lloyd George, rose to 13,000 by July 1917.

*Inter-Allied Coördination.*—The third and culminating period of the Ministry of Munitions (Mr. Winston Churchill being Minister from July 1917 to Jan. 1919) saw certain important though not fundamental changes in programme. The chief of these were growing aircraft demands, accentuated by the campaign of the Independent Air Force against German industrial centres; a sudden enlargement of the tank programme as a result of their successful employment in the attack on Cambrai in Nov. 1917; and, thirdly, the efforts to emulate the Germans in the production of mustard gas, and to find, if possible, new and more effective poisons.

Further, during 1918 plans were far advanced, in preparation for the 1919 campaign, for increasing the range of an offensive, (*a*) by adapting the caterpillar principle to the movement across country of troops and stores on a large scale, and (*b*) by entirely re-equipping the army with longer-range field and other artillery. These measures were carried out by adapting rather than by enlarging the munition-making resources of the country. Indeed, the adequacy of the supply was put to a severe test in March and April 1918, when the army lost 1,000 guns and 100,000 tons of ammunition in the retreat from St. Quentin, in addition to losses resulting from the intensive attacks made upon British munition dumps in France by bombing aircraft. The artillery and ammunition losses were made good by May, and only in the case of small-arms ammunition, the expenditure of which in machine-guns increased to quite unexpected figures, was any anxiety experienced.

This phase of munition history corresponded with the unrestricted submarine campaign, the active participation in the war by the United States, and an increasing shortage of man-power. It was, therefore, marked by increasing efforts to economize and coördinate effort, (*a*) within the Ministry, (*b*) between the Ministry and other British departments, and (*c*) between Great Britain and the Allies.

*Departmental Reorganisations.*—Mr. Churchill's first task at the Ministry was to deal with organization. The internal mechanism had never developed on a considered plan, but had been determined partly by personal considerations and partly by the kaleidoscopic changes in the relative importance of various activities as the drama of the war unfolded. Mr. Lloyd George's administration was a period when half a dozen departments of supreme importance were feverishly urging on production in a new field under new conditions. And the business men in charge of them utilized to the full their right of direct access to the Minister—thus making organization extremely difficult.

The complexity became much worse during the next period, as duty after duty was imposed upon the Ministry, and as the task of carrying out the old ones involved control in new directions and the creation of fresh administrative branches. Hence, by the summer of 1917, the number of departments had increased to over 50, and although the machinery was in existence for coördinating the programme itself, there was not sufficient coöperation or clear definition of responsibility between the departments. Various attempts had been made to meet this difficulty—as, *e.g.* by the proposal to attach to the Minister one or more staff officers who would act as liaison officers between the departments, many of which were housed at some considerable distance from headquarters. A more promising scheme was to increase the number of parliamentary secretaries and make all departments report through one or other of them. But this scheme broke down through the complications still caused by exercise of the right of direct access to the Minister on the part of the business heads.

Mr. Churchill solved the problem by the creation of a Munitions Council, consisting of the Minister, parliamentary secretaries and 12 members, including the secretary to the Ministry. Their duties were to deal in the first instance with all matters requiring decision in the departments entrusted to them; and although the heads of departments in theory retained the right of access to the Minister, in practice it was not exercised and the members of Council became in fact the heads of groups of departments. The reform was accompanied by the rehabilitation of the permanent civil servant. The position of the secretary was strengthened by insistence that papers should pass through his hands to the Minister, and still more by the attachment to each member of Council of a civil servant called a secretarial officer—whose duty was to see that the procedure worked smoothly and uniformly. This machinery came into being and worked with surprisingly little friction.

But in fact the Council did not often meet as such, its work being to a large extent done by a standing "coördinating" committee of the Council, which dealt with all matters arising out of the programme and its execution. A second standing committee of the Council dealt with and prepared plans for demobilization, while matters which did not fall within one or other of these spheres were dealt with by Council committees appointed *ad hoc.*

The organization of the Munitions Council in its final form was as follows:—

F.—Finance, contracts, controlled establishments finance, munitions works board, lands branch, central stores, salvage (Sir Gilbert Garnsey).

D.—Design, inspection, inventions (Gen. Sir Francis Bingham).

S.—Iron and steel production, factory construction (Sir John Hunter).

M.—Non-ferrous metals, scrap, railway material, optical munitions, potash, railway and sea transport of munitions and material (Sir Ernest Moir).

X.—Supply of explosives, propellants and chemicals (Sir Keith Price).

O.—Supply of artillery, gun ammunition, rifles, machine-guns, small-arms ammunition and trench-warfare supplies. Engineering department (Sir James Stevenson).

A.—Aircraft (Sir Arthur Duckham).

W.—Warfare, tanks, poison-gas, etc. (Gen. Seely).

L.—Labour regulation and supply (Sir Stephenson Kent).

Sec.—Secretariat, staff and establishment, legal department, etc. (Sir William Graham Greene).

R.—Requirements and statistics, American department, Allied requirements (Mr. W. T. Layton).

Allies.—Head of Paris office and one of the British delegates on Inter-Allied Munition Council (Sir Charles Ellis).

In addition the master-general of the ordnance (Gen. Furse) was made an honorary member representing the War Office.

At this stage of the war, coördination of the efforts of various departments of state was even more important than internal reorganization. The British Ministry of Munitions never absorbed the purchasing sections of the Admiralty; and the predominant need of naval supremacy, strengthened by the traditional rights of the senior service, had enabled naval requirements to retain a nominal priority over land requirements. This did not greatly affect munition output when once the munition movement was in full swing—except on occasions, notably, when a sudden decision was made to mount two guns on every merchant ship; when the losses of ships at sea placed the shipbuilding programme in front of all other demands and by its call upon steel prejudiced other branches of production; and to a less extent after the battle of Jutland, when the decision was made to replace the whole existing naval ammunition supply.

In the case of seaplanes, and a few articles connected with the anti-submarine campaign, anti-aircraft bombs, etc., the Ministry supplied naval as well as army requirements. But the Ministry did not supply the main needs of the Admiralty; and the plan of forming a single Ministry of Supply for both services, including all the goods supplied by the Army Contracts Department, though much discussed when Mr. Churchill came to the Ministry and though recommended by a Treasury committee, was never carried into effect. Moreover, control was gradually developed by the Ministry of Food, and by the mines, timber, paper and other departments, which still remained under the Board of Trade, dealing with various spheres of economic life. There was also a continued demand from the army for specialists to run the repair services, workshops, etc., which were built up behind the front.

Thus there arose keen competition between departments for man-power, for tonnage and for finance (especially dollar credits in the United States and Canada). There also remained the question of the order of priority of work to be done. But experience had proved that no absolute "priority" could be given to any single activity. The word continued in constant use until the end of the war, but in fact the increasing strain upon economic resources, combined with the greater accuracy of demands and forecasts, meant that the conception of placing demands in order of importance was largely superseded by the plan of rationing economic resources. Each of the three factors mentioned was dealt with by a Cabinet committee, which in one case became the province of a new Ministry—that of National Service. In the case of finance the allocation of American dollars was taken out of the hands of the Treasury and assigned to a standing committee called the American Board—an interdepartmental committee under the presidency of Mr. Chamberlain, who with Lord Buckmaster represented Great Britain on the Inter-Allied Committee of Finance. The problem of tonnage also passed out of the hands of a periodical meeting of departmental officers under the Parliamentary Secretary of the Ministry of Shipping into the purview of a Cabinet committee, and the programme so approved was coördinated with that of the Allies by the Inter-Allied Maritime Transport Council.

So far as they affected munitions, the three factors were intimately connected. It was cheaper to manufacture at home than to buy abroad, and a given amount of dollars would carry a larger programme if spent on raw material than if spent on finished articles. But the tonnage needed to import materials was greater than that required for importing articles such as manufactured explosives or ammunition, while there was obviously a saving in British man-power by buying the finished product. On the other hand, munition capacity at home was in a more highly advanced stage of development than in America, and was quickly adaptable, whereas British orders in America had to compete with the enormous programme of the U.S. War Department. Moreover, the reserve of man-power in the United States was intact, and it was evident that the most rapid and effective way in which America could make her weight felt in the world contest was to get that reserve into the field, with the help, if necessary, of British munitions and equipment. The balancing of these considerations, which occupied much of the time of Ministers during the last 18 months of the war, thus broadened out into the problem of coördinating the whole Allied effort. But the final decisions did not radically alter the proportions of British munitions production.

*Man-power.*—As regards man-power, 53,000 men were withdrawn between March and Nov. 1917 for the army from munitions work, by a continuous process of substitution and dilution without diminishing production. As a result of the German offensive in the spring of 1918, which created a man-power crisis and led to the raising of the age limit for general recruiting, it was decided to make an immediate "clean cut" in the munition factories of all men of 19 and 20 regardless of the nature of their employment, and to take all men of 21, 22 and 23 within a short period. A hundred thousand men were obtained by this plan before the middle of the year; but when the tide of battle turned, Mr. Churchill secured the suspension of the second part of the scheme. Indeed, he secured the release of some of those already enlisted for work upon the new tank programme, for the blast furnaces, and for the manufacture of scientific instruments, etc.

Throughout this period the employment of women steadily increased, and the lack of skilled men was met by pressing them to enroll as war-munition volunteers—thus increasing the reserve of mobile skilled men—and by rationing skilled labour to firms. Protection from recruiting was withdrawn from men not fully employed on skilled work. The embargo on employing more than a certain number of skilled men was at first resisted, and led to a strike at Coventry in July 1918. But the Ministry stood firm and the scheme was carried into effect.

*Tonnage.*—In the autumn of 1917 a drastic cut was ordered by the Cabinet in the import programmes of the different departments, since the Minister of Shipping, taking the best available estimate of losses from the submarine campaign, anticipated that the imports into Great Britain would drop by 10 million tons. The ration to the Ministry of Munitions was reduced from 12 million to 10 million tons, most of which had to be deducted from iron-ore imports. The steel budget was consequently reduced and pressure put upon the departments to minimize their programme. The Minister, however, took the view that, as other supplies might be uncertain and it would be foolish to keep ships waiting for a cargo, he should be allowed to maintain a surplus stock of metals, materials, etc., on the Atlantic seaboard of America ready for shipment at any moment. Owing partly to the success of anti-submarine measures, partly to the success of the policy of concentrating ships on the shortest (*i.e.* the Atlantic) route, and partly because other materials were not ready in time, the actual imports of munition materials during 1918 were at the rate of 42 million tons a year. In the autumn of 1917 an arrangement was made with the United States to supply American ships to convey material needed in Great Britain to replace material used in making goods for the U.S. army in Europe. But this scheme of hypothecating ships to convey particular replacement material was not, in fact, carried into effect, being superseded by the plan of reviewing and allocating the tonnage and material resources of the Allies as a whole through the machinery of the Inter-Allied Transport and Munitions Councils.

The orders for heavy shell placed by the Ministry in 1916, which were delivered during the early part of 1917, gave so large a stock that no further orders were necessary except in regard to 6-in. shell orders, which were placed both in the United States and Canada for delivery in 1918. Apart from this, the main requirements from America were for shell steel, nitro-cellulose powder, copper, spelter, motor lorries and lubricating oil, while as the year progressed substantial orders were also placed for aeroplane spruce, and for Liberty engines. The rate of dollar expenditure, however, in 1918 represented less than half of the maximum reached in the first quarter of 1917, while in Canada the purchases dropped to less than 60% of the maximum reached in the second quarter of 1917.

*Inter-Allied Relations.*—These discussions emphasized the necessity for agreement with the Allies. In the late summer of

1917 the difficulty of financing imports from the United States led to an agreement between the British and French Ministers of Munitions, under which the latter undertook to pay by dollars in America for goods bought in England which involved replacement in American material. Further discussion of the problem, moreover, led the British Minister to insist that the production of shell steel to French specification should cease and that M. Loucheur should buy his shell steel direct from America. France, from a very early stage in the war, had devoted her restricted steel production to the manufacture of more finished products, and had relied on England and America for the overwhelming proportion of her shell steel. The French Minister was anxious to retain some of his supply from European sources as an insurance against an interruption of sea communication; and to meet this difficulty Mr. Churchill agreed to retain a small output of shell steel of French specification. The bulk supply was, however, transferred to the United States. This example illustrates the kind of problem which arose under the conditions at the end of 1917, and which, together with the necessity of coördinating the American munition effort with the Allied needs, gave rise to the formation of the Inter-Allied Munitions Council. Prior to the formation of the British Ministry of Munitions the Allied delegates purchasing in Great Britain on behalf of their respective Governments had been brought together in an international commission under the supervision of an officer of the Board of Trade. This officer and his staff, however, could not keep in touch with the growing supply departments, and their function resolved itself into that of rendering assistance as liaison officers to the foreign purchasing agents in London. In particular their duty was to see that the purchases made were a proper charge against the funds loaned by the British Government to these various countries, and secondly that ships were available for transporting the goods purchased.

When the Ministry of Munitions started, Mr. Lloyd George took an early opportunity of holding a conference with the French Minister of Munitions, and throughout the war such conferences were frequent. In Nov. 1915, at one of these meetings, at which Italian and Russian delegates were present, it was agreed that an Inter-Allied bureau should be formed for the purpose of studying and coördinating the requirements of the Allies. The scheme, however, was never carried into effect, as the Allied nations were not at that time ready to declare the basis of their requirements. In the early summer of 1916 the competition of the Allies in the United States became accentuated, and a few months later it was decided to form a bureau the duty of which was to coördinate the demands made upon New York by the various Ministers of Munitions. The bureau was not, however, sufficiently strongly supported, and it was found that various departments were placing orders without consulting the organization. A third attempt at coördination was made in Nov. 1916, when the campaign of 1917 was discussed in London. At these conferences substantial progress was made in the direction of setting down the complete programme of the different Allies present, and it was agreed that an organization should be set up in Paris to which full information should be supplied, and from which a complete statement of the requirements in the field and the manufacturing requirements of each Ally should be circulated for confidential information to the various Ministers. This organization continued with fluctuating fortunes and with fairly full information about Great Britain and France, but very little about other Allies. Sufficient information was, however, forthcoming to afford a very valuable check upon the demands put forward from time to time by various countries.

Such was the position when a conference was held in Dec. 1917 in Paris to consider the position for 1918. At this conference the European Allies recommended America finally to adopt a European type of artillery, but no definite plan of coöperation emerged from this discussion.

In April 1918 Allied munition officers, including representatives of the American army, again discussed the munition situation in reference to the situation in America, and as a result M. Loucheur, at the suggestion of the British representative, sent out formal invitations for a conference to meet in June to consider a proposition for the constitution of a permanent Inter-Allied Munitions Council, with a standing secretariat and with authority to discuss and make recommendations upon the programme of the various Allies. This Council was organized into sub-committees dealing with artillery, explosives, tanks, aircraft, tonnage, steel and raw materials. This was nominally an advisory body, but as its chief members were the Ministers themselves it was of sufficient authority to take binding decisions and to negotiate with the Inter-Allied Transport Council and the Financial Council of the Allies as to the tonnage and finance available for munitions, and to arrange between the Allies for the allotment of such resources. It thus represented an important link in the final coördination of Allied efforts.

Its existence enabled a check to be put upon the basis for calculating the production programme of the various Allies, while the general survey which it gave enabled it to make a unanimous recommendation to the United States to give priority for French and British shell steel required over steel for American factories, in view of the depletion of British and French reserves, and the necessity of making them good before the 1919 campaign, which might be expected to start early in the new year. Finally, the representative of the American War Department on the Council, when he received instructions that an enormous increase was to be made in the size of the American army in the field, was able to organize a plan which, by using British and French gun-making capacity, would have enabled this enlarged army to be equipped many months earlier than would have been the case by depending upon American factories.

At the Armistice the numbers employed in the Ministry of Munitions amounted to over 25,000, of whom 60% were women.

*Some Munition Statistics.*—The development of the British munition effort may be illustrated by some additional statistics. The most striking are perhaps the expenditure of gun ammunition on the western front. The figures cannot suitably be shown in numbers of rounds, owing to the change from light to heavy shell during 1916 and 1917, and to a limited extent back to light shell when open warfare was resumed in 1918. The best index is therefore weight in tons.

TABLE IV.—*Munition Expenditure on Western Front (in tons).*

* 1st Somme battle.

† Messines, Arras, Vimy, 3rd battle of Ypres, Paschaendale Ridge, 1st battle of Cambrai.

‡ St. Quentin, 2nd battle of Somme, general advance.

Table IV. shows that the expenditure of ammunition reached its climax in the autumn of 1918. More than 10,000 tons a day were fired on 15 successive days, and in the record week ending Sept. 29 3,383,700 rounds, weighing 83,000 tons, were fired.

On Sept. 29, when the Hindenburg line was broken, 943,837 rounds were fired, the cost of a single day's ammunition amounting to £9,871,000.

Table V. further shows the progress of the manufacture of guns and ammunition throughout the war; of the 213,000,000 complete rounds delivered, 126,000,000 were filled in new national filling factories built by the Ministry. Of the empty shells delivered during the war, 28% in number came from British

The classification is that adopted by the Inter-Allied Munitions Council. In the case of Great Britain it includes under "light" field guns (13-pdr. and 18-pdr.), mountain guns (2·75-in. guns and 3·7-in. howitzers), anti-aircraft guns (13-pdr., 3-in. and 4-in.) and tank and other miscellaneous small guns. The medium guns include the 60-pdr. gun and 4·5-in. howitzer. The heavy include the 6-in. howitzer and gun and the very heavy include 8-in., 9·2-in., 12-in. and 15-in. howitzers and guns.

contractors, 35% from national projectile or shell factories or through local munition committees, 12% from the United States and 25% from Canada.

*Trench Mortars and Trench Ammunition.*—When the war broke out, the British army was not furnished with any weapon especially adapted for trench warfare, and in the fourth quarter of 1914 only 12 trench mortars were delivered. The maximum production of trench mortars was attained in the second quarter of 1916 when 2,178 were delivered. The total number of trench mortars delivered during the war period amounted to 19,096 and the output of trench-mortar ammunition to over 17,000,000 rounds. The total number of grenades delivered amounted to 100,103,000, and of aerial bombs to 4,738,000.

Table VI. shows, further, the number of rifles, machine-guns, small-arms ammunition, etc., delivered during the war. Of the 5,316,000 rifles manufactured, 3,954,000 were made in Great Britain, and the army was entirely armed with rifles of home manufacture. The maximum home output of rifles was attained in the last quarter of 1917, when 324,000 new rifles were delivered. A total of 240,000 machine-guns were delivered, and output rose from a total of 211 in the fourth quarter of 1914 to 33,484 in the second quarter of 1918. The total number of rounds of small-arms ammunition manufactured amounted to 9,172,645,000, nine-tenths of which was manufactured in Great Britain.

The number of aeroplanes manufactured amounted to 54,789, the maximum output being attained in the third quarter of 1918. The number of aero-engines delivered was 57,031, the maximum output being attained in the first quarter of 1918. The first tanks were delivered in the third quarter of 1916 and numbered 110. Owing to changes in design, etc., only 40 were delivered in the following quarter and 100 in the first quarter of 1917. The maximum output was attained in the second quarter of 1918, when 507 were delivered. The total number of tanks manufactured amounted to 2,818.

*Mechanical Transport, Railway Material, etc.*—The Ministry became responsible for the supply of motor vehicles on Sept. 1 1916. From this date to the end of 1918 there were delivered 33,000 heavy lorries, 2,500 four-wheel-drive lorries, 4,000 light lorries, 4,700 motor-cars, 1,700 ambulances, 4,100 Ford cars, 1,400 Ford ambulances, 12,000 Ford vans, 2,200 caterpillar tractors, 27,700 motor-cycles, 7,000 motor-cycle combinations and 183 armoured cars.

The Ministry of Munitions became responsible for the supply of railway material in Oct. 1916, and from that date supplied 2,300 m. of 75-lb. rails, 4,200 m. of light rails, 750 standard-gauge locomotives, 800 locomotives for other gauges, 13,000 petrol tractors and 33,000 railway wagons of various types.

*Workers on "Munitions."*—It is impossible to state accurately the numbers engaged on the manufacture of munitions at various dates during the war period, because the term "munitions" has never been strictly defined, nor did the Ministry of Munitions undertake any comprehensive inquiry into the numbers of munition workers. The best approximation to the number of munition workers is found in the reports of the Board of Trade on the state of employment in the various industries, where the number engaged on Government work is also shown. The accompanying Table VII. shows the numbers engaged in Government establishments and on Government work in the metal and chemical trades, which may be taken as broadly covering "munition" work.

It will be seen that between April 1915 and July 1918 the number of males engaged on munitions more than doubled while the number of females had increased tenfold. By mid-summer 1916 more than 80% of the workpeople in the metal and chemical trades were on Government work, and by the summer of 1918 more than 90% were on Government work. No figures are available as to the number engaged on Government work prior to the war, but it is considered unlikely that they could have amounted to more than 50,000.

*Allies.*—During the war, Great Britain kept Italy and France supplied not only with coal, but with substantial supplies of iron and steel, which, until 1918, when the United States

TABLE VII.—*Numbers Employed in Government Establishments and on Government Work in the Metal and Chemical Trades*

| | Males | Females | Total | Percentage to total numbers employed in the metal and chemical trades and in all Government establishments. | | |
|---|---|---|---|---|---|---|
| | | | | Males | Females | Total |
| April 1915 | 1,009,000 | 78,000 | 1,087,000 | 55·9 | 33·5 | 53·4 |
| July 1915 | 1,397,000 | 136,000 | 1,533,000 | 74·0 | 52·8 | 71·6 |
| July 1916 | 1,752,000 | 375,000 | 2,127,000 | 84·0 | 70·8 | 81·4 |
| July 1917 | 1,923,000 | 707,000 | 2,630,000 | 88·0 | 83·4 | 86·8 |
| July 1918 | 2,046,000 | 825,000 | 2,871,000 | 91·2 | 89·4 | 90·7 |

assumed more of this burden, amounted to from 1,000,000 to 1,500,000 tons of iron and steel a year to France and 250,000 tons to Italy. Great Britain also kept France and Italy supplied with benzol, and Italy with T.N.T., picric acid and other explosives. As regards finished munitions there was a certain amount of interchange, Great Britain receiving aero-engines and some anti-aircraft guns from France and motor-cars from Italy, and supplying heavy artillery and ammunition, incendiary and other special small-arms cartridges for use in aeroplanes, and machine-guns. British assistance to Russia took the form almost entirely of finished products, including machinery.

*The Last Stage.*—Under Lord Inverforth, as Minister from Jan. 1919 to March 1921, the last stage was reached. Prior to the Armistice the Demobilization Committee had considered plans for dealing with the situation that would arise when the "cease fire" sounded, and the army in France would suddenly find itself unable to deal with the inflowing tide of munitions. The most difficult problem was to dispose of the daily production of explosives and filled shell from the filling factories. When the Armistice actually arrived immediate orders were given to stop work in these two classes of factories. Some latitude was allowed in the engineering shops, but, as arrangements had been made for paying benefit to men out of work, the rights of the Ministry under the Break Clauses were soon put into operation. Production, in fact, ceased—partly owing to the sudden loss of purpose in munition work and the unwillingness both on the part of the workpeople and of employers to continue making what were obviously useless articles. In the steel works, managers were loth to put material into articles which would clearly have to be put back into the furnaces, and everyone was anxious to get on to peace work. The Finance and Contracts departments did their utmost to come to friendly agreements with contractors in regard to cancellation, and every effort was made to clear the munition material from the shops.

A similar policy of encouraging a rapid return to peace conditions was adopted in regard to the raw materials controlled by the Ministry. Restrictions on importation and on purchase of steel were rapidly removed, and even where large stocks were held by the Government, control over the market was rapidly relaxed. In order that the metal and chemical markets should know how they stood, the stocks in Government hands were published, and in as many cases as possible bargains were made with trade organizations to take over and dispose of these surpluses, which in several cases amounted to two or three years' supply for peace purposes.

It was at first anticipated that the State would have to place substantial orders to enable industry to start, and large orders in particular were anticipated in connexion with the Government's housing scheme. The Cabinet therefore decided that the plan already discussed for converting the Ministry of Munitions into a Ministry of Supply, which should deal with purchases of all kinds for every department of State, including the Post Office, Office of Works, Admiralty, War Office and the Air Ministry, etc., should be carried into effect. The anticipation that large orders would have to be placed was, however, not fulfilled, and as the need for drastic economy in Government expenditure was slowly realized the scheme was dropped.

Immediately after the Armistice the labour department of the Ministry of Munitions was transferred to the Ministry of Labour, and the design department reverted to the War Office. The Ministry was thus left with two great tasks, that of closing up the accounts of the war and that of disposing of the enormous war stores in the hands of the Government. The surplus stores in Great Britain of the fighting departments were transferred to the charge of the Ministry, as well as the large stocks held abroad. At the end of the financial year 1920–1 these remaining duties were transferred to a liquidation and disposals commission under the direct supervision of the Treasury, and the Ministry of Munitions as a separate entity ceased to exist. (G. I. H. L.; W. T. L.)

## II. United States

No accumulation of war materials in excess of the amounts required for the regular army, which numbered 127,588 on April 6 1917, was made by the United States in anticipation of entry into the World War; and the Director of Munitions, Benedict Crowell, subsequently stated that there were no plans in the War Department for the "necessary mobilization of industry and production of munitions, which proved to be the most difficult phase of the actual preparation for war" (*America's Munitions*, p. 18). After the declaration, all of the forces of Government, supplemented by voluntary endeavour of citizens, were turned towards the recruiting and supplying of the national army, which 19 months later (Nov. 11 1918) numbered 3,757,624, of whom 2,086,000 had been transported to France.

| Men in war work | 7,150,000 |
| Women in war work | 2,250,000 |
| Men and women not in war work | 44,350,000 |
| Aged and children | 47,000,000 |
| Total | 105,000,000 |

The total number of American troops placed in the field was larger than could have been equipped with material of American manufacture; the speed in recruiting was made possible by the fact that the great European Allies had in 1917 reached, if not passed, their maximum man-power in the field, whereas their power to produce munitions was unimpaired and growing. They were able to guarantee their surplus for the use of American troops and thus ensure an earlier and more numerous American participation upon the firing line. American divisions were therefore assembled rapidly, even though they were ahead of the munitions programme. The war came to an end before many of the elements in this programme of procurement were expected to be ready in sufficient supply. Many items would have continued to be procured abroad regardless of the length of the war, for the double purpose of saving ocean tonnage and giving profitable occupation to Allied civilian workers. Some items were delayed by faulty estimates or mistakes at home.

*Procurement in Time of Peace.*—The pre-war agencies for the procurement of munitions in the United States were shaped by the needs of small and permanent armed forces. In the Navy Department there was an old-established system of bureaux in which the needs were estimated and the supplies procured so smoothly that the only requirement of war was to enlarge the personnel of existing offices. In the War Department there was no central system of purchases; in the lack of one, each bureau bought independently for itself, the most important of the purchasers being the quartermaster-general, the chief signal officer, the surgeon-general, the chief of ordnance and the chief of engineers. Each of these departments had its own system of specifications and rules of purchase. Moreover, the

revolution in land warfare since 1914 had introduced new weapons of elaborate mechanism for which no department had any established precedents. When war began and efforts were made to expand the army in every direction the various procurement agencies developed duplication of work and inconsistency in standard, and by their competitive entry into the markets increased the scarcity of goods and raised the price.

*Military Organization.*—The inadequacy of the American military organization was recognized by the War Department as well as by critical observers on the outside, and after the outbreak of the World War numerous efforts were made to induce Congress to provide more completely for national defence. The reluctance of the people to assume military burdens in time of peace and the desire of the national administration to refrain from active war preparations while pressing its policies of neutrality retarded the movement for preparedness. In the winter of 1915–6 there was begun a serious attempt to correct deficiencies of the existing system, with the result that Acts of 1916 changed the basis of army, navy and civic coöperation for war. The National Defense Act (June 3 1916) and the Naval Appropriation Act (Aug. 29 1916) were in harmony with earlier American policies. The former left the army to be raised after entry into war, though providing in its officers' training camps a better means for training line officers than had prevailed in earlier wars, while the latter contemplated an effective navy. A naval building programme, covering a three-year period, was undertaken in the latter Act. It called for ten dreadnought battleships and six battle-cruisers; but it was not possible even to begin the construction of most of these until after 1918, and they had no effect upon the outcome of the World War.

*Council of National Defense.*—A Council of National Defense was provided for in an Act of Aug. 29 1916, constituting a new venture for the United States, based directly upon the experience of the European belligerents with the need to organize the whole of their social and industrial strength for the prosecution of the war. In no earlier war had the national effort involved so nearly the whole national strength as in this. The forces in the field were no more completely fighting the enemy than were the merchant marine, the manufacturers of war munitions, the producing farmers, and the civic agencies that saw to the rationing of national resources and their conservation. The Council of National Defense consisted of six members of the President's Cabinet, the Secretaries of War (chairman), Navy, Interior, Agriculture, Commerce, and Labour. It was not intended that these ministers, already burdened with the duties of executive departments, should personally undertake the task of mobilization of civic forces for war, but they were authorized to create an Advisory Commission of specialists in various fields of industrial activity who should direct the studies and coördination. As finally organized, the Advisory Commission of the Council of National Defense consisted of Daniel Willard, railway president and chairman; Bernard M. Baruch, an expert in raw materials; Howard E. Coffin, a manufacturer of motor-cars; Hollis Godfrey, an educator; Samuel Gompers, a veteran labour leader; Franklin H. Martin, an eminent physician; and Julius Rosenwald, a prominent merchant. Walter S. Gifford, an engineer, was selected as director of the Advisory Commission, and each member was made chairman of a committee according to his specialty.

The Council of National Defense did no important work until after the breach with Germany (Feb. 3 1917); between this date and the actual outbreak of war it sat in continuous session upon the problems of the procurement agencies of the Government, and more particularly those of the army, since the needs of the navy were less in amount and simpler in scope. Its special committees brought to Washington the men acquainted with the industrial resources of the United States and the available capacity for the manufacture of war material. There had been a voluntary survey of these resources conducted by a committee of the Naval Consulting Board, which the Navy Department organized in Oct. 1915. In the committee on supplies, of which Julius Rosenwald was chairman, numerous sub-committees were created at once to sit with officers of the Quartermaster's Department of the army in the scrutiny and award of contracts.

*Munitions Types.*—A large part of the munitions needed for maintaining an army of 4,000,000 men could be produced in the United States without difficulty because the articles needed were similar to those called for in time of peace. Such articles as shoes, socks, uniforms, blankets, food and food containers, camp utensils and equipage required only the drafting of specifications and the speeding-up of industry to produce the requisite amounts.

CLOTHING, ETC., PRODUCED AND SHIPPED TO THE A.E.F. BETWEEN APRIL 6 1917 AND NOV. 11 1918

| | Produced | Shipped |
|---|---|---|
| Blankets | 19,419,000 | 3,127,000 |
| Coats | 22,603,000 | 7,294,000 |
| Drawers | 71,884,000 | 14,701,000 |
| Undershirts | 69,764,000 | 13,693,000 |
| Shirts | 22,198,000 | 6,401,000 |
| Stockings | 89,871,000 | 29,733,000 |
| Shoes | 26,423,000 | 9,136,000 |
| Breeches and trousers | 17,342,000 | 6,191,000 |
| Overcoats | 7,748,000 | 1,780,000 |

Up to the point at which they called for more than the visible supply of raw materials they presented few problems different from those of ordinary manufacture. More difficult than these were the heavy manufactures of the material needed in transportation, beginning with ships, locomotives, and rolling-stock, and including the goods to be utilized by the engineers in France and by the construction division around the cantonments and factory towns. The Engineer Corps alone handled 3,225,121 tons of supplies during the 19 months of war; 1,303 locomotives and 18,313 freight cars were shipped to France; 1,002 m. of standard-gauge railroad track were constructed there. The manufacture of these goods was difficult, not because of their novelty but because it was often impossible to assemble rapidly the machinery with which to make them, and to build the new plants in which to construct them. In a war lasting only 19 months many of the preliminary processes could not be completed, nor quantity production be reached. Most difficult of all was the problem of manufacture of delicate or heavy ordnance, siege guns, field artillery, machine-guns, rifles, aircraft, tanks and motor transport, in which quantity production depended upon slow and painstaking preparation of the preliminary processes, upon the supply of labour and raw materials, and upon the wise selection of designs and types to be manufactured.

Considerable experience in the manufacture of ordnance and other munitions had been gained by private firms during the period of American neutrality through the fulfilment of contracts placed in the United States by the Allied belligerents. In April 1917 every shipyard had its ways filled with vessels on foreign order. Most of the private capacity to make explosives, rifles, machine-guns and cannon was similarly in use. The experience thus gained was an asset for the United States, but its value was limited by the fact that few of these resources could be diverted to the supply of American armies without endangering the supply of Allied armies already on the firing-line in the common cause.

*General Munitions Board.*—The evolution of the American equivalent of a munitions ministry begins in Howard E. Coffin's committee of the Advisory Commission of the Council of National Defense. Here it was early learned that new factories must be erected for the construction of guns, aircraft, and other munitions of the elaborate type, and that a preliminary determination of standards must precede this in order that the types put into production should be as few in number and as useful as possible. On March 29 1917, the Munitions Standards Board came into existence to advance this work as a sub-committee of the Council of National Defense. Frank A. Scott, a Cleveland engineer, was chairman of this board, and directed its study of requirements with a view to standardization. Within a few days it was learned that the Board must do either more, or nothing, since unless it could get preliminary statements of the needs of the army and navy its work was fruitless. On April 9 it was reorganized as the General Munitions Board, because

said Gifford, the director of the Advisory Commission, "it was necessary, if we were going to give intelligent advice, that somehow we should have a system for clearing the needs of the army and navy, and for having the needs brought before the people." The General Munitions Board included, at first, seven military and eight naval officers, and Baruch, Coffin, Martin and Rosenwald from the Advisory Commission. Its purpose was to coördinate army and navy purchases, to establish precedence of orders between the two departments and the industrial needs of the country, and to determine priority of delivery of materials. It was dependent for its success upon its powers of persuasion. The Secretary of War directed his supply departments to declare their needs to the General Munitions Board when time permitted, but reminded them that the full responsibility of the supply departments remained unchanged.

Within a few weeks of the declaration of war numerous special bodies were created to carry on parts of the munitions work. A Railroads' War Board (April 11) undertook voluntary direction of the operation of railway lines, retaining it until the inauguration of the Railroad Administration (Dec. 26) under Director-General W. G. McAdoo. The Emergency Fleet Corporation (April 16) was created as a construction agency of the U.S. Shipping Board, with Maj.-Gen. George W. Goethals in charge, succeeded in turn by Rear-Adml. W. L. Capps and Charles M. Schwab. The Aircraft Production Board (May 16) under Howard E. Coffin exercised indefinite powers, in conjunction with the Signal Corps of the army, over the designing and execution of the aeroplane programme. It undertook, said the Chief of Staff, in 1919, "an air programme entirely disproportionate to a properly balanced army and, as events showed, impossible of execution . . . practically independently of the rest of the army." Behind all these, the Council of National Defense stood in an advisory capacity, making suggestions, appointing other sub-committees, bringing citizens into contact with the Government bodies, but not generally administering the war agencies except in their initial steps.

The various parts of the munitions programme developed in accordance with estimates as to the number of men that could be put into the line in France. In the spring of 1917 it was hoped to have 1,000,000 men there by the end of 1918; but the Allied commanders did not believe that American troops could be of use for independent work even by that date. This programme was frequently revised, until in July 1918 the Chief of Staff recommended preparations to put 3,360,000 American troops in France before July 1 1919. The responsible departments, the special war bodies, and many civic agencies worked with abundant patriotic goodwill, and confusion was perhaps inevitable because of the undefined functions of the new war machines. Among the thousand of items to be procured, those that involved the country in the most uncertainty and controversy were ships, aircraft, gas and appliances for using it, heavy ordnance, artillery, rifles, and machine-guns.

*Ships.*—When the Emergency Fleet Corporation began work there were 256 shipways in the United States capable of constructing ships of 3,000 deadweight tons[1] capacity, distributed among 87 yards mostly along the Atlantic coast. The merchant tonnage of the United States was 3,569,675 gross tons.[1] An early phase of the shipbuilding work was the designing of standard wooden ships of 3,000–5,000 tons and steel ships of 5,000–8,000 tons. Contracts were placed, before the Armistice, for building 17,399,961 deadweight tons, of which 2,368 new vessels, aggregating 13,616,836 deadweight tons, were retained in the final reduced programme of June 30 1919. By this latter date 1,056 ships of 5,858,164 deadweight tons had been delivered, many of them from new yards or new ways erected in old yards. By the date of the Armistice the merchant tonnage had been increased, in excess of marine losses and enemy destruction, by 498 ships of 1,944,773 gross tons, without counting enemy ships seized or Dutch ships requisitioned.

[1] It was the practice of the Shipping Board to compute new tonnage in deadweight tons, representing the actual freight-carrying capacity of the vessel, instead of gross tons, which are derived arbitrarily by dividing the external cubic dimensions by 100 cubic feet. The ratio between deadweight and gross tons varies with the type of vessel; rough formula for conversion is, 1 gross ton equals 1.60 deadweight tons.

The question of building the emergency ships of wood or steel aroused warm controversy between those who saw in the wooden ship a means of putting to use materials and labour that were relatively plentiful, and those who believed that only the steel ship could perform the work required. Contracts for steel ships of standardized design were let in large numbers to existing companies, or to new companies organized to receive contracts. In addition to these, provision was made for making separate parts of ships in numerous inland factories and assembling them in great Government yards, at Hog Island, on the Delaware river below Philadelphia, with 50 erecting ways; at Newark, N.J., with 28; and at Bristol, Pa., with 12. The contract for building the Hog Island yard, in an unimproved but accessible swamp, was signed Sept. 13 1917; the first ship assembled there, the "Quistconck," was launched Aug. 5 1918; a keel was laid on the fiftieth way in Nov. 1918; but in spite of all the speed that patriotic effort and lavish expenditure could produce, not one of the fabricated ships took on a cargo before the Armistice. The results of the ship-building programme could not have been realized before 1919. In addition to the increase of the merchant tonnage through the building of new ships upon contract of the Emergency Fleet Corporation, the Government requisitioned all American ocean-going vessels, seized enemy ships in American ports, chartered many neutral ships, and requisitioned Dutch ships lying idle in American waters and partly finished vessels that were under construction for foreign owners. The growth of shipping under the American flag (in vessels of 500 gross tons or over) is as follows:—

| | Ships | Gross tons |
|---|---|---|
| Strength April 6 1917 | 1,614 | 3,569,675 |
| New construction to Nov. 11 1918 | 704 | 2,287,034 |
| Ships otherwise acquired to Nov. 11 1918 | 95 | 274,366 |
| Enemy ships seized in United States | 97 | 648,894 |
| Dutch ships requisitioned | 87 | 354,278 |
| Total to Nov. 11 1918 | 2,597 | 7,134,347 |
| Ships lost April 6 1917–Nov. 11 1918 | | |
| By enemy action | 103 | 313,569 |
| By other causes | 213 | 416,578 |
| Strength Nov. 11 1918 | 2,281 | 5,404,200 |

*Aircraft.*—Prior to April 6 1917, the United States had acquired in all 224 aeroplanes, which were controlled by the Signal Corps of the army, and none of which reflected in their design the lessons of the World War. The appropriations of Congress for military aviation are as follows:—

| | |
|---|---|
| 1912–6 | $900,000 |
| 1916–7 (Urg. Def. Bill) | 500,000 |
| 1917 (Army approp.) | 13,281,666 |
| 1917 (Milit. aeronautics) | 16,800,000 |
| July 24 1917 | 640,000,000 |
| 1917–8 (Urg. Def. Bill) | 43,450,000 |

The funds thus made available were expended first by the Signal Corps in conjunction with the Aircraft Production Board and the Aircraft Board which superseded it Oct. 1 1917; then by the Bureau of Aircraft Production of the War Department which was created May 20 1918 under John D. Ryan; and after Aug. 28 1918 by the Air Service of the War Department with the same director. The policy was to design a standard type of aeroplane engine, put it into quantity production, and have ready for the campaign of 1918 a fleet of 22,000 effective aeroplanes. By July 4 1917 the first experimental "Liberty Motor," as the standard engine was named, had been constructed. After further refinement of design it was turned over for production to the manufacturers of automobiles in the absence of large aircraft industries in the United States. The first finished Liberty engines were delivered in Dec. 1917, and 15,572 more followed within the next year. The first American squadron, completely equipped by American production, was reported by Gen. Pershing to have crossed the German lines on Aug. 7 1918. The A.E.F. was provided by the French Government with 2,676 aeroplanes, and received from the United States 1,379 planes of the De Haviland type. The delivery of aeroplane engines of all types to the Government in the United States began with 66 in July 1917, and rose to 5,297 in Oct. 1918, with a total of 28,509 to the end of Oct. 1918.

*Toxic Gases.*—Much of the preliminary work in gas warfare was done in the U.S. Bureau of Mines, which had already made studies in connexion with the safety factor in the operation of mines. The laboratories of leading universities took up experiments before the declaration of war, and there was gathered at the American University in Washington, D.C., a nucleus of experts in the investigation of problems in gas offence, gas defence, toxicology of gases, and the manufacture of gas and containers. The strictly military study of the use of toxic gases was made in the French Warfare Section of the Ordnance Department, but it was necessary to call into the work the officers of the Medical Department. There was no commercial equipment in America for gas manufacture upon the scale needed for the American programme, and the Edgewood Arsenal (1,100 acres) in Maryland was accordingly built to manufacture gas and fill gas shells. In June 1918 the various agencies concerned in gas warfare

were consolidated by the President, under authority conferred upon him by the Overman Act, and became the Chemical Warfare Service of the army. Additional projects were developed to keep pace with experience in Europe, the programme of American production rising from 345 tons per week (March 1918) to 4,525 tons per week (Aug. 1918). German production of mustard gas, at the date of the Armistice, was believed to be not over 50 tons per week.

The manufacture of gas progressed so rapidly as to get far ahead of the manufacture of empty shells; and these were far ahead of the boosters needed to explode them and scatter the charge. Toxic materials, to the amount of 4,278 tons, were shipped in bulk to Europe to be there loaded into shells, and provided the full equivalent of the gas used in all the gas shells fired by the A.E.F. No American gas was fired in American shells.

GAS MANUFACTURE AND SHIPMENT

| 1918 | Toxic materials produced (in tons) | Grenades, shell, etc., filled | Toxic materials shipped overseas (in tons) | Shell, etc., shipped overseas |

| Total | 10,817 | 1,414,069 | 4,278 | 868,664 |

*Heavy Ordnance.*—There were 97 officers at work in the Ordnance Department at the time America entered the World War, only 10 of whom were experienced in designing artillery weapons. While expanding this commissioned force to 11,000 during the 19 months of war, it was necessary also to design and direct the production of the ordnance for an army of 5,000,000 men. Only six Government arsenals and two private plants had had experience in producing heavy ordnance before 1914; the number was increased by "a score or so" by 1917, because of Allied contracts for artillery, ammunition, rifles, machine-guns, etc.; by Nov. 1918 there were nearly 8,000 plants at work upon ordnance contracts, light or heavy.

The heavy-gun capacity of American makers was all under Allied contract in April 1917, with a year's work ahead. Up to the Armistice 1,102 guns (from 3 in. to 9·5 in.) and 14,623 forgings (from which the finished guns are turned and bored) were thus made in the United States for the Allies. Fifteen additional heavy-gun factories were equipped to meet the American need, and all but three (whose machine tools were delayed) were producing forgings before the Armistice; the rate for Oct. 1918 was above 24,000 guns per year.

In mobile field artillery the French 75-mm. gun was accepted for the standard in quantity production, and its designs, with those for its intricate recuperator, were redrawn to meet American conditions in manufacture. The tolerances, which the French were in the habit of working out in the assembling plant, were reduced to figures and gauges in order to permit the American method of manufacture of separate, interchangeable parts. In Oct. 1918, 464 complete artillery units (guns, carriages and recuperators) were produced and delivered to the army by American manufacturers, with an accumulated total of 2,058 units to the end of the year. But no 75-mm. guns or 155-mm. howitzers of American manufacture were on the front at the date of the Armistice. The French Government provided the A.E.F. with equipment of this sort sufficient for 30 American divisions.

*Rifles.*—The rifle selected for use in the A.E.F. was the 1917 Enfield, a model adapted from the British rifle which had been developed in quantity production in American factories, upon British orders, 1914–7. It was selected, not because it was believed to be superior to the 1903 Springfield (the standard then in use in the American army), but because the Springfields could be made only in the Government arsenals at Springfield, Mass., and at Rock Island, whose capacity had been determined by Congressional action and could not be expanded as rapidly as the emergency required. The factories built for the manufacture of Enfields, on the other hand, had completed their foreign orders and stood available for immediate American use. The decision of the War Department was to adapt the Enfield to shoot the standard rimless .30 calibre Springfield cartridge, to complete the standardization of the Enfield, and to produce it in these private plants. There was no shortage of American-made rifles for overseas use. For the purpose of training, until quantity production should begin, the American troops relied upon the pre-war stock of about 600,000 1903 Springfields and 300,000 of the older Mauser rifles which the Springfield had displaced. The arsenals were kept at work on the 1903 Springfields, raising their production to 2,500 rifles per day at the Armistice. The statistics of rifle production[1] are:—

| | 1903 Springfield | 1917 Enfield |
|---|---|---|
| 1917 | 128,475 | 302,887 |
| 1918 Jan. | 31,570 | 153,499 |
| Feb. | 9,370 | 170,857 |
| March | 540 | 160,142 |
| April | 2,631 | 167,485 |
| May | 3,970 | 181,034 |
| June | 6,759 | 191,354 |
| July | 16,879 | 231,193 |
| Aug. | 28,617 | 191,769 |
| Sept. | 33,583 | 199,635 |
| Oct. | 39,176 | 187,477 |
| Nov. (1–9) | 11,308 | 56,097 |
| Total | 312,878 | 2,506,307 |

*Machine-Guns.*—A large appropriation ($12,000,000) for the purchase of machine-guns was made in the Army Act of Aug. 29 1916, and 4,000 Vickers guns (heavy) were ordered shortly thereafter, but the War Deparment had not completed its test of types or made its selection of a light machine-gun on April 6 1917. Before the World War the machine-gun did not play a large part in military equipment, and there were not in existence either patterns of completely satisfactory type, or facilities for wholesale manufacture. An American gun, invented by Col. I. N. Lewis, "was a revelation when it came to the aid of the Allies early in the great war," and capacity for its manufacture was developed in private American plants on Allied order. This, and other types, the Vickers, Benêt-Mercié, Maxim, and Colt, were under experiment by the Machine-Gun Board when America entered the war. The board continued its deliberations until satisfied. Since the whole capacity of the Lewis-gun factories was contracted for, it was certain to be several months before this or any other gun could be produced on a greatly increased scale. In May 1917, the Machine-Gun Board tested and adopted two newly designed guns, one heavy and one light, both the work of John M. Browning. The first light Brownings were accepted in Feb. 1918; the first heavy Brownings in the following April. Thereafter the new industry gained rapidly in volume, until during Oct. 1918 the War Department accepted 14,639 heavy and 13,687 light Browning guns. By the end of the year 226,557 machine-guns of all types had been accepted by the United States. The production of the Lewis gun was continued, it becoming the standard gun for aircraft. At the Armistice there were enough heavy Brownings in France to equip all American divisions there, but there had not been opportunity to issue them generally to the troops in exchange for the various other guns in use.

*Naval Ordnance.*—Naval ordnance presented fewer difficult problems than that for the army because the quantities needed were less staggering, and fewer weapons represented novelties in manufacture. The construction of battleships was practically stopped during the war, the whole strength of the navy yards being concentrated on smaller vessels, with destroyers and submarine chasers at the head of the list. The manufacture of the latter led to an experiment with quantity production of a fabricated steel chaser, the "Eagle" type, at a new Ford plant near Detroit.

Much delicate experimentation was done in search for new range-finders and submarine detectors, various listening devices being brought forward for the latter purpose. The construction of the North Sea mine barrage called for the development of a new mine and anchor and tested the ingenuity and capacity of manufacturers working in a new field. The formal approval by President Wilson of the plan to lay a barrage of anchored contact mines from the Orkney Is. to the Norwegian territorial waters off Udsire Light, a distance of 230 m., was given on Oct. 29 1917, after the British Admiralty had assented to the joint project. The Bureau of Naval Ordnance was already at work upon the mechanism, in advance of approval, and was able to summon the manufacturers to a conference early in November. Contracts for making the various parts were placed with a large number of plants, and the first mines were ready to test by March 1918. Orders were placed for 125,000 mines, of which 56,611 were laid in the barrage by American mine-layers operating from bases in the N. of Scotland, near Inverness. The whole barrage included 70,263 mines, of which 13,652 were British laid, covering a zone of sea from 15 to 35 m. in width, and to a depth sufficient to prevent submarines from diving under it. The complete barrier was in place by July 29 1918, although it was much tightened thereafter. The barrage is known to have destroyed 17 submarines and to have closed the North Sea outlet, particularly after Norway announced a determination to mine her own territorial waters adjacent to the barrage. (*Navy Ordnance Activities, World War*, 1917–1918, p. 125.)

*Evolution of the War Government.*—The evolution of the munitions programme, as the proportions of the American effort were extended, was simultaneous with the execution of its details. An attempt to give it unity and proportion was made from the start under disadvantages due to the newness of the ad-

[1] *America's Munitions*, p. 186.

ministrative organizations and the uncertainties or difficulty of the work itself. Before the execution of the programme was far advanced further necessity for coördination was seen, as experience developed shortages in capital, labour, raw materials and transportation, and as it came to be recognized that the whole programme would stand or fall upon the proper adjustment of priorities among war and civilian needs. The disrupting haste due to the imminence of invasion was never present, but the object was to make the American addition to the Allied force sufficient in volume to crush the enemy armies.

The General Munitions Board and the various committees on special commodities erected by the Council of National Defense proved themselves less than adequate before midsummer, 1917. A common ground for complaint was the fact that many of the committee-men were loaned to the Government by firms that were bidding for contracts, thus placing the committee-men in the embarrassing position of awarding contracts to themselves. Disappointed bidders complained that there was favouritism in the granting of awards. More than this, the powers of the General Munitions Board were too small to enable it to have the full knowledge essential to a scheme of priorities.

*Purchasing Commission for the Allies.*—Among the difficulties was the presence in the American market of buyers for all the Allies, spending funds loaned by the United States (under Act of April 24 1917), and bidding both against themselves and against the American army and navy. Allotments of the available supply of raw material were made, not according to needs but upon a competitive basis that produced uneven distribution and rising prices. In Aug. 1917 an agreement was reached with the Allies whereby their buying in the United States was concentrated in a Purchasing Commission, (Bernard M. Baruch, Robert S. Brookings, and Robert S. Lovett), and discussions were started that led eventually to the creation of the Inter-Allied Council on War Purchases and Finance, which began work in London, Dec. 1917. Meanwhile the General Munitions Board had been reorganized upon a broader scale.

*War Industries Board.*—As early as July 1917 President Wilson served notice that price-fixing powers would be needed by the Government, and Congress conferred the necessary authority upon him by Act of Aug. 10 1917. On July 28 the War Industries Board superseded the General Munitions Board, under Frank A. Scott, head of the defunct organization. In addition to the chairman, the War Industries Board included men active on the Council of National Defense, and the whole personnel of the Purchasing Commission for the Allies. Baruch specially represented raw materials, Brookings was in charge of prices, Lovett concerned himself with priorities, Hugh Frayne represented labour, and there were additional representatives from army and navy. A great change in the civilian conduct of the war followed this reorganization. In Nov. Scott, who retired because of bad health, was succeeded by Daniel Willard, chairman of the Advisory Commission of the Council of National Defense; and Willard was in turn succeeded in March by Baruch. The terms of Baruch's authority were conveyed in a letter of March 4 1918 in which President Wilson directed him to make the War Industries Board the agent of the Government in all matters of supply. Between March and Nov. 1918 the War Industries Board became a sort of munitions ministry. It continued a part of the Council of National Defense until after the passage of the Overman Act, May 20 1918. This Act was demanded by the President in Feb., at a time when his critics were calling for a minister of munitions. He insisted that the full control of the war must be left in the hands of the executive, but urged that he be given power, for the good of the cause and the duration of the war, to make rearrangements in existing bureaus, to re-group or create new bureaus, and to transfer appropriations from one agent of Government to another as needed. The War Industries Board was instantly cut loose from the Council of National Defense upon passage of the Act; the Chemical Warfare Service was launched as an independent agency, and the aviation functions of the Signal Corps were transferred to new bureaus of Aircraft Production and Military Aviation, and later to the Air Service.

The chief divisions of the War Industries Board revolved around the Requirements Division, to which representatives of army, navy, emergency fleet, railway administration and Allies reported their programmes of requirement. In order to solve problems of priority in delivery, the board created a great series of Commodity Sections, under the direction of civilian experts who were required to disinvest themselves from business, and these Commodity Sections encouraged the creation of War Service Committees by the manufacturers in every line of industry. More than five hundred such committees were finally organized, and brought their testimony as to the capacity of their industries to the Commodity Sections, and these to the Priorities Division of the Board. After the several requirements were cleared by the Clearance Division, upon order of the Requirements Division, the Price-Fixing Committee was brought into action, in cases where it was necessary to hold prices down or to raise them enough to stimulate the needed production. This committee, though interlocked with the War Industries Board, was not a part of it but was a separate creation by the President. The work of determining cost of production, as an element in the fixing of prices, was done for the Price-Fixing Committee by the statisticians of the Federal Trade Commission. A Conservation Commission was created to consult with Commodity Sections and War Service Committees upon the proper distribution of the raw materials remaining for civilian use after the military needs were met. A War Finance Corporation (April 5 1918) was created by Congress and authorized to advance funds to banks to cover loans made by them to munitions makers, in order that these might convert their factories or expand them in the public service. A Resources and Conversion Division made surveys of industries that could be converted to war use; a Facilities Division studied the possibilities of creating new establishments for the same purpose. Before the end of the war new construction for non-war use was stopped except in case of minor repairs, and Capital Issues Committees, attached to the Federal Reserve banking system, received authority to pass upon and veto private applications for loans of capital for non-war use. Other sections or divisions were added to complete the war organization of industry under the general supervision of the War Industries Board. (*Handbook of Economic Agencies of the War of 1917*, prepared in the Historical Branch, War Plans Division, General Staff, 1919.)

*Other War Boards.*—Except in the army and navy, the great agencies of procurement grew up outside the permanent departments of Government. The Shipping Board was the first of the new war boards to begin to function. It was followed by the Food Administration (Aug. 10 1917), under the direction of Herbert Hoover, who had conducted a voluntary Food Administration after May 19, while Congress was debating the projected Food and Fuel Control Act. On Aug. 23 1917, Harry A. Garfield became head of the Fuel Administration. The War Industries Board (July 28) was by no means as pervasive as it became in 1918, but was active from its creation. Under the Trading with the Enemy Act (Oct. 6 1917) the President created on Oct. 12 the War Trade Board, with Vance McCormick as chairman. The function of this body was to supervise imports and exports for the purpose of conserving tonnage, securing the necessary raw materials for the munitions programme, and preventing the enemy from deriving any advantage out of American foreign commerce. The Alien Property Custodian (Oct. 6 1917) transferred alien enemy property into the hands of a trust administrator to prevent the enemy from deriving advantage from American industry. The Railroad Administration (Dec. 26 1917) was the last of the great war boards to be created. During the spring and summer of 1918 the President held frequent conferences with the heads of the six great boards and the Secretaries of War and Navy, this body being spoken of informally as the "War Cabinet."

*Centralization in the War Department.*—The Navy Department made few changes in its basic organization during the war, but the War Department was in continuous readjustment. The several independent buying agencies were rearranged by functions, so that given commodities might be procured for the whole army by a single purchaser, and all military finance pass under a single eye. In Dec. 1917 Maj.-Gen. George W. Goethals was taken into the War Department as Director of Storage and Traffic of the General Staff. The General Staff did not find its wartime chief until Gen. Peyton C. March took charge (March 4 1918), being sent back for that duty from the A.E.F., his immediate predecessor as chief of staff was Gen. Tasker H. Bliss, who remained in France at the Supreme War Council. He was preceded by Maj.-Gen. Hugh L. Scott, who was in office at the

outbreak of the war, and accompanied the American mission to Russia in 1917.

Goethals reorganized all the procurement agencies of the War Department, taking many of them away from the former bureaus and building up a new organization under himself. In Jan. 1918 Brig.-Gen. Palmer E. Pierce was made Director of Purchase and Supply, while Edward L. Stettinius, a banker who had acted as buyer in America for the Allies, was made Assistant Secretary of War to coöperate with him. In April the Purchase, Storage, and Traffic Division of the General Staff took over the functions of both of these divisions, and, as "P., S. and T.," under Goethals became the most visible of the War Department agencies at the national capital. Stettinius was sent abroad to the Inter-Allied Munitions Council, and Benedict Crowell became Assistant Secretary of War and Director of Munitions. (Crowell, *America's Munitions, 1917-1918*, Washington 1919.)

The reorganization of the War Department, the expansion of the Navy Department, the creation of the War Boards, and the rise of the War Industries Board as the coördinating agency were simultaneous processes. The condensation of so much activity in a few months makes it difficult to award praise or blame to individual organizations; but at the date of the Armistice the new War Government was functioning, having converted the United States to the single purpose of winning the war.

*Labour.*—The six great war boards included all the fundamental elements except labour. By the adoption of the Selective Service Act (May 18 1917), the policy was established of permitting only those to serve with the colours who could be spared from the tasks of production, and before the end of the year the draft registrants were classified according to their industrial importance. Labour was brought into coöperation with the scheme of procurement through the various committees organized by Samuel Gompers for the Advisory Commission, and the Government agreed that, in consideration of an attempt on the part of Labour to keep the work moving, the United States would endeavour to preserve the standards and health of Labour as against the dangers of rising wages, labour scarcity and uneven housing conditions. In each of the larger war agencies some sort of Labor Bureau or adjustment commission was created, and Congress acted upon the initiative of a committee of the Council of National Defense by making appropriations for housing facilities in congested regions, which were administered in part by the U.S. Housing Corporation, and in part by the Shipping Board. Early in 1918 the Department of Labor created a commission of employers and labour to draw up a formal programme for labour treatment. As a result of the report of this body the President created (April 8 1918) the National War Labor Board, presided over by ex-President William H. Taft and Frank P. Walsh, to act as a supreme court for the adjustment of labour disputes. This was followed (May 13 1918) by the appointment of a National War Labor Policies Board, upon which all the producing agencies were represented, whose function was to determine standard policies and eliminate inequalities prevailing in the practices of the numerous production agencies. Within the Department of Labor various labour services were inaugurated or expanded, notably the Children's Bureau, the Woman in Industry Service, and the Employment Service. On Aug. 1 1918, by executive order, the Employment Service took over through its own offices the whole task of placing unskilled labour in American industry in order that labour priority orders might be respected and that the employees of one concern might be freed from "wage raids" made by other establishments. All private employment offices were closed, and labour was generally driven out of non-essential occupations by two orders: (1) a ruling of the Provost-Marshal-General denying deferred classification under the draft on grounds of dependency to men engaged in the occupations marked non-essential on his list (May 17); and (2) a classification of industries by the Priorities Division of the War Industries Board grouping industries in the order in which it was important and permitted that they be supplied with fuel, raw materials, transportation and labour (Sept. 3).

*Government-Owned Corporations.*—In the execution of the munitions programme a device relatively new to American practice was frequently used in the corporations whose capital stock was entirely owned by the Government of the United States. Government production was normally slow and expensive because of the red tape and lethargy inherent in civil service establishments. Financial operations were embedded in legal requirements adopted not to expedite work but to ensure honesty in expenditure. Private business, on the other hand, could make decisions and apply funds with the promptness desired of Government offices in time of war. The Shipping Board Act authorized the creation by the Shipping Board of a corporation all of whose stock should be subscribed by the board out of a fund appropriated by Congress. As stockholders the members of the board elected directors for the corporation (generally themselves); and the directors were at liberty to disregard Government red tape and to act as freely as any private directorate under the general laws of the state granting the charter. The Emergency Fleet Corporation was organized pursuant to this authorization, and the freedom of action thus obtained inspired other war boards to imitate the process. The U.S. Grain Corporation and the Sugar Equalization Board were created by the Food Administration to administer the work of stabilizing the price of flour, sugar and coffee. The Spruce Production Corporation was jointly owned by army and navy aircraft interests and the Allies, who were thus required to pay their share of the overhead charge in producing spruce lumber for aeroplanes. The War Finance Corporation was a subsidiary of the Federal Reserve Board, doing a banking business in buying war-loan paper from individual banks. The War Trade Board Russian Bureau was organized in the closing days of the war when it appeared that Government stimulation of trade with Siberia would be useful. The U.S. Housing Corporation was an operating subsidiary of the Department of Labor. (F. L. P.)

### III. The Central Powers

No department of army supply gives so clear and comprehensive a picture of the whole war administration of the Central Powers as that of the munitions supply. The error of the peace-time preparations lay in the under-estimation of the length of the war and of the fighting needs, and in the inadequate provision for the mobilization of industry. With this naturally went deficient arangements for building up reserves of raw material. The difficulties were the greater, since, owing to the effects of the blockade, the supply of food for the army and for the civil population were largely parts of one and the same industrial problem, owing to the many points of contact between the respective demands. Quite apart from the question of coal—and taking, for instance, fats, sugar, and alcohol, all needed in the manufacture of explosives—in Austria-Hungary 50,000 tons of sugar had to be withdrawn for that purpose from the food supply in a single year, while in Germany during a like period 900,000 tons of potatoes were used in the production of alcohol for explosives. Military supplies of many other kinds were also greatly affected by the demands of the Munitions Department. Almost the whole of the national economic life had to be adapted to this particular necessity, and in this respect the situation was truly that of a beleaguered fortress. The home industries had to be specially developed in order to meet the pressing need; and it was here especially that Germany took the lead among her allies. Because of her superior strength she had to be responsible for such of their supplies as their own means were inadequate to provide. This amounted to practically the whole in the case of Turkey and Bulgaria. A consideration, either of the war economy as a whole or of the supply of munitions alone, may therefore be properly confined to the performance of the two great Central Powers.

At the beginning of the war, and even more in its earlier months, Austria-Hungary depended upon Germany's mightier and more complex production for various kinds of war material, and especially for certain important raw materials. The Danube monarchy was far from being so homogeneously organized as either Germany or France. In contrast to the highly developed and qualitatively important industries of Lower Austria, parts of Steiermark, Bohemia, Moravia, and a few small Hungarian centres, there were vast areas which were entirely impotent in an industrial sense. The form of the political system also prevented complete central control of the whole available strength of land and people. Regions of advanced culture existed side by side with immense tracts which were hardly at all developed. Austria-Hungary was always greatly inferior to Germany in the matter of raw materials. Her sole advantage lay in the naphtha wells of Galicia; and this ceased to exist soon after the beginning of the war, when the Russians invaded that region. The scarcity of coal was always a great difficulty; even in peace-time she was dependent on Germany for supplies. The Austro-Hungarian Empire possessed an iron and steel industry of the first rank as regards quality. Quantitatively, it could not compete with the German industry, chiefly owing to the above-mentioned lack of coal, but qualitatively the product was not only not inferior to that of Germany, but it ranked next to the English high-grade steels in the world-markets. The magnificent armament industry was second only to this well-

developed high-grade steel industry. What Krupp and Ehrhardt were to Germany, the Skoda works and the firm of Böhler were to Austria-Hungary, and eventually the Hungarian gun factory at Györ, which was under the management of Skoda, was added to these. For small arms and rifles Austria-Hungary possessed, in the front rank, the Steyr armament works. All these private sources of production in conjunction with the State factories which, since the time of Uchatius, had been capable of a large output, were soon in a condition to undertake the entire supply of the Austro-Hungarian army, and also to share in the equipment of her weaker allies with guns, small arms and shells.

The chemical industry was, however, totally inadequate, so that in this respect the Danube monarchy was very largely dependent upon Germany, and consequently had difficulty in producing the necessary explosives in sufficient quantity. In fact, the inadequacy of the powder and explosive production of Austria-Hungary made itself felt all through the war, and was the main cause of the crises which occurred from time to time in the munitions supply. The truth is that neither of the Central Powers was at first equipped for coping with the unexpectedly great and urgent demand for munitions, any more than were the rest of the belligerents.

The difficulties created in Germany by the blockade were increased by Austria-Hungary's lack of raw materials, which rendered her almost powerless to offer any compensation for the loss of overseas imports. Only after Gorlice (May 1915) did her petroleum industry begin to contribute to the common war economy, and besides this, strictly speaking, only her bauxite deposits, magnesium works and timber stocks were worthy of mention beside Germany's extensive contribution.

Nevertheless, Germany succeeded in carrying on the war, which was so largely one of materials, for 4½ years, and Austria-Hungary's contribution of material (for example, of guns and ammunition) was for a long time in the proportion of 1:3 to that of Germany. These facts afford a proof of the remarkable way in which Germany adapted herself to the war necessities, and also of the height of her technical accomplishment; they are no less a sign of the immense vitality of the Dual Monarchy, which was contrary to all expectation even in Austria-Hungary itself. The achievement of the much weaker Austro-Hungarian industries is perhaps the greater marvel, for the difficulties of obtaining raw materials, of finding the necessary workmen, the transport problem, and, lastly, the very different degrees of development in the various regions weighed heavily indeed. Both the Central Powers achieved seeming impossibilities in utilizing the entire productive capacity of their populations, the more so as all active classes of the people were called up during the war, as in the other belligerent States.

The actual organization of production is dealt with later in this article. Before coming to it, we will describe generally the character of the problem to be faced in respect of the forms of munitions employed by the Central Powers.

*Artillery Ammunition.*—The two empires had always been entirely independent of one another as regards the development of the whole artillery, small arms, machine-gun, and ammunition production. Only in course of the war did an active interchange of field and factory experience take place. Bulgaria and Turkey, until the war, competed for their weapons in the open market.

The shell, as the shooting agent, is so entirely dependent structurally upon the shooting apparatus, that ammunition can only be dealt with in relation to the guns concerned. The ruling consideration in the manufacture of guns must likewise be their conformity with the possibilities of shell construction.

The Central Powers—like the French on their introduction of the 75-mm. field-gun, which was believed capable of satisfying all requirements—endeavoured to unify the artillery weapons of the field army as much as possible; that is, to make one type of gun suffice. However, opinion soon came round to the view—the correct one, as the war showed—that both the light and the medium field-artillery required a high-angle gun. In Austria, particularly, where the mountainous nature of the country had led before the war to the production of conspicuously good high-angle guns and notably mountain guns, the view was held that even the light artillery must have shells of great penetrating power for vertical fire against the covered-in shelters and stone defences to be looked for in mountain warfare. In both the Central Empires judgment went against the artillery experts who were in favour of greater mobility and lighter ammunition. However, both armies possessed a medium artillery (up to and including 15-cm.) which was highly effective as regards the individual round. At the beginning of the war Germany already had modern light and heavy howitzers, and also the 21-cm. mortar. It is true that the Austro-Hungarian medium artillery was only equipped with the new patterns after the first few months of the war, the tests being then barely completed; the existing types of howitzer were, however, not inferior, either in shooting effectiveness or in the matter of shells. While the Austro-Hungarian super-heavy howitzers were undoubtedly superior in mobility and effectiveness to that of all the other armies, the German medium and heavy flat-trajectory artillery were immensely superior.

The weapons referred to are the 30·5-cm. mortar (380-kgm. shell; 11 kilometres' range), and the 42-cm. howitzer (1,000-kgm. shell; 12 kilometres' range) of Austria-Hungary, already existing in peace time, to which the 38-cm. howitzer and the 21-cm. mortar were added during the war. All three were designed for motor traction. The German long-range gun is also included. At the beginning of the war Germany had also her 42-cm. howitzer, which, however, was inferior in mobility to the Austrian.

The different lines of development of the German and Austrian artillery were determined by the form of their respective main theatres of war. Austria-Hungary, which had to adapt its artillery to the destruction of the enemy forts distributed through all the important mountain passes and the rocky shelters to be found in the hills, clearly had to make her gun and ammunition construction correspond to this necessity. There was thus more urgent need for shells with solid points, and therefore base-fuzes.

Reviewing the technical triumphs of the World War, it is clear that in the domain of artillery ammunition there was no advance—gas ammunition excepted—on the pre-war principles of construction. This applies to all the belligerents. In spite of the efforts at uniformity, the munitions equipment necessarily became very varied during the war, because it had to conform to the varied character of the fighting, of the ground, and, lastly, of the production, which was subject to the supply of raw material and to the capacity of the factories. However, the new products were almost always constructed on the old lines, and all new types which resulted from lack of the customary material appear, when closely examined, as no more than forced solutions of a difficulty. The ammunition, like the gun material, remained unchanged in principle, only tending towards a gradual intensification, without any change in essential character. No new propellant, no new explosive, no new body or driving-band material, not even a really new and better fuze, emerged from this unparalleled trial of strength, this world-wide competition in technical ability. In two directions only may real improvement be noted: the false-cup shell which increased range and brought up fresh ballistic problems in connexion with the upper air, and the shell of the Austrian 30·5 motor-mortar, which was the first high-trajectory projectile combining armour-piercing effect with mine-effect. This latter shell was the product of the very developed native high-grade steel industry. With an explosive charge of 38 kilogrammes, it had (like the mine-shells of the field howitzers) a 10% efficiency (proportion of explosive to total weight), and yet, with an initial velocity of about 300 metres a second, was able to penetrate 250 millimetres of reinforced nickel-steel armour without deformation. This necessitated a resisting capacity, taking pressure alone, equal to 21,600 kilogrammes to the square centimetre, and it was not a thick naval shell, but a thin-walled mine-shell, of which the point and shoulders had to be hardened. The material was a specially reinforced alloy of high-grade steel. The results obtained with this in peace-time had already induced the German army chiefs to place orders with Austrian works for shells for their 21-cm. mortars.

*Developments in Manufacture.*—In the case of guns and of ammunition alike, the war-developments in manufacture were of an industrial nature in both the Central Empires. The military authorities exercised an influence over this development through the orders they placed and the experiments they caused to be made.

In Austria-Hungary there was a special Artillery Staff, the officers of which were recruited, like those of the General Staff, from the General Staff School, and received, in addition, a special technical training. For this reason, and also because it was in constant touch with the troops, this corps was able to judge, from both a military and a technical standpoint, what demands should and could be made for any kind of military material. The ammunition—with the exception of special types, as, for example, the Ehrhardt "Universal" shell—was actually designed in the military bureaux of this staff. Hence the Austrian ammunition was from the beginning more uniform in construction, and the work done by the staff in peace-time considerably lightened the task of transforming the artillery equipment—which, excepting the field-guns and the heaviest high-trajectory guns, was not modern.

*Projectiles: Material and Methods of Production.*—The cores of modern artillery projectiles were made from Martin steel by the Ehrhardt pressure process. A material rich in manganese was desirable, and especially one which should be reasonably workable and not liable to cause much waste from rejections. This system of manufacture by means of shell-presses, and, for larger calibres, by drawing from rough billets of metal, required special establishments. The production was therefore confined to specially adapted factories.

In Germany, soon after the beginning of the war, a larger number of firms was available. Before the war, in the latter country, 13 firms were available for the manufacture of the pressed-steel shells for the newly constructed experimental guns. There were no more during the early months of the war.

When, after the first few weeks, the unforeseen extent of the demand for munitions was realized, both States had to depart in some measure from the approved methods of manufacture, because it became necessary also to utilize factories not equipped with presses. Between December 1914 and the middle of 1915 production began of shells of grey cast-iron for light, and of cast-steel for medium, calibres. About the same time began the greatly increased demand on the part of the troops for explosive shells in place of shrapnel, which was of very little use in position warfare. It was believed that the necessity of the moment was thereby satisfied, but, as might have been anticipated, production on this scale did not in the least respond to the demand. While the shells of Martin steel, formed by pressure, could sustain a firing stress of up to 50 or even 65 kilogrammes to the square millimetre without further treatment, the limit for the cast-iron shells was at the most 25 kilogrammes to the square millimetre. Moreover, the cast-shells could not be secured against faults occurring in manufacture. The so-called water-pressure test to which, in both Germany and Austria-Hungary, the finished cast-shells were submitted in the acceptance test, really served no purpose except that of silencing the bad consciences of the experts. The consequence was that these shells had to have their walls considerably strengthened, and to be shortened, thereby reducing the proportion of the explosive. Moreover, the risk of explosions in the bore forbade the employment of powerful modern explosives as filling, and caused the adoption of much less effective safety explosives such as dynamon, etc. These shells, therefore, proved entirely inadequate, and their production was in fact soon abandoned owing to the number of guns damaged by the splitting or bursting of the barrel. It was contrived, instead, to effect a substantial increase in the output of shells formed by pressure.

The ever greater demands made on the munitions industry, which had to share its raw material with other departments of war supply, made it necessary to employ Thomas iron in addition to Martin steel, and, as ferro-manganese was scarcer in Austria-Hungary after the loss of the Jakobeny mines, to reduce the proportion of manganese in the metal. The chief disadvantage of this was that more defects occurred in the manufacture and so many shells were rejected as seriously to reduce the output.

Nowhere did the harmfulness and illogicality of using inferior materials and cheaper processes manifest itself so plainly as in the manufacture of munitions. The war showed clearly that fewer munitions of good quality are much to be preferred to a larger supply of inferior stuff. For nothing so greatly strengthens the *moral* of the enemy and weakens that of the home army as ineffective ammunition. To this was added the great wastage of gun-barrels (from barrel explosions) with the attendant danger to the men serving the guns. The troops lost faith in their weapons, and were inclined to overestimate the enemy's artillery and underestimate their own.

*Acceptance Conditions.*—The kinds of material to be used in shell-manufacture (for test-pieces) were determined in peace-time. For shell-steel a tensile strength of 80 kilogrammes to the square millimetre and an elongation of from 7 to 15 per cent; for shrapnel-steel a tensile strength of 80 kilogrammes to the square millimetre and a 12-per-cent elongation. For shells subjected to high pressure for certain guns exceptional strength was required. In Germany particular attention was given in the tests to the limits of extension. As a rule, none of these specifications was modified in war, except in the case of cast-iron shells. Indeed, the testing of the shells was based even more than in peace-time on their shooting. This became, in fact, the only essential test for shrapnel. Any modification of the conditions laid down and tolerances admitted was only intended to facilitate the necessary mass-production, and no sacrifice of quality was accepted. Several over-careful peace-time stipulations could be dropped without scruple. In those cases in which alloy steel was prescribed as the shell material, unalloyed steel came to be admitted when the super-heavy howitzers began to be used for man-killing purposes (especially in the Carso), as such shells needed no hardening process.

An investigation into the causes of the explosions in the bore, which were the source of much anxiety, showed conclusively that they were seldom to be attributed to the shell-bodies as such, and were therefore usually due to set-up, which in many cases could be very simply obviated by machining down the body. This was the case, for instance, with the Austrian 10-cm. cupola howitzer. The great influence of the brevity of the single effort of resistance required of a shell was demonstrated in an experiment with shells weakened by having the greater part of the circumference sawn through; these were fired with very heavy charges, and all were successful, though the pressure on the dangerous sections must have been greatly in excess of the normal amount. Experiments showed that the calculated admissible pressure on the shell body was far less than that which occasionally occurred without rupture.

In reality, the behaviour of the shell in the bore is ill-understood. The pressures to which the shell is exposed cannot yet be mathematically formulated. The calculations made have only an empirical basis, albeit indispensable. The chief thing is that the material should be of uniform consistency throughout.

*Form of Projectiles.*—In peace-time the measurements—calibre-length, form of head, base—were usually alike in Germany and Austria for modern types of shell; *i.e.* average length, 4 calibres; radius of point about 2 calibres. Those of the medium field army artillery were not very different.

For newer types of gun, *i.e.* the Austrian medium 10·4-cm. and 15-cm., and the German 15-cm. more slender forms were adopted, and consequently the value of improvements in the projectile was more and more recognized, especially in Germany. In order to obtain, with a like weight of shell, the slenderer form and greater calibre-length and at the same time the distribution of mass best suited to rotation, the shells were fitted with ogival caps of thin sheet-metal. These could be removed for the manipulation of time fuzes. The gain in range was 30 to 40 per cent in Germany; in Austria, with the 15-cm. auto-gun it was only 12 per cent. The difference was due to the variations in the ballistic quality of the original shells. Similarly, good results were obtained by Germany for small calibres with the so-called C. shells. The form of these was very carefully defined, and incidentally incorporated a principle which was already being applied by some makers in peace time—the streamlined base. The tests carried out showed the influence of these improvements to be only sensible at muzzle velocities of 500 m/s and upwards.

In certain of the heaviest high-trajectory guns the shells used in field warfare were substantially lightened, so as to obtain a great range without over-straining the gun by use of a heavier charge.

*Painting of Shells.*—While the German shells were nearly always streaked with paint, those of the Austro-Hungarian army were left bare except for marks of identification. The painting appears to be more useful for this purpose than as a protection against rust. Before the war various experiments had shown that the formation of rust proceeded under the paint. Moreover, the lack of pigments enforced their economy in Austria-Hungary.

*Driving-Bands.*—Before the war copper was invariably used for driving-bands. Earlier experiments with cupro-nickel and other alloys led to no result. The size and number of the rings and bands employed are determined by the pressure. An effective pressure on the driving edge of from 400 to 600 kg/cm² was found to be best. The form of the rings was only governed by the necessity of good seating of the shell in the bore and by loading convenience. In the case of heavier direct-fire guns a backward strengthening of the bands towards the rear or a gascheck may be advantageous for sealing, according to the shape of the chamber.

The problem of material became especially important when the scarcity of copper began to be felt. The demand could not be met by the internal production, even with the addition of the metal of commandeered domestic articles.

None of the substitutes employed was really of much practical utility. In both Germany and Austria-Hungary the use of a very soft iron resulted in a wearing-out of the barrel after from 60 to 80 shots. Better results were obtained with a pure iron made by an electrolytic process (electrolytic iron), which Germany succeeded in putting to good use as driving-bands; it was, however, difficult to produce in large quantities, and its employment was limited to this one purpose, for which it ranked next to copper in suitability. The wastage of barrels was not excessive. Paper substances gave tolerably good results both in German and Austro-Hungarian experiments; but the fixing of the paper rings on the shell was very troublesome and not always certain. Besides, the paper had a grinding action on the interior of the bore and led to rapid wear.

A compressed zinc-aluminium alloy, very easily worked, was employed to a great extent, as a substitute for copper, with a thin ring behind or in front of the ordinary zinc band which was of the usual form. While in Germany an extensive use of these driving-bands was being made in 1917, Austria-Hungary from that year onwards effected an increased production by using a hollowed-out gascheck of copper behind the zinc. This, however, was not used in great quantities because at that time the output of ammunition was not sufficient to absorb the copper bands already in hand. The zinc alloy was not really satisfactory, or at most only with the small charges of light howitzers. With more powerful charges the zinc bands were considerably burned through, the sealing was inefficient, and the greatly increased dispersion seriously impaired shooting.

*Shrapnel and Shell-Shrapnel.*—The equipment of the field-artillery guns with shrapnel and explosive shells respectively was based on the view prevailing before the war that shrapnel, with its more extended effect and lesser dependence on precision, was the best projectile for use against troops. For the light field-guns the proportion of shrapnel was very high. Various efforts were made to arrive at a "universal" shell, in order to simplify ammunition supply. From this attempt arose the various types of H.E. shrapnel, the fuse of which was so contrived that the projectile could be made to act either as shrapnel or shell. In the end the "universal" shell was accepted by Austria-Hungary alone of all the great States. The Ehrhardt H.E. shrapnel was found the best and was adopted. Three factories were set up for its manufacture before the war. The projectile had pressed into the shrapnel body a head acting like a shell. The bullets were packed in with *trotyl*. In time shrapnel fire the shell acted as ordinary shrapnel, and also, on the head striking, as a small explosive shell. The effect

of this head against shields was very satisfactory; moreover, the bursting of the head considerably aided the ranging. In percussion fire the effect was not equal to that of a modern high-explosive shell, but greatly surpassed that of ordinary shrapnel. The manufacture was only slightly more troublesome than that of other shrapnel, and the shell effect of the head and the assistance it gave to ranging more than compensated for this, so that, on the whole, the shell was considered satisfactory. Universal shell, in any case, was no substitute for H.E. shell, and as time went on and the use of shrapnel became more and more limited to particular episodes of fighting, universal shell, like ordinary shrapnel, diminished in importance. In practice, however, in both armies and especially in the Austro-Hungarian, a large proportion of the ammunition had still to be in the form of either shrapnel or universal shell, owing to the lack of material, and particularly of explosives. And the practice of packing explosive between the bullets of the universal shell had to be abandoned.

*Iron Bullets.*—The want of lead caused a substantial falling-off in shrapnel production. In 1916 the manufacture of iron shrapnel bullets had already begun, and from 1917 onwards leaden bullets practically ceased to be made. The bullets were cast or pressed. The former displayed undesirable ridges and corners; the latter were more difficult to produce in large quantities. Another disadvantage was that not only did the lesser specific gravity of the iron bullets in relation to that of the lead-antimony bullets result in a lesser power of penetration, but a much smaller number of the former could be got into a shell than of the latter, which, being smaller and fitting closer together, permitted full utilization of the space. It followed from this that the total weight of the shell was less, so that shooting with the existing sight-graduations became complicated and produced different results. The packing in with explosive, in the Austro-Hungarian universal shell, became impossible with iron bullets, because of the danger of prematures.

*Coloured Smoke-clouds.*—The effort to render the smoke of exploding shrapnel more visible, even over snow-fields, led, in Austria-Hungary, to the use of a red colouring matter (oxyhydrate of iron), which made the smoke-burst half red. This colouring also facilitated the keeping of a due distance between the shots. In Germany various devices were employed for colouring the smoke of certain shells.

*Fuzes and Ignition.*—The fuzes ordinarily used by both armies in time shrapnel fire were T and P fuzes of the setting ring class. They were used both for shrapnel and for time fire with nose-fuzed H.E. shell. After the abandonment of H.E. time fire (which was dictated by the necessity of simplifying the mass-production of one of the fuze parts) a simple explosive shell fuze was adopted.

The Austro-Hungarian artillery employed base-fuzes much more than the German. That most in use was one of Krupp manufacture which had an effective ball-safety. The design of Austrian base-fuzes differed considerably from that of German as regards the transmission of ignition. Base-fuzes proved quite as satisfactory as nose-fuzes in the war. Explosions in the bore were no longer caused by fuzes, as they appear to have been in peace-time.

Soon after the war opinion changed regarding the relative merits of shrapnel and explosive shell. The estimate of the value of the explosive shells in percussion and time fire likewise varied from time to time according to the nature of the ground being fought over. While H.E. effect was almost entirely lost in the soft soil of Galicia and Poland, on rocky ground (and more especially on the Carso) the effect of this kind of fire was intensified by the splinter effect of the stones and, moreover, blinds seldom occurred. Efforts were directed towards the production of a sensitive instantaneous fuze, especially in the western and eastern theatres of war, where also time explosive fire was more in demand than in the Italian theatre.

Germany's *sensitive instantaneous fuze*, produced in 1916 and 1917 (*see* AMMUNITION), was of an extremely simple pattern and safe in the bore. It was not very satisfactory, however, for flat angles of descent, being apt to go blind in such cases. By the end of the war Austria-Hungary had also produced a sensitive fuze, constructed on similar principles and exhibiting similar defects. These fuzes were, of course, necessarily nose-fuzes. A device for bringing into the system a long or short delay element, or both, can easily be added; but the question of the instantaneous fuze is still open.

In the western theatre flat-trajectory ricochet fire with long alloy fuzes was very successful on suitable ground. It served as a substitute for H.E. time fire, and was indeed more effective when the burst occurred at the proper height. However, it depended on the coincidence of several favourable conditions. Experiments were made with *mechanical time-fuzes*, especially for use with anti-aircraft guns, in order that the igniting composition of the time fuzes should not be affected by atmospheric conditions. The best results seem to have been obtained with those made by the watchmaking firm of Junghaus, which brought out designs both in Germany and Austria-Hungary. The Krupp model was driven by spring power; the Junghaus by a centrifugal device. The success of these designs was not in proportion to the costliness and difficulty of manufacture. These fuzes were but slightly superior to the time-composition fuzes, and on the other hand introduced new sources of error. Moreover, their manufacture depended on the existence of a large-scale clock industry capable of mass production.

*Substitute Metals.*—The lack of brass, of which fuzes were nearly always made, necessitated the use of substitute metals for this purpose. The best results were obtained, for a number of the fuze parts, with an alloy of zinc and aluminium. Iron was also satisfactory for fuze bodies and other portions. Only certain especially delicate interior parts (such as safety-ferrules) were made of brass as before. Both Central Powers soon became very successful in the employment of other metals for fuzes, so that the use of these substitutes might well be continued without disadvantage even in peace-time, when normal supplies of raw material are available.

*Explosive Charges and Their Filling.*—Before the war *trotyl* (T.N.T.) had been completely adopted for shell fillings in both Germany and Austria-Hungary. This was inferior to *ekrasit* (picric acid) in explosive power, but its greater insensitiveness to shock, and also the fact that its preparation was both easier and less injurious to health, gave it a considerable advantage.

While Germany, owing to the high development of her chemical industry, already had, in peace-time, several establishments for the manufacture of *trotyl*, Austria-Hungary was dependent on Germany for this substance at the outbreak of the war. A few months later she began to make her own *trotyl*, and Germany set up a number of additional factories; nevertheless, the supply was soon outdistanced by the enormous demand, owing, once more, to the scarcity of raw material. Not only had recourse to be had to picric acid (known in Austria-Hungary as *ekrasit*), but a number of other explosives had to be produced from the available raw materials and used as artillery fillings. Some of these were difficult to work, some not over-safe, some inferior in effect. The demand continued to increase, for with the ever-growing multiplication of new fighting devices, such as trench mortars, grenades, air bombs, etc., the use of explosives was being continually extended.

In Germany the satisfaction of the immense demand was less difficult than in Austria-Hungary, where the army administration was dependent for its explosives upon two public and two privately owned factories. At the beginning of the war, with the exception of one privately owned *ekrasit* plant and one ammonal works, there were no factories for ammunition explosives in the country.

*Trotyl* was almost invariably poured directly into the shell cavity. To prevent crystallization the stuff was filled under pressure, and constantly stirred till solid. The exploded cavity was made by boring. The projectiles filled by this method proved highly satisfactory, and it was used up to the end of the war for all shells subjected to high stresses, as far as the supply of *trotyl* permitted. Complaints were made only against "crude *trotyl*," which contained insufficiently nitrated portions and was apt to "exude."

The manufacture of picric acid necessitated great precautions because of high melting-point, and was also very inconvenient by reason of the injurious nature of the fumes and dust. Hence *ekrasit* was not poured into the shell in a molten state like *trotyl*, but after the addition of a "phlegmatizer" (*e.g. mononitronaphthalin*), was filled in in large masses and pressed down with wooden stemming rods. Later on, in order to simplify the process, it was made into compressed blocks, and these were fixed into the shell with paraffin and resin. For the larger calibres a combined picric and cast-*trotyl* filling was used. Picric acid was thus restored to its earlier importance in shell-filling, and, in spite of less strictness in inspection conditions, proved as satisfactory as *trotyl* up to the end of the war.

The immensity of the demand soon made new expedients necessary. In Germany *dinitrobenzol* was used to some extent. It answered well when a more vigorous substance was used with it to start detonation (*trotyl* blocks). Its troublesome idiosyncrasies in working were considerably lessened by the use of suction apparatus. *Trinitro-anisol*, more powerful than *trotyl*, but also more easily exploded, was also used in Germany. Because of its unpleasant physiological effects, it was, however, employed only for the projectiles of trench mortars and trench munitions, and for naval mines.

The most important of the measures taken purely for economy was the use of ammonium-nitrate explosives. These are made by mixing finely powdered ammonium nitrate into the molten mass of a nitrated substance. Hence the explosives of this class actually used[1] were based on *trotyl* or *dinitrobenzol* in Germany and *trotyl* only in Austria-Hungary. By this method explosives very little inferior to *trotyl* could be obtained and the total production considerably increased. Although the sensitiveness to shock was found to be rather greater, the manufacture was almost as convenient as that of *trotyl*. Picric acid could not be treated in this way.

In Austria-Hungary there arose a very extensive demand for *toluol-ammonal*, which consisted of ammonal with from 10 to 30 per cent addition of *trotyl*. The composition was first compressed into blocks, which were inserted into the projectile in cardboard tubes. Solid-filling by means of molten paraffin or *trotyl* poured into the interstices between those tubes did not prove satisfactory in the Austro-Hungarian base-fused shells, as set-backs occurred on discharge. For this reason the compressed blocks were inserted without the cardboard tubes, and were made to adhere to the shell-wall with a composition of lime, resin, and paraffin, or by means of cast *trotyl*. The best results were finally obtained by the use of pitch. Hot pitch, in the form of dust, was sprayed onto the shell walls (Fritsch's process). In the case of a few large calibres *trotyl* was filled onto a short block of compressed *T. ammonal* secured by cast *trotyl*.

[1] Called *amatols* in Great Britain.

In Germany the cardboard-tube method, on the contrary, answered very well indeed with *ammonal* explosives. The explanation lay in the very different design of the Austro-Hungarian base-fuzed shells, which made them very liable to accident when the explosive was badly settled in the shell cavity. However, *trotyl*, *ekrasit* and 60/40 *amatol* remained the most satisfactory explosives from the point of view of the manufacture, and hence the least open to objection.

As *substitute explosives*, *ammonium-nitrate explosives* and *chlorate explosives* were used. Among the former, *dynamon* was used in cast-iron shells, for reasons of safety as already explained. The scantiness of the smoke produced and the fact that ignition depended upon the density of filling caused this substance to be regarded with disfavour. However, *dynamon* and (in Germany) a number of similar safety explosives were used in trench-mortar shells and grenades, and for engineer munitions, with good results.

The chlorate mixtures, put out under various names (chiefly in Germany) and intended for various military uses, soon disappeared again in consequence of numerous disasters, which could be traced to over-sensitiveness on discharge, filling dangers, and their liability to disintegrate. The perchlorate explosives were satisfactory as regards safety. They were used with good results for certain trench-mortar bombs, but only in Germany. A radical measure of economy was found in the use of "economical filling." The portion of the shell cavity nearest the fuze was filled with the selected explosive and part of the remaining space with pitch. By the use of very powerful ignition this process gave far better results than might have been expected, but it was never used on a large scale.

Notwithstanding these comprehensive measures the lack of explosives, which, at all events in Austria-Hungary, was chronic, greatly hindered the supply of artillery ammunition, almost as much in fact as did the difficulties of propellant manufacture. Both deficiencies were due to the backward state of the chemical industry in that country. Although the needs of Germany were very much greater than those of Austria-Hungary she was always able to respond to them much more quickly.

*Bore Explosions.*—Special care was devoted to obviating the bore explosions which were so disastrous both from the point of view of the command and that of the troops. As has been said (except in the case of the unsatisfactory cast-iron shells), these could very seldom be attributed to the shell-material. In the case of very long high-pressure guns it is possible that shells on the high limits of tolerance were jammed by the action of the so-called *breath* of the barrel. More sources of defect were naturally to be found in the fuze, which must inevitably contain a very powerful igniting composition. In Austria-Hungary detonators were regarded as dangerous. The fear does not seem to have been justified, provided they were properly placed and secured, and due precautions observed, but they are yet another source of weakness in mass-production. At all events, there were few bore explosions with the Austro-Hungarian pressed-steel nose-fuzed shells, which had very simple fuzes without detonators—fewer, in fact, than occurred with the German shells. The Austro-Hungarian base-fuzed shells had the defect that absence of a detonator necessitated the adoption of a long exploder-gaine, which greatly increased the difficulty of securing the explosive charge against the shock of discharge. Herein also lay a cause of the above explosions, which at one period were occurring with disquieting frequency. It was at first very difficult, especially with *toluol-ammonal* fillings, to fix the compressed blocks to the shell-wall firmly enough to prevent their setting back, and disturbing the ignition arrangements. Later on, these causes were discovered and almost entirely eliminated.

These special factors being left out of the question the number of bore explosions cannot be considered to have been abnormal, either in Germany or Austria-Hungary. In peace-time it was reckoned that in every 10,000 H.E. rounds there would be at least one unpreventable "premature." For example, during the Austro-Hungarian gun-practice in the years 1912 and 1913 the percentage was as high as 0·04; whereas in July 1915, a particularly bad month, the percentage was only 0·023 and in June 1915 only 0·012.

These explosions may be ascribed chiefly to the impossibility, in quantity production, of superintending the work so minutely as to eliminate altogether the possibilities of error in the manufacture of the fuzes, the thorough sealing of the shell-bases, and the filling of the bursting charge. The proper handling of the ammunition, in the depots, during transport, and in loading, was also an important factor in safety.

*Cartridge Cases.*—Except in a few old types of gun the Austro-Hungarian artillery always used cartridge-case obturation. All flat-trajectory guns of small calibre used fixed ammunition. All mortars and howitzers, and especially all large calibres, had separate loading. The idea that this unfavourably influenced the rate of fire had led to the attempt, in peace-time, to use fixed ammunition for light howitzers. While the fore part of the case was joined to the shell the nether part was detachable. Later on this method of loading fell into disfavour because of its complication. When the demand arose for reduced charges for field guns, in order to spare the guns and also to adapt them for firing from concealed positions, this problem was taken in hand more seriously, and in Austria-Hungary a very simple and satisfactory contrivance was found, though never made in large quantities.

At first the cartridge cases were always made of sheet brass by drawing and pressing. The cases were recovered after firing and used again, re-manufacture seldom being necessary; but although this salvage enabled a large part of the need of cartridge cases to be met, it soon became necessary to resort to substitutes, owing to the universal lack of brass. At first the deficit was made good by the use of iron bases and brass sides, joined together in a very simple manner. Generally speaking, cartridge-case obturation proved much more trustworthy in practice than was expected. In fact the two-piece construction eliminated one of the greatest sources of defect in the single brass case, *i.e.* the weakness at the bend between the base and the sides. The danger of burning through in this region was insured against in the design. The kind of material used for the base was not of much importance, cast-iron proving quite satisfactory. In the end iron-plate was used for the cylindrical part, even up to the heaviest calibres, except for use in long-range guns. Conspicuously good results followed, especially in Austria-Hungary, where, finally, a simple case of sheet-iron bent round, with an inward flange at the lower end, was used for the cylinder. It would stand being fired from 10 to 15 times without re-manufacture. In Germany, also, iron shell cases fully satisfied the requirements, and could be fired 5 or 6 times.

These iron cases replaced the brass ones altogether. The manufacture was simpler. Only the junction of base and shaft needed careful working. Bruises and dents did not matter in the rolled cases; they were smoothed out in firing by the expansion of the gases.

The prevention of rust of course was a difficulty; but this was less important in war, owing to the short time that elapsed before the shells were used. Excellent results were obtained by dipping the cases in oil raised to a temperature of about 100° C., and repeating the process several times. The examination in Austria, in June 1921, of ammunition which had been stored without any special care showed that almost all the cases so heated were still serviceable.

The powder charge was inserted into the cartridge cases in bags of raw silk. As this expensive material soon became scarce, substitutes had to be employed in charges made up of separate elements (with cartridge cases the bag was omitted). Artificial silk proved a satisfactory substitute. Paper substances were also successful in the parts lying away from the primer. No exhaustive trials to determine the chemical effect of the powder on paper were carried out.

*Propellant Powder.*—The smokeless powder used in the German army as a propellant was almost invariably a nitrocellulose powder. Nitroglycerin was used only in small quantities. In Austria-Hungary, on the contrary, pure nitrocellulose powder was the propellant of small-arms ammunition only. All other propellants were nitroglycerin powders containing a high proportion of the nitroglycerin (up to 40%). The particular composition and the form varied with the purpose in view and the gun concerned.

The Austro-Hungarian guns had in general a smaller chamber space than the German, with a greater energy-content in their powders. The higher combustion temperature of the nitroglycerin and the stronger flash had an extremely bad effect on the interior of the bore, especially when substitute materials were used in the composition of the powder. The use of this powder in the field guns was the main cause of the great wastage in these compared with the German field guns. The Austro-Hungarian steel-bronze guns resisted better; not so, however, the steel guns which came into use because of the scarcity of metals, and of bronze in particular. When, later, a change was made to a powder poor in nitroglycerin, the unsuitable size of the chamber created great difficulties in determining the proper charges.

No new powders were used or produced during the war by either Power. Some simplification of processes was all that was effected. But the German chemical industry energetically attacked the problem of producing the basic products used in powder manufacture, and in this domain new combinations were made and new ways opened. Among partial novelties may be reckoned the development and improvement effected in the preparation of ammon powder, which had been experimented with in Austria before the war, and even used in her navy for a short time.

The use of substitute raw materials had a considerable effect on the production of powder, and some effect, also, on the results obtained by its use. Special importance attached to the nitration of wood cellulose as influencing the quality of the powder.

At first it was impossible to get rid of the papery consistency of the wood cellulose, but, later, direct nitration was successful. Variation in the viscosity of the wood cellulose or in the preparation of nitrogen-content necessitated variations in the dimensioning of the powder. The unequal nitration of the cellulose was particularly marked and produced differences in the degree of nitration which led to unequal gelatinization and a varying energy-content.

The nitrate difficulty disappeared when it became possible to obtain nitrogen from the air in large quantities; but the victory over the alcohol, ether and acetone shortage was won with more difficulty. These substances were required for gelatinization. The acetone obtained from wood distillation was mostly produced in Austria-Hungary, which partly supplied Germany.

In consequence of the great demand other products of wood distillation had to be brought into use, and the purity of the acetone suffered. Instead of the solvent method, therefore, the roller or

ballistite method was adopted for nitroglycerin powder, and resulted in an economy of material.

Glycerin substitutes were the most difficult to procure. Glycerin made from sugar was inferior to that made from fats. Moreover, sugar also was scarce. But nothing else had quality requirements.

The inferior purity of the materials, already referred to, produced a number of evils. Some of these did not prove any particular drawback in use. A more serious matter, however, was deficient or unevenly distributed gelatinization of the wood cellulose. These irregularities were shown externally by the presence of little white spots, and resulted in the detonation of the powder on discharge. Only by the most drastic inspection could these mishaps be avoided.

A still greater disadvantage lay in the reluctance of these war powders to ignite, which endangered the lives of the gunners by hang-fires. For this reason, in Austria-Hungary, the use of a black powder-priming, which had been discarded in peace-time, was resumed, with certain precautions.

*The lesser inflammability* caused a quantity of unburned powder to remain in the fore-part of the bore after firing. This was especially the case with the slow-burning tubular powders. In certain guns this occurred in a regular manner; the same amount was always left unconsumed and the effect on the accuracy of the shooting was thus negligible. But if the amount varied the shooting was ineffective.

But the worst consequence of inferiority in the quality of powder was the increased number of barrel-burstings. For reasons already given this was most frequent in the Austro-Hungarian long guns. In the steel-barrelled field guns the length of the gun's life diminished from 1,800 shots to 800—an impossible state of things. The advantages of the howitzers and mortars here becomes apparent. The 15-cm. howitzer lasted out 14,000 shots, and the 30·5-cm. mortar as many as 2,500. The German guns manifested about the same endurance, thanks mainly to the less eroding nature of the nitrocellulose powder employed.

To find a remedy became an urgent necessity in Austria-Hungary. As one expedient reduced charges were introduced to be used in lieu of the service-charge when the nature of the fighting permitted; as another, following the German example, recourse was had to the preparation of a powder poor in nitroglycerin. The limited size of chamber did not permit the use of pure nitrocellulose powder; but finally success was obtained with powders containing only 13 % and 25 % of nitroglycerin. The life of the guns rose forthwith to 12,000 shots. But the output of powder declined, because a large number of the batches produced did not give the required density of loading. However, the method was advantageous owing to its economy of glycerin, which was so scarce.

In Germany good results were achieved with ammon powder, which, made by the new method, partly took the place of nitrocellulose powder. It was soon employed for all calibres. This highly hygroscopic powder could be easily made damp-proof in metal cartridge cases. Where—as, for instance, in certain of the foot-artillery weapons—the powder was made up in bags, the ammon powder was enclosed in a layer of nitroglycerin powder. Ammon powder had the great merit of producing little flame at the muzzle.

The bright flashes of the large calibres, which were so inconvenient at night, by means of anti-flash were reduced by "flash-dampers," *i.e.* layers of common salt in front of the powder, which covered the light by producing a large volume of smoke. These were added to the cartridges immediately before firing. The manufacture of black powder remained unchanged, and as the output was comparatively small the production was unaffected by the scarcity of raw material.

In Austria-Hungary, especially, all these difficulties, combined with the small output capacity, seriously interfered with extensive mass-production, and moreover, as the powder production nearly always lagged behind that of the other munitions, it was necessary to make use of insufficiently settled and ballistically unstable powder. Moreover, failure to issue the powder charges in batches according to manufacture was the cause of much bad shooting, which the troops erroneously attributed to defects in the guns or the shells.

*Gas Shells.*—The use of gas in artillery shells, and with special kinds of apparatus, was one of the novelties reserved for the World War. After a semi-experimental stage in the early months of the war the ultimately general and comprehensive employment of gas shell had its beginnings in the cloud method and in the trench-mortar gas shell. It was anything but popular with the German troops, who did not in fact appreciate its value until after long experience.

It was inevitable that the inadequate chemical resources of Austria-Hungary should here play a subordinate part beside the fully matured industry of Germany, whose chemical development had, moreover, been powerfully stimulated by its activities during the war. The Danube monarchy was absolutely dependent on Germany in this respect. For this reason, and also because the enemies mainly confronting the Austro-Hungarians made but small and ineffective use of gas, this form of warfare was less developed on their front, and was not properly appreciated by the troops till nearly the end.

In the early months, to the middle, that is, of 1915, the Austro-Hungarian artillery was provided with lachrymatory shells in very limited numbers. The filling was *T-stoff*, a preparation of bromine. The troops did not understand their use at all; they were never fired in large quantities, and very little was achieved by their use.

In Austria-Hungary the issue of gas shells, *i.e.* of B. and C. shells, was begun in 1916 and 1917, when the newly constituted special battalion were seen to have obtained no appreciable results with cylinder gas.[1] The B-gas was *bromo methylketone* or *bromacetone*, corresponding to the German B-gas. The C-gas was *bromo-cyanide*. When C-gas was used the shell walls had to be coated with lead. But if the gas may be called efficacious the shells were not so. The chief cause lay in the fact that effect was not to be expected unless large quantities were used, and the available supply did not allow of this. The troops, therefore, thought very little of this means of fighting, and with reason.

The effect of the German gas-shooting in the West, and especially the brilliant results obtained with gas against the enemy artillery and even against high-sited positions by the German batteries in the combined offensive of Caporetto in 1917, spurred on Austria-Hungary also to the manufacture of gas shells in large quantities. Not only was the production of the B. and C. shells increased, but phosphorus shells were also made, and ultimately the gases adopted were those used by the Germans (*blue-cross—yellow-cross—green-cross*). As far as the use of these gases was concerned Austria-Hungary was dependent on Germany for her material to the end of the war. Except in the case of the shells previously referred to, the Austro-Hungarian gas shells were always filled in Germany, as the home establishments were not completed. Hence only Germany's procedure need be considered here. The following information is taken from Lt.-Gen. Schwartz's *Technik im Weltkriege*.

The first German shell with chemically active gas appeared in October 1914, and was the *Ni-geschöss* of the 10·5-cm. field howitzer; the filling consisted of double salts of *dianisidin* firmly pressed in between the bullets, and acted as an irritant when pulverized. The effect was inconsiderable, being limited in range and of short duration. In Jan. 1915 much more effective gases—such as *xylylbromide* (T-gas) and *mono-* and *di-bromethylmethylketones* (B-gas)—were used at first in the 15-cm. howitzer shells, afterwards for trench mortars. With these only local effects of limited scope could be obtained. The necessary mass-effect could not be attained because of the limited number of howitzers and trench mortars, but chiefly because the best method of working had not yet been discovered.

For the T-gas shells, which could not be used in very cold weather, were substituted the T- and B-gas in the "T-green" shells, partly because the mixture answered better. In the summer of 1915 began the use of K-gas—*chlormethyl-chloroformate*—which differed from the T-gas in its lower persistency and its greater irritant action on the organs of breathing. This indicates the reason of their respective uses in defence (T-gas) and attack (K-gas).

These shells, which were intended to have splinter effect as well, contained a 1·5-kgm. charge of *trotyl*. It was a drawback in the manufacture that in order to protect the shell-wall the gas had to be enclosed in leaden flasks secured in paraffin or magnesium cement. Later on porcelain was used. They contained 2 kgm. of the gas.

There followed the period of cylinder gas and of projectors which were first used by the British. Even on the western front the cloud-gas did not fulfil expectations; the gas-bombs of trench mortars, however, were used with satisfactory results throughout the war.

During the summer of 1916 the *green-cross* ammunition was introduced. In that year the German artillery, following the example of the French, at last turned to the manufacture of gas shells filled purely with gas. H.E.-effect being abandoned, mass-effects with gas then became possible.

The experiments made led to the adoption of green-cross shells for all calibres. *Per-stoff* (di-phosgene) was used for the filling, which was as poisonous as the phosgene used by the French, but was unaffected by iron and also stable on explosion. The manufacture and filling were both simple. From May 1916 until the end of the war *green-cross* ammunition was in use as offensive material. It permitted of large-scale gas effect without being dependent on the direction of the wind as was cylinder gas.

At first the French mask was ineffectual against it. But they soon contrived an efficient gas-mask, and Germany was obliged to bring forward other gases. These were *yellow-cross* and *blue-cross*. *Yellow-cross*, i.e. *Sym. dichlordiethylsulphide*, which had no actually poisonous properties, was a high-persistency gas and was used to "infect" the terrain for days on end. It was almost odourless and was proof against the action of iron and water. This was the famous "mustard gas." Strict precautions had to be observed in the manufacture of this gas, which was used in all calibres.

The combination of H.E. action with the *yellow-cross* gas action came to be desired for purposes of surprise. This brought into existence the *yellow-cross* H.E. shell, in which the chemical and the explosive charge were separated by a diaphragm.

*Yellow-cross* was at first used in combination with *blue-cross* in the defensive battle in Flanders in July 1917, and produced a great effect. The latter (*blue-cross, diphenylchlorarsine*) was an irritant which proved effective in penetrating gas-masks, the Germans one included. The effect was to force the enemy to take off his mask, and

[1] A gas attack, made from the region of St. Michele, near Gorizia, in the summer of 1915, had indeed (as was averred by the prisoners taken) a very great effect; the Italians lost a thousand men killed or overcome by the gas; the circumstances, however, prevented any extensive tactical results.

to expose himself to the effect of *green-cross*. The *blue-cross* irritant acted as a fine cloud, with which it was very difficult for the filter of the gas-mask to deal. *Blue-cross* also combined gas and H.E. effect, and the beginning of the gas attack was covered by the use of a diaphragm, as in the *yellow-cross* H.E. shells.

The German experience with gas-ammunition was excellent. On their side no instance is known of the enemy being able to advance over ground infected with *yellow-cross*. No attack ever made with "*parti-coloured-cross*" (*blue- and green-cross*) in a favourable wind failed to paralyse the enemy artillery either entirely or in great part, even when they were under cover, during the critical hours.

*Special Ammunition.*—At first the gas shells were also reckoned as "special" ammunition. Later on, however, they came to be considered as part of the ordinary artillery ammunition. The extent of their employment, at all events, in the case of the Germans, often equalled or even exceeded that of the ordinary explosive ammunition. The *ricochet* shells were used to obtain a specially retarded action.

Against tanks the German artillery used a shell with an armour-piercing head, rather more effective than the ordinary nose-fuzed shell. The projectile had a massive armoured-steel head which was fitted with the steel shell body, and was set in motion by a fuze placed beneath this—*i.e.* a central fuze.

For anti-aircraft purposes projectiles with tracers were used; experiments with these had been made in peace-time. Krupp produced a model which proved very satisfactory, especially in certain small anti-aircraft guns. The path of a 2-cm. shell was clearly visible from the gun muzzle, that of a 3·7-cm. to 1,500 metres. Tracers were not, however, much used with field guns and large calibres, and were not greatly liked by the anti-aircraft batteries.

Against airships and balloons inflated with gas, a balloon incendiary shell, also of Krupp manufacture, was employed. The projectile which acted like shrapnel and was provided with a time-fuze, shot lumps of incendiary composition out of the shell-case. The old incendiary shrapnel was little used. For signal purposes—*e.g.* to demand the opening of fire on particular points—shrapnel with various-coloured-smoke producers were used.

In accordance with the demand of the troops message-carrying shells were made. These shells contained written communications, and, on exploding, gave off conspicuous smoke and flame; the message came to ground either by means of a parachute or in a receptacle which broke as it fell. They served to connect points cut off from one another by enemy fire or otherwise.

*Minenwerfer Munitions.*—The Wurfmine (thrown mine), *i.e.* the trench-mortar shell which was already included in Germany's equipment at the beginning of the war, differed from the artillery-shell principally in its considerably increased explosive charge. The "efficiency" rose from 30 to 40% of its total weight. Consequently the wall of the shell was thinner as the small propellant charge made less demands on its strength. The shape of the projectile was similar to that of the artillery-shell, except that the shape of the head was not of great importance. The shell material was, generally speaking, similar to that of artillery munitions, but economy was more in evidence here. Thus constant use was made of cast-iron in certain types of shells to the detriment of the essential feature, viz. the increased proportion of explosive. In order to economize the most valuable explosives for the artillery-shells, use was soon made of ammonium-nitrate explosive, "safety" explosives, and such like. In Austria-Hungary, for instance, hardly anything but dynamon was used. In Germany perdit for heavy bombs and perchlorate for light was resorted to. Such explosives answered very well for these projectiles. Unlike the artillery-shell, owing to their less accurate flight, they required a fuze which would be effective in every position of fall. This was a very difficult problem to solve, but eventually the Papenberg fuze used in both countries and the Skoda fuze in Austro-Hungary were evolved. In the first and simpler types of mortar a cord friction-lighter was used as time-fuze. The German standard pre-war minenwerfer had percussion fuzes.

The explosive charge was started in much the same way as in artillery-shell with picric-acid filling. Later on, to economize steel, the gaine was made of cardboard cases of several thicknesses. As the *mines* were not air-tight, the great hygroscopicity of the ammonium-nitrate explosive caused a dampness after a time, which affected the cardboard casing and caused a mixing of the two explosives, with the consequent danger of spontaneous explosion.

According to the type of mining weapon—pneumatic, smooth-bore, rifled muzzle-loader or rifled breech-loader as the case might be—the method of obtaining rotation was similar to that in the artillery-gun, or to old types of "stud" rotation, or were simply gas checks which had only to seal. Some types of muzzle-loader bombs had concertina-like compressible plates of thin iron which were forced or discharged through the grooves. Some few projectiles obtained stability in the flight by means of vanes. In the end it was the rifled mortar and, for the heaviest calibres, the rifled muzzle-loader which held the field. But a substitute material was always used for the driving-bands of *mines* mortar bombs—for a short time zinc-aluminium, and then only soft iron, less injurious to the bore.

For the propellant charge smokeless cube and flake powders were used, and in some types for a short time black powder. The charges were comparatively small. To meet the demand of the troops a propellant charge of compressed air was used in some types up to 20-cm. calibre. By this means all smoke flash was avoided and the report considerably lessened. Results, however, with regard to rapidity of fire and the weight of the bombs were not satisfactory, and the supply of compressed air was also very tiresome. In 1917 pneumatic mortars were therefore abandoned. Towards the end of the war an attempt was made to get full value out of the gas pressure by using a stepped chamber and stepped shell body.

While Germany even before the war had included both light and heavy *minenwerfer* in her equipment, it was some considerable time before Austria-Hungary adopted them as a normal weapon. The bombs were at first intended for the destruction of barbed-wire entanglements, but in the course of the campaign their true function came to be that of meeting the demand for additional artillery effect and for great mine effect at short distances. In the first instance various improvised models were made in the Pioneer Parks to meet these needs, particularly in Austria-Hungary at the beginning of the Italian campaigns. Improvised types were also used in Germany at the beginning to supplement the insufficient supply of standard trench-mortars. These types all disappeared when the regular types began to be produced in sufficient numbers. Nevertheless, the experience was a guide to future development.

Later on, trench-mortar bombs were charged with gas. In view of the small results gained by this form of gassing it was abandoned in 1917 in favour of gas "projectors." In the case of some special projectiles—*e.g.* illuminant and message-carrying—trench-mortar types proved more suitable than gun types.

The diminished strain on the body, smaller impact energy and comparatively large space available in the shell facilitated the fitting-in of the necessary components for these purposes. Another special bomb was the strongly built armour-piercing bomb which was effective against a 20-cm. armour plate. The difficulties experienced in the production of artillery-shell due to lack of raw materials were intensified in the case of the trench-mortar bomb, which in the table of priority for assignment of material was considerably behind the artillery munitions. And yet, although the conditions were comparatively less exacting as regards quality of material, flight conditions, precision of shooting and effect, their design involved comprehensive work in order to meet the very varied requirements with the simplest ballistic means, manufactured with the simplest tools. The employment of substitutes aggravated the difficulty. For this reason the help of private inventors, which had not answered in the case of artillery munition, here had most successful results.

*Hand Grenades* were practically unknown during the first months of the war; with the institution of trench warfare the need of a simple high-angle projectile was immediately recognized. Both in Germany and in Austria-Hungary the troops improvised hand bombs of a very varied character in the Pioneer Parks. All were time grenades.

Early in the autumn of 1914 the German Army Administration turned out a simple cast-iron ball grenade, which could be produced in any foundry. Later on, to secure improved range, a change was made to the "egg" hand grenade of similar construction. The latter, together with some other types, were in use until the end of the war. At the same time Austria-Hungary produced the "universal" hand grenade, which as early as October 1914 was used by the troops in trench warfare in Serbia. It consisted of a cast-iron body, serrated for fragmentation, and filled with *shrasit*. Ignition was by means of a friction lighter and fuze length and detonation. This hand grenade could be conveniently thrown to a good distance by means of a stirrup-shaped wire "thrower," which could be attached to the waist belt. Later on the hand grenade was the chief weapon of the infantry "assault troops," and to a large extent deposed the rifle from its supremacy. The demand therefore was enormous and production had to meet it. In view of the great burden already placed upon the whole armament industry their design had to be of the simplest so as to bring fresh factories into the effort of production. The classes of explosive employed were the same as those of trench-mortar bombs. In addition to the ever-increasing numbers of "egg" hand grenades Germany also supplied her troops with the "Stiel" (handled) grenades. These stood the test right to the end. Austria-Hungary too proceeded to improve her "universal" hand grenade, and produced from 1915–7 two types of tubular hand grenade. A cardboard tube which served at the same time as a handle carried the friction-lighter, time-fuze length, detonator and burster cartridge. The top was surrounded by a heavy ring of cast-iron for fragmentation. These grenades were all timed for 7–8 seconds.

In March 1917 Austria-Hungary began to use the handled grenade, which formed part of her equipment until the end of the war. It was similar in principle to the German (separate transport of the detonator was, however, not considered necessary). The endeavour to absolutely safeguard the bomber from the effects of a premature explosion of the grenade led in Germany, for instance, to various methods of igniting the fuze length, including designs in which ignition took place after leaving the hand. On the other hand it was desirable to relieve the operator from the disturbing sensation of the burning grenade in his hand. The time-fuze hand grenade, moreover, on account of its slow combustion, allowed of a return throw by a specially adroit adversary. Both countries, accordingly, experimented with a succession of percussion grenades. The difficulty lay in stabilizing the flight to guarantee the right impact and

avoid non-explosion. Streamers, parachute tails, etc., did not solve the problem satisfactorily. Later on always percussion-fuzes were tried. In Germany the Papenberg fuze answered best. In Austria-Hungary, a suitable model was found in the Goldmann fuze.

As the handled grenade was on the whole satisfactory, neither Power failed to keep the output at a high level during the war. Austria-Hungary, indeed, introduced towards the end of the war a percussion hand grenade which differed from the handled in having the Goldmann fuze, but its merits had no final judgment. A few hand grenades were also loaded with chemicals, *e.g. Stoff*.

*Rifle Grenades.*—At first rodded rifle grenades were used, but without really satisfactory results, and eventually Germany took to the discharger cup and a grenade of the V.B. class.

*Grenade Throwers.*—The grenade *werfer* (thrower), although not so simple, met much more fully the demand for a greater range. It was the connecting link with the *minenwerfer*, and indeed was more akin to the latter than to the rifle grenade. Early attempts with throwers of the most varied forms led to no useful results. The first serviceable model was constructed by an Austro-Hungarian inventor. This grenade thrower, called in Germany *Priesterwerfer*, threw cast-iron bombs with percussion-fuzes (usually of the vane class). It is described and illustrated under BOMBTHROWERS.

The fundamental idea of the construction was the same as that of an English invention of the early 19th century, but it seems to have been practically used for the first time in the World War. A much greater rapidity of fire than could be obtained with this otherwise satisfactory thrower was got with the *Granatschnellwerfer*, also an Austrian invention, in which the grenades were driven by compressed air through a tube.

*Small-Arms Munitions.*—Germany's normal infantry and machine-gun ammunition was a pointed bullet which, with a muzzle velocity of 900 m/sec., was ballistically superior to the round-nosed Austro-Hungarian bullet which had a muzzle velocity of 650 m/sec. The German cartridge case was cannelured, the Austro-Hungarian rimmed.

Cartridge cases were at first made of brass, but the consumption was so great, especially as the salvage of S.A.A. cartridge cases was small compared to that of artillery empties, that steps had to be taken to find a substitute for brass. This, however, was much more difficult than in the case of artillery munitions, and it was only in the very last stages of the war that it was achieved. The cupro-nickel envelopes of the German bullet were replaced by galvanized copper for the sake of economy.

In both countries a nitrocellulose disc powder was used for the propellant charge. This ammunition has answered well. Amongst the varieties of special ammunition should be noted the German A.P. ammunition (a pre-war design), and the Austro-Hungarian XX. cartridge, likewise armour-piercing. The German bullet, instead of a lead filling, had a core of alloyed (later on unalloyed) steel embedded in lead, the two filling up the interior of the steel-casing. The Austro-Hungarian envelope bullet was similar—a conical envelope with a steel pin in the lead filling. The German bullet penetrated a 9-mm. high-quality armour plate at a distance of 400 metres, the Austrian a 7·5-mm. plate at a distance of 350 metres. Germany possessed in her 13-mm. tank bullet (similar in design to her other A.P. bullets) a weapon which was effective at a distance of 400 metres against a 21-mm. plate. The U. munition of Austria-Hungary was another special munition. This was, however, soon withdrawn. It was designed to facilitate ranging by giving on impact a good visible grey smoke. However, the incidental explosive effect brought it under the ban of international law; it was therefore soon discarded.

Later on, for anti-aircraft purposes especially, a demand was made for a tracer-bullet. Both the German and the Austrian types of tracer-bullet were capable also of wounding effect. The German type showed the trajectory by means of a backward-stretching flame visible to about 1,600 metres. Austria-Hungary made use of different types, all constructed by the Adler firm; the F.Z. shell showed the trajectory between 100 and 600 metres.

A special development of infantry tracer-bullets was the phosphorus (P) bullets; they were primarily to set on fire the petrol tanks of aeroplanes, but effect was given in the indication of the trajectory on account of which incidentally they gave good tracer effect so that the old tracer-bullet could be discarded in its favour. The P bullet was not designed solely for air warfare; for short range up to about 1,000 metres it could be fixed on wires with ordinary ammunition. It had a filling of yellow phosphorus, which was heated by the friction of the shell in the gun-barrel. At 80 metres from the muzzle it burst forth from a small opening previously closed by wax or a thin solder and ignited in the air. This phosphorus effect extended to about 400 metres. Both the indication of trajectory and the incendiary effect against fuel tanks were quite satisfactory, but against balloons its value was not conclusively proved. The difficulties of producing small-arms ammunition never assumed great proportions. It was found that the real daily demand per infantry rifle remained considerably below the peace-time estimate. The variety of weapons issued and the almost uninterrupted continuance of trench warfare in fact left less and less work for the rifle. The machine-gun alone gained—and gained enormously—in importance.

*The Production of Munitions.*—The constructive development of munitions by the Central Powers shows how they succeeded in adapting the available raw materials and in finding substitutes. The behaviour of the ammunition remained good, and even the demands imposed by the ever-changing tactical methods were able to be met. What influenced production much more strongly were the difficulties due to shortage of imported raw materials and to the unexpected volume of the demand. The peace preparations were certainly insufficient, but even if the great demand and the long duration of the war could have been foreseen, it would have been frankly impossible to cover more than a comparatively small proportion of the needs. Had every workshop in the land been given over to the requirements of war, and even an approximately sufficient supply of war stores and imported raw material been accumulated, the national wealth would have been decimated. A higher state of peace preparedness would, indeed, without overstraining the national strength, have smoothed the initial difficulties of production and eased the first munitions crisis. But all else the actual stress of war had to bring about. It alone could force everything into its service. This happened at the moment it became clear that it had become a question of a struggle for economic existence. But both States had neglected to organize the war administration in peace-time and to bring science and industry into the mobilization plan, as had been done with the railways.

In proportion as it came to be recognized that not only the industries actually producing war material, but also all the other departments of economic life, were bound up together by countless veins and formed each a limb of one corporate body, central management came into force.

This did not take place all at once, however, and at first only those regions in which there was a deficiency from the very first were covered. Nor had the Central Powers agreed upon a joint war-industrial policy; indeed, even at the end of the war complete unity of economic control had not been achieved within each State itself. Here political reasons came into play. In Austria-Hungary it was especially difficult, as the Dual Monarchy comprised two economically independent States of different structure.

Of the war needs, the greatest in extent, as also the most imperative, was that of munitions. More and more the enormous consumption made inroads into all the departments of general economic life. Its needs embraced almost all the important raw materials. The peace-time preparation of munitions had been limited to maintaining the supply in the specialized State and private factories at a level sufficient to guarantee to cover the presumed needs of the first three months' campaigning. These selected factories were also kept at a standard level as regards installation, strength of skilled workers, and supplies of raw materials. In some State works arrangements were in existence for expansion. The peace-time supplies of munitions available, calculated on the basis of the numerical demands of the General Staff, were supposed to guarantee a continued supply to the army, for a several months' campaign, until war production should become effective. Before the war 600 to 1,000 rounds were considered sufficient for light guns and somewhat less for heavy guns. These figures were not in every case fully attained, especially in Austria-Hungary. The production which was intended to be secured within the first three months was approximately equal to the actual war-material stocks.

At the beginning of the war this proposed production was immediately put in hand. In Austria-Hungary, however, the output of the peace-time demand was not fully realised, because the proposed new works for the production of shrapnel were not yet ready and the arrangements for the production of explosive (*trotyl*) had not yet been taken in hand.

Later on the monthly production in Germany reached 1,000 rounds per light gun, that in Austria-Hungary about 600 rounds, and this though meantime the number of guns had multiplied. By the beginning of 1917 the capacity of the munitions industry had in fact increased enormously—it was twenty times greater than during the first months of the war. This was due to technical science, which succeeded in procuring substitutes for the most important raw materials which were lacking.

*Central Management and Organisation of Output.*—In peace-time the production of munitions was under the different departments of the War Office. To supervise the construction and guarantee the specified quality an "*Artillerieprüfungskommission*" (A.P.K.) was attached to the Prussian War Office and the "*Technische Militärkomitee*" (T.M.K.) to the Austrian War Office, as supplementary departments. These institutions provided the technical-scientific service. The T.M.K in Vienna was, even more than the A.P.K. in Berlin, a link between the technical science and the army administration, since the manufacture of munitions was under this office itself. The supervision of the military industries, which even in peace-time represented very considerable establishments, was in Germany under the Ordnance Department (*Feldzeugmeisterei*) and in Austria-Hungary under the Inspector of Technical Artillery, who in the period just before the war was also responsible for keeping the principal war industries up to standard.

In Germany, at the beginning of the war, this organization was unchanged. The armament industry procured all its necessary raw materials itself. Industries which had no contracts to produce war material marked time. Their output was at a standstill. The most skilled portion of their workmen and officials hurried to the colours. In order to establish uniform policy and procedure German industry founded the "War Committee of German Industry." Very soon the leading industrial circles recognized the necessity of making a survey of the most important raw materials, and during the first months of the war the "Raw Materials of War Department" was established. Out of the original department composed of three collaborators a huge organization developed. Its activities consisted in regulating and supervising the economic use of raw materials necessary for the army's needs in which shortage was threatened, and it finally embraced almost all the departments of the State industry. With the long duration of the war more and more raw materials were absorbed, its sphere of activity increased, and at the end of 1917 this department, which in 1916 was attached to the War Office, employed over 2,000 people, and its subordinate "War Associations" (*Kriegsgesellschaften*) a further 5,000 employees. Of these "Raw Materials of War Associations" the first founded was "The War Metal Co." which was mainly occupied with the function of purchasing throughout the whole country all metals obtained by requisition, such as copper, zinc, etc. This was done in order to protect the small proprietors from the loss which they suffered through the lying-idle of their requisitioned goods, for which the Government did not pay until it actually used them. Subsequently the company also undertook the distribution of the metals to industry. The "Raw Materials Associations" were public utility organizations which did not work for profit. Ensuing profits were handed over to the Treasury. On the other hand losses, which were bound to occur on account of the tight hand kept on maximum prices, were met by the State. The great increase of outlay this occasioned for the State was amply compensated by the influence over prices of war munitions which it thus obtained. These companies were distinguished from other limited companies in that they were under the surveillance of departmental commissaries with a right of veto, and under the control of the War Department for raw materials.

At the outset of hostilities the War Ministries of the German States at once handed over control of the most important elements of war supply to the Prussian War Office, which transacted the business through its respective departments. The growing scale of these transactions and the recognized necessity of uniting more closely all the industrial organizations which had come into being, led in Nov. 1916 to the establishment of the "War Office" (*Kriegsamt*) within the Prussian War Ministry, to which all the departments concerned were subordinated and all the organizations and new offices extending throughout the whole German industry were attached. The establishment of the "War Office" marked the creation of a central direction, whose task it was to focus all Germany's economic activity, so as both to pool and to allocate raw materials and labour resources. As this Office was required to act in the economic, technical, and social fields alike, it could not, naturally, be constituted on a purely military basis. Suitable representation in it was given to the technicians, the commercial world, and to the labour organizations. Naturally military control dominated, since provision for the army was the chief consideration; but along with this, the "War Office" had to take over provision for the civil population.

The War Office Departments (*Kriegsamtstellen*) distributed throughout the army corps districts and the different States, and the liaison organs between all departments of war industry were subordinated to the military and technical staffs at the War Office. These departments, etc., in their more limited spheres, had the same duties as, and were the representatives of, the offices affiliated to the War Office.

A very great proportion of the organizations that were, little by little, grouped round the War Office were concerned with the production of munitions. The most important ministry in this province was the "Arms and Munition Production Ministry" (*Waffen- und Munitionsbeschaffungsamt*—"*Wumba*"). Next in point of size to the Raw Materials of War Department, it was responsible for the production of the whole army's requirements in arms and munitions. It was created in 1916 out of the departments concerned which were already in existence. Its activities comprised both the equalizing of the existing machinery and adjustment of labour in the metal industry factories. In the already mentioned *Kriegsamtstellen* and its own *Maschinenausgleichstellen* the department had its organs distributed over the country. It was the duty of the *Wumba* to supervise the fixing of prices in its own province. It worked in touch with the *Artillerieprüfungskommission* (Inspection Department).

To obtain the greatest possible standardization in manufacture, simplification of types, fixing of tolerances, definiteness in acceptance conditions and determination by the Taylor method of the working movements which gave maximal output, the *Fabrikationsbüro* (*Fabo*) was set up in Spandau and subordinated to *Wumba*. The Standards Committee of German Industry (*Normenausschuss deutscher Industrie* [*Nadi*]) instituted by the Union of German Engineers also helped towards securing standardization and economy of labour in the construction of machine parts and tools.

Next in importance to *Wumba* in the creation of raw materials and munitions was the above-mentioned "Raw Materials of War Department." It was organized in five branches dealing with the various main groups of raw materials and these were subdivided into sections. The branches most important for the activities of *Wumba* included the Chemical Section with the attached Raw Materials of War Co., War Chemicals Co. and War Phosphate Co., the Metal Sections and the Metal Statistics Section, with the Metal Allocation Office, the Metal Mobilization Office (to which the War Metal Co. mentioned earlier was attached) and lastly the Iron Section, with its attached Central Iron Co., and the Manganese Co., and the Raw Steel Allocation Office. Among the other subdivisions may here be mentioned the Coal and Mineral Oil Section.

On account of the great importance of the coal and nitrogen production the management of these departments was at an early date combined by means of the Imperial Coal Commission and the Imperial Nitrogen Commission. In 1917 these two departments were also subordinated to the War Office.

As in the beginning the needs of the army and the war industry were supplied by the various departments of the War Office, so the care of the people, at this time not an important task, devolved upon the various civil departments. With the creation of the War Department and its branches, however, active contact was naturally maintained between these departments, the ministries concerned and all authorities. The occupied territories also came under the jurisdiction of the Central Administration, but only in so far as they had to contribute to the supplies of raw material for the Hinterland.

With the building-up of this comprehensive organization Germany amply satisfied the need for an all-inclusive Central

Administration. It was only in this way that the country could hold its entire forces together. It was complete, and yet all this could have been achieved sooner and with more successful results had the organization existed in peace-time in the form of a mobilization scheme.

The Supreme Command not only assumed control over the economic management of the occupied provinces by means of the L. of C. authorities of armies and the general Governments (which set up their own administrative departments for this) but also provided through the War Office of the War Ministry for the necessary coördination between provisioning the army and the people and the military operations.

*Austria-Hungary.*—In Austria-Hungary, a few weeks after war began, the Technical Artillery Inspector was entrusted with the entire munition production; and this corresponded to the later *Wumba* in Germany. He was directly subordinate to the War Minister, and was the organ of the Government in relation to both the State and the private munition industries, the adjustment of which to war production devolved on him. In order to secure uniformity in the conduct of transactions, the munition section of the Technical Military Committee was handed over to him. Already in 1914 this department combined under one head the functions of both the German *Wumba* and the German Inspection Department in all questions relating to the production of munitions and adaptations of design to available raw materials and to production. By this means the service was simplified. Provision by the State of raw materials for munitions was concerned at this time chiefly with explosives and their basic substances, which, like all other military requirements, devolved on the appropriate departments of the joint War Ministry in Vienna, just as was the case in Germany. At the beginning of the war the Austro-Hungarian industry was in the same unsettled position as the German. Its interests were safeguarded by the existing Unions of Industry, Chambers of Commerce and such-like institutions. There was at first no new organization upon an elaborate scale.

With the recognition of the dangerous situation regarding raw materials a great extension of the central organization was made in the ministries themselves. The number of departments in the Austro-Hungarian Joint War Ministry were increased and their duties could thus be differentiated. Industry now created organizations similar to the German *Kriegsgesellschaften* in the form of Central Metal, Leather and other Societies.

The conditions in Austria-Hungary were not favourable for forming a close uniform organization which should embrace the whole country. The two separate Governments in Vienna and Budapest were theoretically independent of each other. The Joint Ministries in this case, the *K. und K. Kriegsministerium* in Vienna, could of course take measures affecting the whole kingdom, but they could only do so within certain defined limits. The Hungarian Government especially considered that it could not ensure any full subordination to the common interest. So every central organization of the administration that attempted to take over any functions formerly devolving on the separate Governments came to a deadlock half-way. The result was that the administration of certain important raw materials, especially coal and foodstuffs, was carried out for the two States separately by the two Governments. Later on, it is true, it became possible to form a central administration for iron, (non-ferrous) metals and explosives in the *K. und K. Kriegsministerium*. The administration of coal and various other stuffs remained, however, in the respective departments.

To obtain closer cohesion of all the industrial departments directly connected with the production of munitions, the various sections of the War Ministry concerned here, in the beginning of 1917, united under the jurisdiction of the *I. de T.M.*, and reorganised as a *munition department* of the War Ministry.

In addition to the production of munitions this department was, like *Wumba*, responsible for questions of machinery and supply of labour for the munition industry, and, like certain sections of the German Raw Materials of War Department, for the administration of (non-ferrous) metals and raw material for the production of explosives; coal excluded. For the administration of iron an Austrian and a Hungarian Commission were formed which possessed official authority. In January 1917 a special department in the War Ministry was created to which the Austrian Iron Committee was united. This department undertook the allocation of iron for the Hungarian half of the empire through the Hungarian Iron Committee.

The administration of coal presented great difficulties on account of the extreme dearth from which Austria-Hungary, unlike Germany, suffered. The central distribution lay principally in the hands of the civil ministries in Vienna and Budapest until the end of the war. For each half of the empire a National Coal Commission was set up, similar to the Iron Commission; these were under the respective civil ministries. In 1917 a special section was created in the *K. und K. Kriegsministerium* to deal with the State and private works hitherto dependent upon various departments of the War Ministry. It could not, however, extend its operations over such a wide field as the Iron Commission. It was in this region that purely military interests most markedly clashed with those of the Hinterland. Thus the Austro-Hungarian organization in the various major branches of munitions production was by no means as uniform as the German. This made it all the more necessary for the Supreme Command, which was entrusted with the safeguarding of the joint war interests, to interfere if these seemed endangered, so that finally in 1918 all decisions relative to coal and iron lay *de facto* in the hands of the Supreme Command. The Austro-Hungarian Supreme Command, like the German, also controlled the industrial administration of the occupied territories by means of its own organs; for example, communication with the East and with Rumania was directed by the Eastern section of the War Ministry.

*The Adaptation of Industry to War Services.*—At the time of mobilization at the outbreak of war only those works actually supplying materials of war were given work. As it became clear after the first battles that the stocks of munitions could not last the specified time, and also that the existing armament industry could not satisfy the demand, all works which were in any way suitable for the production of munitions were brought in. Thus, the admission of cast-iron shells had as its only object the employment of the more simply equipped works. Later on the munitions industry included the metal and chemical industry. In Austria-Hungary, for instance, the number of works under the jurisdiction of the Munition Department had mounted to 500, in addition to which there were a large number of smaller businesses acting as sub-contractors to the large firms. The turnover from peace to war production was not achieved without friction. The difficulties in the allotment of labour and in the rational distribution and construction of machinery were only overcome with difficulty through the intervention of the War Ministry (Munition Department).

In spite of various measures, such as the production of the cast-iron shell, delays in output were inevitable.

Subsequently, however, the industry was only hindered in developing its full working capacity by the shortage of coal and certain raw materials, especially from the winter of 1917–8 onwards, when it was difficult to obtain sufficient food for the workers. The State administration on its side had, of course, in every direction possible, simplified munition design with a view to mass-production.

*Legislation.*—Simultaneously with the last great increase in the demands made by the Army Commands upon the resources of the Central Powers (Hindenburg programme), the Auxiliary Service Law was enacted in Germany and the War Work Law in Austria-Hungary. These made it possible in 1916 to absorb the entire resources of human labour, and the production of munitions reached its maximum at this time. Already in 1914 both States had gone far in the employment of women. From 1916 on, the larger half of the personnel of the largest munition factories consisted of women.

*Raw Materials.*—The effects of the blockade had, in the nature of things, a great influence on the provision of raw

materials. The munition production was most affected, as it used by far the greatest proportion of them. The Central Powers had in no way prepared for the supply of imported raw materials; and only the rigid organization subsequently set up, the technical skill in adaptation, and above all the creations of German chemistry, rendered it at all possible for the Central Powers to continue the struggle after the first three months. This applies especially to the administration of nitrogen and the "husbanded" metals. The extension of the area administered by the Central Powers by the occupation of territory had, apart from the supply of mineral oils, only eased the situation principally in respect of foodstuffs. The production of coal and iron was subjected to the least change in relation to peace-time conditions, as these minerals were far from being purely import materials. Germany herself possessed sufficient coal and iron supplies. It is true that Austria-Hungary, whose peace-time requirements were 54 million tons—4 million imported from Germany—had a desperate struggle for the necessary quantity throughout the whole war, and the failure of supplies was bound to reduce her iron production.

It was particularly on these products that the demand rose in comparison to those of peace-time, and the output from the German mines was not such as to meet the needs of an ally in addition. The lack of coal in Austria-Hungary pressed heavily on all her war industries, but most heavily of all on her munition industry. Had the Supreme Army Command not been able to exploit the Polish coal-mines the production of munitions would have had to be reduced even in 1916. Germany's iron supplies could not everywhere in every case meet the demand for special quality. The substitution of inferior steel for high-quality kinds has already been mentioned. Similar conditions prevailed in Austria-Hungary, intensified by the coal shortage, and only the strictest economy prevented the break-down of the iron industry.

Finally in 1918 the coal shortage, due to the necessary demands of the food industry and the railways, forced such a reduction of iron and explosives production that several works had to close down, and the manufacture of products of a similar nature had to be concentrated in the best-equipped factories.

In both the Central Powers the production of the other metals—the "husbanded metals"—was inadequate. Germany's own production of copper in peace-time amounted to 2,000 tons per month; in war the expenditure rose to 15,000 per month; in Austria-Hungary the production amounted to 150 tons per month as against a war demand of 3,000 tons per month.

For this metal, as well as for nickel, lead, zinc, tin and aluminium, central administration began early. This, with the fact that, at the outbreak of war, supplies were to hand in the industry, and, later on, the requisitioning of all "husbanded" metals even to those used in household utensils, saved munition production from the breakdown that shortage of these metals would infallibly have produced. Even the church bells were utilized. Great electrolysing plants separated the pure copper. Consumption in the munition industry was opportunely reduced to a fraction through the above-mentioned use of substitutes in the designs.

The production of aluminium, of course, was substantially increased through the exploitation of the Austrian bauxite works.

At the outbreak of war the production of nitrogen threatened to be the most difficult. Both Powers had procured more than half their peace-time supplies from overseas in the form of Chile saltpetre. Nine-tenths of the whole consumption was consigned to agriculture. The yearly home production amounted in Germany to 110,000 tons free nitrogen held in ammonium sulphate from the coke and gas works, and 10,000 tons procured from the air in the form of "lime nitrogen" containing 20% nitrogen by the Caso-Frank method. The processes for obtaining nitric oxide through combustion of the air were, on account of the great demand they made upon electrical energy, dependent upon efficient water-power, and therefore never rose to great importance in Germany. Of minor importance also were the similar Austrian works at Patsch in Tirol.

The Austrian home production was 20,000 tons in peace-time from the coke and gas works, and a small quantity from a lime-nitrogen plant at Sebenico.

At the outbreak of war the situation was frankly deplorable. Both countries had just made their allocations to agriculture. Thus Germany, for example, had only 9,000 tons of nitrogen in hand in July 1914; on account of the lack of the most important raw stuffs the production of explosives seemed doubtful. Moreover, the stock of explosives themselves was extremely small—Austria, for instance, had hardly enough explosive for her 30·5 cm. mortar-shells. Apart altogether from this the lack of nitrogen manure must adversely affect the whole food production. Thus the chemical industry had before it a wide field of action and it was in this very sphere that most was accomplished. Of all the achievements of German chemistry during the war the production of nitrogen out of atmospheric air alone is of permanent importance.

The methods of obtaining nitric acid which were in operation at the beginning of the war were of small extent and by no means on an industrial footing. This, however, was put right in a short time, partly according to the Ostwald and Haber and other processes, but mainly according to the Caso-Frank method. Great plants were erected. Austria-Hungary likewise built a large plant.

Germany was able to obtain from the air by the lime-nitrogen method 110,000 tons of nitrogen yearly, and Austria-Hungary 40,000 tons; direct production by combustion of the air or by the method of Prof. Dr. Linde from liquid air was also very largely employed. The combined nitrogen production in both States was finally 2½ times the peace-time supply (imports included), and the agricultural industries as well as that of munitions could be kept supplied.

Of the remaining raw materials the most important in relation to production were glycerin, acetone and alcohol. Hitherto glycerin had been produced through the decomposition of fat stuffs. With the growing necessity of preserving these means of subsistence the employment of other methods became imperative; of these, however, only that of extraction from sugar was of importance, and sugar itself was also scarce; therefore, in the interests of economy, the use of powder rich in glycerin was restricted to the uttermost.

The acetone obtained from wood distillation (which had increased considerably, especially in Austria-Hungary) was economized by alterations in her methods of powder manufacture. The same was the case with alcohol. The attempt to produce these stuffs from cellulose certainly produced interesting results, but never attained to a vast production.

In these ways the production of munitions interfered seriously with the nation's food economy.

To increase the production of *toluol* necessary for the production of T.N.T., and obtained from the derivatives of coal-tar, the Edelmann method was applied, in which *toluol* was produced from mineral oil. In this way the chemical industry played a considerable rôle in the supply of explosives, quite apart from the importance it acquired with the coming of gas warfare.

Most of the technical achievements of the industries of the Central Powers in the war lost their significance with the termination of the war. Their great value lay in the wide experience gained in adapting everything to the imperative needs of the situation. But at any rate the setting of nitrogen extraction on an industrial footing was an achievement of permanent significance and value. (J. K.*; W. J.*)

**MUNSEY, FRANK ANDREW** (1854– ), American publisher and newspaper proprietor, was born at Mercer, Me., Aug. 21 1854. He was educated in the public schools and became a telegraph operator in Augusta, Me. In 1882 he went to New York City and established *The Golden Argosy*, a magazine for children, later changing this to *The Argosy*, a magazine for adult readers. In 1889 he founded *Munsey's Weekly*, replaced two years later by *Munsey's Magazine*, the first monthly of its class to sell for the popular price of ten cents. He also founded *The All-Story Weekly* (1904) and *The Railroad Man's Magazine*

(1906) and purchased *The Baltimore News* (1908), *The New York Press* (1912), and the New York *Sun*, both morning and evening issues (1916). He merged the *Press* in the *Sun*. In 1920 he bought from the executors of James Gordon Bennett's estate the New York *Evening Telegram* and *The New York Herald*, together with its Paris issue. He combined the *Herald* and the morning *Sun* as *The Sun and The New York Herald*, but in Oct. 1920 changed the name to *The New York Herald*, at the same time continuing the evening paper as *The Sun*, thus perpetuating intact two names famous in American journalism.

**MÜNSTERBERG, HUGO** (1863–1916), German-American psychologist (*see* 19.12), died in Cambridge, Mass., Dec. 16 1916.

Among his later publications were *American Problems from the Point of View of a Psychologist* (1910); *Psychology and Industrial Efficiency* (1912); *American Patriotism and Other Social Studies* (1913); *Psychology and Social Sanity* (1914); *The War and America* (1914); *The Peace and America* (1915); *The Photoplay: a Psychological Study* (1916) and *To-morrow: Letters to a Friend in Germany* (1916).

**MURKLAND, WILLIAM URWICK** (1842–1899), American clergyman, was born Nov. 17 1842 in Demerara, British Guiana, where his father was a Scotch missionary. When a child he moved with his parents to Petersburg, Va., and later to Richmond. In 1857 he entered Hampden-Sidney College, but on the outbreak of the Civil War he enlisted, before graduation, in the Confederate army. With one exception he was the youngest member in his command. He was captured at Laurel Hill by troops of Gen. McClellan, but was soon paroled, and returned to Hampden-Sidney College, where he graduated with first honours in 1862. Having meanwhile been exchanged, he again entered the Confederate army. After the close of the war he entered the Union Theological Seminary of Virginia where he remained three years. After his ordination as a Presbyterian minister in 1869, he was pastor of Centre Church, Cumberland co., Va. In Jan. 1870 he was called as assistant to the Franklin Street church, Baltimore, Md., and the following June was chosen pastor, which position he held until his death, May 13 1899. While detained as a young prisoner of war he had won the affection of Gen. McClellan, who later, during his residence in Baltimore, became his parishioner. At Gen. McClellan's death, Dr. Murkland took part in the funeral ceremonies. In 1890 he was a delegate to the World's Peace Congress in London; in 1893 a delegate to the Ecumenical Methodist Council at Washington; and in 1894 a delegate to the Northern General Assembly at Saratoga. Dr. Murkland was one of the prominent figures in the Presbyterian Church in the United States, and long distinguished for his ability and influence. He was an extensive traveller and a man of fine literary attainments. On June 4 1895 the 25th anniversary of Dr. Murkland's pastorate was celebrated, and many distinguished clergymen from all parts of the country together with the highest state and city officials took part. Dr. Murkland was an eloquent speaker and one of the foremost orators in the South. He was chosen orator for the state of Maryland on Maryland Day at the Cotton States' Exposition, Atlanta, Ga., in 1895.

**MURPHY, CHARLES FRANCIS** (1858– ), American politician, was born in New York City June 20 1858. He was educated in the public and parochial schools. He began work in 1876 as a street-car driver. Later with his small savings he opened a saloon, and as his business prospered became proprietor of several such establishments, in which he maintained good order. These, he declared, served as poor men's clubs. In 1892 he succeeded Edward Hagan as Tammany leader of the 18th assembly district, and from that time his political power grew rapidly. In 1897 he was appointed a member of the board of commissioners of docks and ferries in New York City, serving five years, the last as treasurer. In 1902 he succeeded Richard Croker, on the latter's retirement, as leader of Tammany Hall, a position he continued to hold for a longer period than any of his predecessors. In 1903 he secured the nomination of George B. McClellan for mayor of New York City, who was elected, and two years later re-elected. In 1906 he supported William Randolph Hearst, the unsuccessful candidate for governor of New York on the Independence League and the Democratic tickets. In 1909 he supported for mayor Judge Gaynor, who was elected. At the Democratic National Convention in 1912 he swung his followers to Champ Clark, who led on the earlier ballots. Thereupon William Jennings Bryan, who had looked with favour upon Clark, declared that he would not support him so long as he was backed by Tammany, threw his influence on the side of Woodrow Wilson and secured his nomination. The same year, as presidential elector, Murphy gave Wilson support, and in 1916 approved his renomination. He was a delegate at the Democratic National Convention in 1920, and it was in part through his influence that James M. Cox secured the nomination.

**MURPHY, FRED TOWSLEY** (1872– ), American surgeon, was born in Detroit, Mich., Oct. 23 1872. He was educated at Phillips Academy, Andover, at Yale (A.B. 1897), and the Harvard Medical School (M.D. 1901). He was assistant in anatomy at the Harvard Medical School, 1903–4; Austin teaching fellow in surgery, 1905; visiting surgeon to the clinic, 1909–11, and assistant in surgery 1910–11. From 1904 to 1908 he was assistant surgeon at the Infants Hospital, Boston, and from 1907 to 1911 surgeon to out-patients at the Massachusetts General Hospital. In 1911 he was appointed professor of surgery at the Washington University Medical School and, in 1914, chief surgeon of the Barnes Hospital and consulting surgeon of the City Hospital, St. Louis, but resigned in 1919 to become a practising surgeon in Detroit. During the World War he was director and commanding officer of Base Hospital 21 in France (1917–8), and later was director of the medical and surgical department of the American Red Cross, representing the chief surgeon of the A.E.F., with the rank of colonel. He was awarded the D.S.M.

**MURRAY, SIR ARCHIBALD JAMES** (1860– ), British general, was born April 21 1860 and joined the army in 1879. He served in Zululand in 1888, and as a staff officer and battalion commander during the S. African War, for which he received the D.S.O. A highly educated staff officer, he filled a number of important appointments during the next few years; from 1907 to 1912 he was at the War Office as director of military training, and he was promoted major-general in 1910. He then became inspector of infantry, and he was given the K.C.B. in recognition of his services. On the mobilization of the army in 1914 he was appointed chief of the general staff to the Expeditionary Force, and he held that position for the first five months of the war; after this he was employed at the War Office, and during the last three months of 1915 he was chief of the Imperial General Staff, having been promoted lieutenant-general in October. At the beginning of 1916 he was sent out to Egypt to command the field army in that country, and he shortly afterwards became commander-in-chief in that theatre of war. Under his auspices troops gradually pushed their way across the isthmus of Suez, inflicted two severe defeats upon the Turks who tried to stay their advance, and at the beginning of 1917 had gained a firm footing on the borders of Palestine. Successful operations had in the meantime been carried out against the Senussi on the western frontier, and Murray's good work was recognized by his being given the G.C.M.G. An attack delivered upon the enemy's position at Gaza at the end of March was, however, only partially successful, and when the effort was renewed three weeks later it met with discomfiture. General Allenby took over charge in the following July and Murray returned home. From 1917 to 1919 he was in command at Aldershot and he was promoted full general in the latter year.

**MURRAY, CHARLES FAIRFAX** (1849–1919), English art expert and collector, was born Sept. 30 1849. He early showed artistic talent, and became a member of the pre-Raphaelite group, being employed as a designer by the firm of William Morris & Co. He exhibited first at the Royal Academy (1867) and later at the Grosvenor Gallery (1879), but as he grew older he devoted himself to the collection of *objets d'art* of all kinds, and became a well-known connoisseur, entering the Bond Street firm of Agnew & Co. During his later years he disposed of

many of his treasures, some of the more valuable of which were presented by him to the National Gallery, while his collection of drawings by the old masters was purchased by Mr. J. Pierpont Morgan. He died at Chiswick Jan. 25 1919.

**MURRAY, GEORGE GILBERT AIMÉ** (1866– ), British classical scholar, was born at Sydney, N.S.W., Jan. 2 1866, but left Australia at the age of eleven. Educated at Merchant Taylors' school, London, and St. John's College, Oxford, he at once established his reputation as the most brilliant classical scholar of his day, winning both the Hertford and Ireland scholarships (1885), the Craven scholarship (1886), the prize for Latin verse (1886), and the Gaisford prizes for Greek verse and prose (1886–7), as well as taking first-classes in Moderations (1886) and in *Literae Humaniores* (1888). He was elected to a fellowship at New College, Oxford, in 1888, and next year to the professorship of Greek at Glasgow University, a position he held till 1899. In 1907 he was appointed regius professor of Greek at Oxford. In 1889 he had married Lady Mary Howard, daughter of the 9th Earl of Carlisle, and his sympathies were always strongly shown on the advanced Radical side in politics. He was parliamentary candidate for Oxford University at the general election of 1918 and at a by-election in 1919, but was unsuccessful. During the World War he prominently espoused the cause of the conscientious objectors, and later identified himself with efforts to ameliorate economic conditions in the enemy countries. He published a *History of Ancient Greek Literature* in 1897, but is more widely celebrated for his incomparable renderings of the plays of Euripides into English verse. Several of his versions were acted in England and America. He also published *The Rise of the Greek Epic* (1907; 2nd ed., 1911) and *Four Stages of Greek Religion* (1913). Amongst his works on other subjects are *Liberalism and the Empire* (part author, 1900); *The Foreign Policy of Sir Edward Grey* (1915); *Faith, War and Policy* (1918); *Religio Grammatici* (1918); and two early plays, *Carlyon Sahib* (1899) and *Andromache* (1900).

**MURRAY, GEORGE ROBERT MILNE** (1858–1911), British botanist, was born at Arbroath Nov. 11 1858. He was the younger brother of A. S. Murray (*see* 19.38), and was educated at Arbroath and at Strassburg University. As keeper of the department of botany at the British Museum his researches were principally devoted to algae and cryptogams, in the pursuit of which he made several voyages, notably in 1901 as scientific director to Capt. R. F. Scott's Antarctic expedition. He died at Stonehaven, Kincardineshire, Dec. 16 1911.

**MURRAY, SIR JAMES AUGUSTUS HENRY** (1837–1915), British philologist (*see* 19.40), died at Oxford July 26 1915, when the *New English Dictionary*, which he had spent 37 years of his life in editing, had reached its tenth volume. His fourth son, Oswyn (b. 1873), became permanent secretary of the British Admiralty in 1917, receiving a knighthood as K.C.B.

**MURRAY, SIR JOHN** (1841–1914), British geographer and oceanographer (*see* 19.42), was accidentally killed near Kirkliston, Scotland, March 16 1914. In conjunction with Dr. John Hjort he published in 1912 *The Depths of the Ocean*, which included the important scientific results of the expedition of the "Michael Sars" in 1910, but also formed an authoritative general statement of the position of oceanography.

**MURRAY OF ELIBANK, ALEXANDER WILLIAM CHARLES OLIPHANT MURRAY, 15th BARON** (1870–1920), British politician, known until 1912 as the Master of Elibank, was born at Elibank, Selkirk, April 12 1870, the eldest son of the first Viscount and tenth Baron Elibank (b. 1840). He was educated at Cheltenham, and in 1891 entered the Colonial Office. From 1893 to 1894 he was secretary to the governor of the Leeward Islands. In 1900 he was elected Liberal member for Midlothian, and in 1905 entered the Government as Comptroller of the Household and Scottish Liberal Whip. In 1909 he became Under-Secretary for India, and in 1910 parliamentary secretary to the Treasury and chief Liberal Whip, in which position he remained until 1912. In 1906 he retired from his Midlothian seat, and in 1910 represented Peebles and Selkirk. In this year he again stood for Midlothian, holding the seat till 1912. As Whip the Master of Elibank earned high praise for his energy and tact; but he was somewhat unfortunately mixed up with the "Marconi Scandal" in connexion with Mr. Lloyd George and Sir Rufus Isaacs, as having invested part of the Liberal Party funds in American Marconi shares in which he, with them, was speculating—a transaction hotly debated in Parliament in 1913. On his retirement from the office of Whip in 1912 he was raised to the peerage as Baron Murray of Elibank, and entered the firm of Messrs. S. Pearson & Co. as a partner, shortly afterwards proceeding to South America on business connected with negotiations for the granting of oil concessions in Ecuador, Colombia and Costa Rica. On Lord Murray's return to England in 1914 he found it necessary to make a statement in the House of Lords with reference to the part he had played in the Marconi episode, and a select committee, appointed to inquire into his action in the matter, reported that he had acted "without sufficient thought," but acquitted him of "dishonourable conduct." In 1915 Lord Murray became for a short time honorary director of recruiting for munitions work. He died at Elibank, Selkirk, Sept. 13 1920, the barony becoming extinct.

**MUSIC** (*see* 19.72).—The vast mass of new music produced between 1910 and 1921 cannot profitably be reviewed on any plan that should attempt to appraise the importance of individual composers and events. Such reviews may furnish posterity with examples of the blindness of contemporaries, and it will always be interesting to note that a Sebastian Bach may spend a lifetime making no other impression on even his most intimate circle of admirers than that of a scholar working on wholly antiquated lines; but there will never be any reason to suppose that the keenest observer of our own day will be any wiser as to what is now quietly coming into an existence which shall outlive all else that gains immediate fame.

The purport of the present article is therefore not that of a *catalogue raisonné* of modern music: its intention is to put forward certain general principles that seem to have become more clearly manifested within the decade. Any works and composers that are mentioned will be selected merely as the first convenient illustrations of these principles; and the convenience will be avowedly accidental. This method has, in the past history of criticism, always proved to give results far more interesting than those of an attempt to catalogue and estimate contemporary events and works: nor does the dearth of names and titles detract greatly from its interest. During the lifetime of Beethoven an English observer, by no means willing unreservedly to admire that already admittedly dominant and progressive master, dropped the remark that the future would reveal important musical developments in Russia. He mentioned no names, and if he had mentioned any he might not have hit upon such as would in any way add to the present interest of his prophecy. The truth is that the greatest art takes ample time before its impulses reach the main stream of historic tendency, so that the contemporary view of the main stream is naturally, and not unjustifiably, preoccupied with work that will not interest posterity; while, on the other hand, future historians will, as always hitherto, have great difficulty in finding any historic importance in the works which prove immortal.

But we are on solid ground if we fix our attention on prevalent tendencies shown by large bodies of work and of criticism, and on the conditions in which the work is produced and enjoyed. The contemporaries who thought Beethoven the greatest musician of his day deserve credit for their insight, though their reasons for their judgment were only the *Prometheus Overture* and the *Septet*. The awakening of European culture to the spirit of Greek art was mightily furthered by Lessing, though he chose in the *Laocoön* a work far from typical of the true Greek qualities which he so truly described. There are periods of artistic transition in which tendencies are too vague or too involved to be distinguished by the contemporary observer. If perhaps this was so in the beginning of the 20th century, things had become clearer by its second decade; and it was possible to draw an emphatic distinction between what is real and what is unreal in the music of the day.

It will be convenient first to deal with the unrealities. The most formidable of these arise from the unnatural conditions on which the modern musician acquires his reputation. At no period in history has an artist been able to make his living solely by his highest line of work; but the hardships of the classical artist's life were at all events not unnatural. They were mostly the effects of human nature, and not of an inflated self-consciousness among art critics. It has always been hard to struggle against a depressing prevalence of dull or vulgar tastes and pedantic conventions; but such a struggle is life, and victory in it is health. Far less certain is it that life and health can be found in the struggle for musical reputation under modern conditions; especially for reputation as a composer. The grounds on which new music is commonly criticized are no longer grounds of healthy and intelligible discussion. The critics, conscious of the proverbial persecution of genius by contemporary pedants and upholders of convention, are now unanimous in condemning all that is under suspicion of being "correct," and are desperately anxious that no *soi-disant* revolutionary tendency shall miss acclamation and that no dangerous outbreak of normality shall escape damnation. The music that is most written about and talked about is the music about which it is the easiest to say clever things. The clever things must be or seem to be intelligible to the general reader; and this means that they must not be musical facts, for musical facts are involved in musical technicalities. Yet the clever sayings must be impressive. The result is a special psychological jargon, mostly unknown to psychologists, which the general public believes to be a musical jargon. The public finds it fairly amusing, especially when the critics, having exhausted their stock of new musical discoveries and revolutions, are reduced to discussing each other. But it may be news to the public that the jargon is almost wholly unintelligible to real musicians, and nowhere more unintelligible to them than where it employs musical terms. Meanwhile real music struggles into existence, and even, occasionally, into recognition, while fashion follows the journalists, and awards fame without popularity 20 times a year to musicians of perfectly respectable character and intellect who are driven to pose as lunatics lest sanity should earn them the reputation of prigs. In such conditions it is not surprising that there is more genuine musical life in provincial districts than in the metropolitan cities. The musical life of the provinces is their own; the metropolitan public is so anxiously watching the jumping of the critical cat that even the formation of coteries is conditioned more by diplomacy than by enthusiasm. Popularity and healthily good music are driven to meet on new ground. Theatre music, apart from opera, is in Great Britain still in a state of squalor which must remain hopeless as long as British theatre-goers maintain the habit of drowning the musical *entr'actes* in talk. But the cinema produces a remarkably perfect silence in spectators, and in its not always fresh atmosphere many an excellent player finds a livelihood which he can ill afford to exchange for a good position in a permanent orchestra. The London music hall, especially since the advent of the great Russian ballet dancers, has drawn into its sphere of influence many a serious musician, among composers as well as performers; and the composers to whom it is still a strange environment may sometimes find that more than a pot-boiler impulse and technique are required of them if they are to distinguish themselves there. At all ages there have been heartsearchings as to the border lines of "legitimate" art, and the origins of the highest classical art forms have far more often been popular tendencies than critical doctrines. The health and fruitfulness of permanently valuable art demands two conditions: first, that artists shall have the inducement of a living wage for producing it; secondly, that audiences and spectators shall be accustomed to receive it so attentively as to induce the artist to refine his style. Art does not thrive in a state of public opinion and critical jargon in which nothing is allowed a right to exist except works of devastating genius, and genius itself stands less chance of recognition in such a state than in any other. A good period of art is that in which the ordinary styles are so good that the sensibilities of a child of genius are not starved or disgusted by them before he has had time to outgrow them as a genius must. Nothing good can be expected for genius or philistine from a state of art in which every style is ostentatiously paradoxical.

It is not impossible to distinguish between the fruitful and the unfruitful tendencies in contemporary music. The questions at issue are not primarily matters of taste or tradition. It may be assumed that vital art has deep foundations of taste and tradition, even if it professes to revolt from them all; but the signs of its vitality are neither in revolt nor in conformity, but simply in the variety and the coherence of the art in itself. And the variety and coherence are matters of discoverable fact. Principles which make for them are likely to be sound; principles which destroy them are, if correctly stated or imputed, certain to be unsound. We must, however, bear in mind that the creation of a work of art is an altogether different process from criticism and analysis. The craziest theory may be accepted by a composer as being his method of work, and it will do him not the slightest harm so long as it keeps his attention so poised that the depths of his mind are free to express themselves. But the same theory will be disastrous to most of his disciples, though some may share his luck with it. The classical art forms were not, in their origin and maturity, crazy theories, but shrewd generalizations from familiar experience. As that experience becomes remote the art forms lose their vitalizing expressive power. But there is more vitality in remote experience than in none at all; and a mere arbitrary contradiction of old artistic theories is, one would think, the most obvious sterilizing procedure that could be devised for future art. The procedure is seen at its worst when it is applied to some all-pervading category of music, such as harmony. Whatever may be the merits or the fecundity of the composer, we may be absolutely certain that when he explicitly promulgates a new system of harmony he is talking nonsense. A certain composer begins his career as a brilliant 20th-century Chopin, with an unmistakable power of composition in large and free form, besides a happy vein in the tiniest of preludes. In time certain harmonic mannerisms develop: the composer is also inspired to write for orchestra; his vigorous talent for composition not only stands the strain of this larger medium but remains traceable in works based each on some single artificial chord of which the original meaning is obviously a Wagnerian progression, but which the composer expounds to the gasping interviewer as the most perfect chord in music. And so the gasping interviewer goes on his way rejoicing in the possession of a profound technical mystery worthy of revelation together with the composer's theosophic doctrines and other matters of popular interest. There is no reason for doubting the composer's sincerity either in his theosophy or in his harmony. Artists are seldom also men of science, and even men of science keep some region of their minds in a state of holiday wherein they may be perfectly arbitrary and self-centred. Art originates from such regions of the mind, but it will be stifled, and those regions will be starved, unless it emerges and forages in the wide world of human life. Egocentric as is the nature of art, the confines of one personal life are not enough for sane self-development; and the personal note of the artist who retires into the recesses of his arbitrary domain will not long retain its power.

The untimely death of Scriabine left his art just at the point where it was beginning to alienate his enthusiastic supporters. Contemporary enthusiasm and hostility on theories of harmonic style may be left to the theosophists. The important fact is that Scriabine did, while he lived, produce compositions with a large flow and climax: nor do we know that his power to do so was likely to fail him. In all the chaos of modern experiment with discord and disordered rhythm, two questions alone are capable of permanently significant and truthful answers: the one concerns the composer and the other the listener. To the composer we may address Brahms's rude query, "Do you find this fun?" Of the listener we may ask, "Can you find a sufficient variety of coherent definite elements, events, qualities and forms in this art, quite irrespective of any question of novelty?" This

question must be answered with regard to all the elements of the art from the oldest to the newest, and it is one of the few sound artistic questions which concerns an artist's whole output as well as individual works; *e.g.* any one of Bach's arpeggio-preludes will show a monotony of rhythm unbroken till near the end, and will present melody only in the negative form of an avoidance of awkward intervals on the surface of the chords; but such arpeggio-preludes cannot be created by a composer who could do nothing else; the very conception of their plan belongs to all musical time and existence.

Without comparing Scriabine to Bach or even to Chopin, we may on these lines eliminate matters of taste from our estimate of works like the *Poème d'Extase* and *Prométhée*. The enthusiast is carried away, like the players and the conductor, by the climax of the *Poème d'Extase*, and is apt to declare that it attains a sonorous power never reached before in music. To which the cynic replies that Scriabine has inherited the Rimsky-Korsakoff tradition of a grammar of orchestration as accurate as that of Palestrina's vocal writing; that with this as a background he has merely to instruct the first trumpet to indulge in a street-player's *vibrato* and so to lead up to a climax which is obtained by simply allowing the full organ to drown the orchestra in the fashion of an Albert Hall performance of *The Messiah*. There never was and never will be a new sensation in the fine arts which cannot be laughed down on these lines; but real composition can never be thus laughed down, and it is real composition alone which makes a street cornet *vibrato* and an Albert Hall organ peal capable of producing new sensations. Again, these effects are obviously essentially popular; a ground, no doubt, why the description just given should be bitterly resented by many of their admirers. Yet it is just their popular quality which, rationalized by power of composition, vouches for the reality of the art. Without the power of composition a popular new sensation cannot last, even if it can make its mark at all. With power of composition everything in art must some day find wide recognition, if it escapes physical destruction; for no composer attains such power without being driven by strong human impulses. Epigrams are not enough. Human experience vividly presented never loses point.

But the chances of producing permanently living work are heavily weighted against the composer if he concerns himself only with things which he alone can understand. The Russian ballet gave abundant vital impulses to music so long as it dealt intelligibly with drama, fairy-tale, fable and life; and the young Stravinski of *L'Oiseau de Feu* found in it inspiration for music that remains brilliant and intelligible apart from the ballet. In *Petrouchka* he still makes rhythmic and instrumental sounds that faithfully follow and enhance the moods of a fascinating pantomime; but the concert-goer who, knowing nothing of the ballet, affects to be moved by the music in an orchestral concert, is little wiser than the man who would rather say he preferred the wrong end of his asparagus than admit that he did not know which was the right end. The ballet is to the composer an easier and therefore more dangerous art form than the opera; in both cases the listener will always give the music credit for all the qualities of the scenario if the composer only manages not to interfere with them. Self-deception, loss of vitality, decadence and dry-rot set in when the designers of the ballet themselves retire into the arbitrary kingdom of abstractions which they call symbolic, and which common sense calls nonsense. There is a real kingdom of nonsense, and it will have none of your owlish aesthetic solemnity about morbid twists of mind. Lewis Carroll, trained logician, leaves it to later commentators to identify his Snark with the Absolute, or with the company promoter; his and Edward Lear's wonderland of nonsense is a school of manners in the light of which any explicit social satire and many fantastic flights of [illegible] musical imagination appear almost equally convicted of [illegible] and heavy incongruity. For music, as for all arts, the [illegible] path, and that which leads even to the sublime as well as the imperishable, is a path of unselfconscious childlike enjoyment of the matter in hand, with no petulant preoccupation with the stupidity of the outsider. Erik Satie is amusing enough with his *Vraies préludes flasques pour mon chien*, his *Aperçues désagréables*, and all the rest of it; his works are announced with the challenge that, as to *les Aplatis, les Insignifiants* and other more Rabelaisian nonentities who will not enjoy them: "*qu'ils avalent leurs barbes! qu'ils se marchent sur le ventre!*"

Domenico Scarlatti, in the days of Handel, was a master of one of the most personal and eccentric *genres* of music known to history, a *genre* which, for all its confinement to one small form and one instrument, had a profound influence on all later instrumental music; and his preface is a sincere and unaffected warning to the reader to expect nothing learned, but a playful indulgence of his art. If this represents only the manners of his day, those were evidently very good manners and conducive to artistic progress and freedom.

Prominent among the eternal questions which agitate the contemporary critics of all arts at all periods is the proportion of means to ends. The modern orchestra grows easily with the demands of the modern composer, for in spite of local and temporary difficulties, it is to the interest of players that orchestras should increase as well as multiply; and the most extravagant modern composer has never yet faced the problem of designing music for which the band and chorus of a Crystal Palace Handel festival would really be to the purpose. In other words, the Handel festival exists; but the music for an organization of even half that size has never yet been composed. Here, then, is material for a real aesthetic development; and herein lies the significance of the recent vogue in Holland of the enormous works of Gustav Mahler. That great Viennese orchestral conductor died almost a generation ago, and his symphonies owe much of their recognition to the personal zeal of their apostle, the eminent conductor Mengelberg. It is improbable that the music-lovers of other countries will ever readily receive these huge volumes of naïve sentimentality and boyish grotesqueness (to say nothing of more definitely oriental traits). But the works nevertheless demonstrate at least three vital things: first, that it is still possible for a composer to pile up structures of illimitable extent in the most unsophisticated harmonic and melodic style; secondly, that, whereas taste cannot even begin to express itself without some technique, an immense amount of technique may be learnt from work which cannot be said to show any taste at all; and thirdly, that whatever may be objected to Mahler's taste and form in this direction, he undoubtedly fulfilled his set purpose of working out the pioneer aesthetic and technical principles of music designed for a thousand performers and upwards. And this is no decadent proposition. Decadence, or barbarity, is entirely on the side of the Handel festival: the performance of music on a scale for which it was never designed. The real problems of music for a thousand performers are, as Mahler perceived, problems for a severely disciplined and accurate imagination; and nothing can be further removed from the world of arbitrary artistic egoism. They are not to be mastered by the methods of that kind of extravagance which now and then displays a revulsion in some absurd economy, like Meyerbeer's old trick of thin and inadequate harmony for one voice supported insecurely by one horn and a spasmodic gurgle on a solo violoncello. Meyerbeer in his day did work that was good enough to anticipate Wagner's discoveries and bad enough to ruin Wagner's cause. Mahler has none of Meyerbeer's worldly wisdom, and in his special field there is as yet no greater and more masterly idealist.

The main stream of music still flows within the Wagner-Strauss limits and seldom requires 150 instrumental players. Arnold Schönberg's *Gurre Lieder* (a large vocal and choral cycle, the great success of which is held by his disciples to be a serious hindrance to the spread of his later gospel of musical revolution) requires a huge orchestra; but the very fact that the score often employs 50 staves proves that Schönberg is by no means imagining the aesthetics of an unprecedented scale of performance; the polyphony that requires 50 staves for its notation rather implies detail than bulk. (This, by the way, may help us to understand why the Handel festival has always had an undeniable measure of success; Handel's style is almost

massive enough to adapt itself to the monstrous organization which he never had in view. Conversely, that wonderful 16th-century monument, Tallis's 40-part motet, which remains unsurpassed for genuine complexity combined with rhetorical force, would probably prove more convincing with fewer rehearsals on 40 single voices than on a choir of 400 which could after all only give 10 voices to a part.)

The life work of Max Reger presents a strange study of artistic vitality working on methods the reverse of vitalizing. At first sight his productivity seems enormous; and since Orlando di Lasso in the 16th century we have had no other conspicuous instance of a composer who seems always able to sit down before a pile of blank music paper with a blank mind and work himself up into genuine inspiration by sheer interest in the weaving of rich musical texture. To the present young generation of German musicians Reger is the last of the classics; but there are few things in music less classical than Reger's art forms, rigidly orthodox though they seem. They are the direct result of extraordinary docility in the pupil of the most systematic musical scholar of recent times, and anyone who has groaned in spirit at the sight of one of Hugo Riemann's editions of a piece of classical music may easily recognize in Reger the traces of his teaching. Every external feature of the classical art forms is present without any trace of the classical reasons for it. Everything has been worked out from one detail to the next, without any first principles to account for the whole procedure. A facile contrapuntist, Reger writes untold numbers of fugues, all on one mechanical plan, mostly with some combination of subjects, but never a combination between subjects sufficiently contrasted to give it point. His instrumental works are for the most part cast in sonata forms; except for the incessantly modulating and chromatic style, the whole collection of works contains neither an unorthodox procedure nor the slightest reason for its orthodox procedures. Bach wrote great works for unaccompanied violin, and Reger does likewise. But he shows no sense of the principle that Bach's unaccompanied melody is its own bass; Reger's melodies cry loudly and ambiguously for harmonic support. You might as well cut out with scissors a full-face portrait of a judge in his wig and expect it to be recognizable as a silhouette. Whatever is to be learnt from Reger, it is not the meaning of classical art forms. And much is to be learnt from Reger. His texture is inevitably thick, for his rigidly systematic completeness vetoes any of that suggestiveness which is one of the secrets of the greatest art. But it is astonishingly sonorous, and, in its heavy literal-minded way, effects its purpose in the fewest possible notes, numerous though they be. Every instrument is profoundly studied and developed on the basis of its natural technique; and while the player who claims that he can read Reger at sight is probably mendacious, he will enjoy his instrument all the better for playing Reger well. Nor is this the only or the most important non-egotistic reality in Reger's work. The reality of Reger is that he is a consummate and impassioned rhetorician. His unreal art forms hinder and help him no more and no less than the alphabetical acrostic hindered and helped the poet of the *Lamentations of Jeremiah*. He extemporizes on paper, and is profoundly attentive to the nature of his instruments and to whatever text he is setting in his vocal music. In the history of art there can be no more conspicuous example of the difference between analytical theory and the practical conditions of creative work.

The only things that matter to the composer and to his posterity are the things that help or hinder him in creating his works. Posterity will not inquire whether Sebastian Bach, Granville Bantock, Richard Strauss, Busoni—whosoever you will—were reactionaries or revolutionaries, whether they followed classical forms, misunderstood them or abolished them. Nor will posterity pay any attention to the questions we so often ask as to whether such and such a composer's work had led to further developments or hindered them. This is a totally different question from that which is often confused with it, the question whether certain principles (such as a revolutionary but disciplinarian theory of harmony) do or do not interfere with a composer's capacity to write coherent and fluent works. Thus, when it is argued that Wagnerism was the cause of much mental paralysis among later musicians, the crushingly sufficient answer is that Wagnerism did not prevent Wagner himself from producing works that are among the most enormous achievements in all the records of music; and that the effect of such achievements on the sane musician is to enlarge his ideas of the range of his art. He is not obliged to cover that whole range himself; and the musician who, not being Wagner or Strauss, dooms himself to failure by working on their huge scale with inadequate resources, does not thereby show that his artistic balance would lead him to better success on a smaller scale. All great art may be accused of "leading to a blind alley" inasmuch as its achievements are always individual and unique. Yet every achievement that lives (and many live, like the works of Domenico Scarlatti and Couperin, that cannot well be called great) is a source of inspiration to right-minded artists. It is not a matter of taste; nor need it be an incitement to handle any particular art form or to imitate the style that has inspired the artist with Correggio's conviction "*Anch'io son pittore!*" It would be difficult, for instance, to name any composer whose style shows the influence of Granville Bantock; just as it is difficult to trace in his style, otherwise than by merely technical measurements, the influence of Strauss and of the schematic purity and brilliance of Russian orchestration. Yet there is probably nowhere in Europe a more radiant source of musical health. It is easiest for young composers to feel the stimulus of one who, like Bantock, has always been a keen upholder of the most modern music; nor is it anything but a healthy sign of the times that those who still find their interest in classical resources must plough a lonely furrow. They may contentedly do so, like Sebastian Bach, if like him they also maintain a hopeful interest in the present and future of the new movements which they do not feel drawn to imitate in their own work.

Another striking example of artistic vitality commands attention in the work of Gustav Holst, an English composer whose interest in oriental subjects is (like Bantock's) no whim for *chinoiseries* but a true expression of the nostalgia of the West. In every direction his work is masterly, independent, and indisputably real. *Savitri* is an oriental opera written with the slenderest of instrumental resources and with much singing that is not only unaccompanied but unharmonized. Holst has also produced beautiful songs for the strange combination of a solo voice accompanied only by a violin. At the other end of the scale we have his orchestral work *The Planets*, in which he shows his full musical freedom. Probably the work in which his design most accurately and tersely fills its space is his setting of the sublime ancient Byzantine *Hymn of Jesus*. Here the music seems indistinguishable from the text; and its primitive and drastic harmonic logic, which technically could not have been written before the time of Debussy and Ravel, is no more suggestive of the fashions of to-day, or of any day, than the awe-inspiring Eucharistic text which reverberates through it. No modern music is more utterly unsuggestive of outward and technical resemblance to the classics, and none rests on deeper foundations of musical scholarship.

Among the most significant signs of life in English music we must mention Rutland Boughton's remarkable musical festivals at Glastonbury, where (until interrupted by the World War) he produced English opera on a small scale, ranging from Purcell to his own and other contemporary works.

It is easy to ask what effect the World War has produced on music. The wisest answer is evasive. Few, if any, of the works written avowedly to commemorate the war can possibly succeed in meaning what they say or saying what they mean. And of the losses to music, who shall discriminate between the talents that had been given time just to reveal their promise and those that were cut off yet sooner? What now of Russia, where in 1921 world-famous composers were living in starvation without even paper to write on? If any musical work is destined to impress posterity as a noble expression and reaction of the World War, the choice, strange as it may seem, might most desirably fall on

Richard Strauss's *Die Frau ohne Schatten*. His *Alpen-sinfonie*, which, designed before the war, appeared in 1915, was a great disappointment, amiably commonplace in "programme" and sentiment, and hardly more than automatic in its characteristic "road-hog" technique. As to *Die Frau ohne Schatten*, Strauss's style is no longer a new sensation and it cannot be easily proved to be less automatic here than in the *Alpen-sinfonie*. The intention of the work as a whole must be ascribed to the poet Hofmannsthal; and so we still seem to leave room for the argument that Strauss, like other adroit opera-writers, has little more to do than to avoid hampering the poetry and action. But it is at least equally possible to assert roundly that Strauss is here at the height of his power and inspiration; that his mastery of composition and texture has never been seriously in dispute, whatever exception may have been taken to the extremes and licences of his style; and that, if the poet's intention is noble, the composer has made its realization vivid as no one else could imagine. The intention of the work is such as can be carped at only at the peril of the critic's rightness of thought. One of the real difficulties in the understanding of Wagner's art was, and still is, that whereas his mature music shows his strength, the ethics of his poetry often shows his weakness. For one person who appreciates the tragic nobility which drove Tristan and Isolde to drink what they took for a death potion, there are a dozen who get and mean to get from the whole music-drama nothing better than a view of life as the irresponsible intoxication of a *Liebestrank*. This is not fair to Wagner, yet it is largely his fault. But if the world will only allow itself to be emotionally stirred to the same extent by Strauss's *Die Frau ohne Schatten*, then a great musical work will have played a historic part in restoring the health of the nations. From the twilight of 19th-century and recent erotic art, and from its always selfish and sometimes abnormal sexual preoccupations, *Die Frau ohne Schatten* breaks away, and its plea for love is nature's plea for life. Musically it is, more copiously than any of Strauss's former works, an occasion for beauty; as a dramatic spectacle it is a gorgeous fantastic pantomime, of which the allegorical meaning leaves it hardly less childlike than *Die Zauberflöte*, which it in some points intentionally resembles. It is altogether a noble and heroic work, unassailable by any cavil that does not condemn itself as ignoble.

In the early summer of 1921 a new kind of double keyboard for pianofortes, invented by the eminent Hungarian composer Emanuel Móor, and manufactured by Messrs. Schmitt-Flohr of Berne, was demonstrated in Berne to large audiences. There is no reasonable doubt that it must soon render the ordinary pianoforte as obsolete as the harpsichord, and that it is by far the most important invention in musical instruments since the pianoforte itself. The principle is simple and might just as well have been discovered when the pianoforte was first invented: in which case Mozart's pianoforte-technique would have begun considerably beyond the point where Beethoven's now leaves off. Two manuals are placed, the one so slightly raised above the other that a perfect *legato* in rapid passages is obtainable between them by one hand. The second manual is an octave higher than the first. Thus the normal stretch of one hand is two octaves instead of one; and with the cultivation of a new set of movements of the hand, backwards and forwards as well as laterally, the possibilities of pianoforte-writing already seem limited only by pure musical aesthetics. But this is not all; the two manuals can be coupled together by a pedal, so that the instrument possesses much of the property of the organ and also of the harpsichord, in the power of doubling a whole mass of harmony or any part thereof in "four-foot tone." The restoration of harpsichord effects is completed by a lever which operates a kind of sordine, producing a surprisingly good representation of harpsichord tone.

The invention is conservative as well as revolutionary. The pianoforte does grave injustice to many aspects of harpsichord music, but this "Duplex Coupler" system leaves purists at liberty to play classical pianoforte music without even altering a fingering; they have but to refrain from using the back keyboard and the couplers. There is a vast new technique awaiting long study and exploration; but the merest rudiments of it produce astonishing results in a short time, for the pianist who gave the first public demonstration did so within six days of setting eyes on the instrument. It cannot fail to have an enormous effect on the future study of music. Doubtless, it will develop its own vices as well as resources, but it begins by depriving pianists of occasion for four-fifths of their worst habits, and sets a premium upon a Bach-like and Mozart-like cultivation of polyphonic *cantabile*. Many composers use the pianoforte in the act of composition far more than they are willing to admit. They know it to be a bad habit because it tends to cramp their invention in two directions: it confines phrasing to the obvious sequences that muscular memory best grasps, and it confines part-writing to the compass and convenience of the hands. The second limitation is now removed, and those composers who suffer from "pianistic" habits will speedily show greater freedom in their writing for other instruments and for orchestra. Thus there is no region of music which will remain uninfluenced by Emanuel Móor's Duplex-Coupler pianoforte, and this instrument will be a very important source of interest and inspiration in the music of the future. (D. F. T.)

**MUSTAPHA KEMAL** (1879– ), Turkish pasha, was born of humble parents at Salonika. By his great energy and the political connexions that he formed as a leader of the Young Turks he rose to military eminence in the Turkish service. In spite of slight physique and a dissolute life, his reckless courage and ambition brought him into prominence in the war against the Italians in Tripoli; he was made aide-de-camp to Wahid-ed-din, afterwards the Sultan Mohammed VI. In Aug. 1915, as commandant of the Turkish detachments in Anaforta Bay (Gallipoli peninsula), he gave proof of his ability, and enjoyed the especial confidence of the German commander-in-chief, Gen. Liman von Sanders. In 1917 he commanded the III. Caucasian Army. In the winter of that year, after coming into violent conflict with Gen. von Falkenhayn, he resigned. When, however, a little later, Falkenhayn was recalled from Palestine after his complete failure there, Mustapha Kemal held a high command under Liman Pasha, and after the conquest of Palestine Mustapha Kemal took over from Liman Pasha in Adana the remnants of the Turkish forces. Out of these and a number of volunteers he organized the Nationalist army. He put himself at the head of the Nationalist Government, and won through in his strenuous campaign against the legal Government in Constantinople. He afterwards ruled with almost absolute power in Angora, and thence conducted the counter-offensive of the Turkish Nationalists against the Greeks when the latter, in 1921, made their ineffectual forward movement in Asia Minor, which was brought to a standstill in the autumn. A later counter-offensive in 1922 was eminently successful.

**MUTSU HITO** (1852–1912), MIKADO, or EMPEROR, OF JAPAN (*see* 19.100), was represented in 1911 at the coronation of King George V. by H. I. H. Prince Higashi Fushimi, both Admi. Togo and Gen. Nogi being on the imperial staff. A year later the Emperor was stricken down by illness, and succumbed to it on July 30 1912. The simplicity of the Emperor's personal life, and the concern he had always displayed for the welfare of his subjects, had endeared him to his people. The obsequies took place on Sept. 13 and 14, with Shinto rites, at Moyayama, near Kioto, and, in addition to the presence of special ambassadors from the foreign Powers, a guard of honour from the British navy testified to the alliance between the two island empires of East and West. A profoundly touching impression was created throughout the whole world by the suicide of Gen. Count Nogi and of the Countess Nogi, at the moment that the body of the Emperor was leaving the palace.

NAMUR (*see* 19.159*).—In 1914 the pop. numbered 32,453. The manufacture of glass and glassware had been recently established. An athletic sports ground was laid out and a fine open-air theatre built before the World War in the park on the citadel hill. The Germans entered Namur on the evening of Aug. 23 1914, deliberately set fire to the town in five places, and gave way to looting. All the houses in the Place d'Armes and its vicinity were burned and the Hôtel de Ville destroyed; and between Aug. 23 and 25, 75 civilians were shot without motive. A war contribution of 50,000,000 fr. was levied and Namur became a cavalry headquarters and base.

### The Siege of 1914

In the defence scheme of Belgium, Namur, with Liége and the small intermediate fort of Huy, had the rôle of barring the line of the Meuse against attack from the East. It had in addition to secure the left flank of the field army in case of an invasion by the French, and, further, as against eastern invasion, it supported the right flank of an army disposed on the line of the Gelte to resist an enemy who might have mastered Liége. The last named was the case which actually arose in Aug. 1914 and led to the attempt being made to hold Namur in spite of the disheartening experience of the power of the German heavy artillery which the Belgians had just suffered at Liége.

The permanent defences of Namur at the outbreak of war in 1914 consisted in a ring of nine forts catalogued here in clockwise, or E.—S.—W.—N., order—three (Maizeret, Andoy, Dave) in the great bend of the Meuse E. of the towns, two (St. Héribert and Malonne) in the angle of the Meuse and Sambre S. of it; two (Suarlée and Emines) on the open N.W. front astride the Gembloux road; two on the N.E. front covering the Tirlemont road (Fort Cognelée) and the St. Frond road (Fort Marchouelette) respectively. In each of the intervals between fort and fort, infantry and field artillery positions were constructed on mobilization, and included in the defence system of each interval were two, three or four infantry redoubts. The principal line of defence followed in general the imaginary perimeter of the fort-ring, but in the E., conforming to the requirements of the broken ground, the line of trenches redoubts was drawn back, notably near Fort Maizeret, where it passed at a distance of a mile behind the fort, and also at Fort St. Héribert on the S. front.

Although it was a ring-fortress, of Brialmont's design, similar in all respect to Liége from the technical point of view, the tactics of both attack and defence were very different from those employed in the earlier siege. Not being exposed to surprise, the garrison had ample time to protect the intervals of the forts with trenches, redoubts and wire, as well as to clear the foreground. Moreover, at the time of the attack, Namur was, so to speak, a strong salient point on the general line of battle of the field armies and not an isolated stronghold. To right and left of it, the German offensive was meeting, or about to meet, the French IV. and V. Armies and the British Expeditionary Force. The attack was carried out by those German corps which in the line of battle lay opposite to the fortress, and not by a special force. It was carried out not in two stages as that of Liége had been—*coup de main* on the intervals followed by methodical battering of the forts—but in one effort, the infantry attack and the siege artillery bombardment being simultaneous and interdependent. It is therefore, in some respects, the tactical prototype of the Verdun struggle of 1916, with the two important differences that in Aug. 1914 troops had not learned the strength of a trench-network or become familiar with the effects of super-heavy artillery, and that at Verdun the artillery had been removed from the forts, which were treated purely as infantry strongpoints.

The garrison of Namur, under Lt.-General Michel, consisted of the 4th Div. (3 mixed bdes.), four fortress infantry regiments, the garrison artillery and engineers appropriate, and various small units, and numbered about 27,000 combatants, reinforced during the defence by one French infantry regiment.

The attacking army consisted of four divs. (later five) (Guard Res. Corps, half VII. Res. Corps, XI. Corps) drawn from the inner wings of the II. and III. Armies, formed as a temporary Army Group under General von Gallwitz, and provided with a siege train which included one battery of 42-cm. and 4 batteries of Austrian 30·5-cm. howitzers as well as 21-cm. howitzers and medium guns.

During the defence of Liége, the Belgian army was concentrated along the Gelte line, facing E., waiting for the arrival of French and British forces N. of the Sambre. In this position Namur covered its right and Antwerp its left. But when the Germans had made good the passage through Liége and deployed their I. and II. Armies facing the Gelte, they manœuvred to cut off the Belgians from Antwerp, their main base, and the King therefore fell back gradually in that direction, giving up contact with Namur. At the same time the French V. Army was assembling in the angle of the Sambre and the Meuse, and thus the Belgian fortress came to occupy the centre of the French northern battle-line. The Germans, meantime, leaving a containing force in front of the positions around Antwerp, initiated the great wheel of their right wing which was to envelop the French or British left. The pivot of this wheel was not, however, Namur but Thionville, and thus Namur had to be tackled by open force during the progress of the wheel. During Aug. 18–19 the left of the German II. Army advanced slowly on Namur from the direction of Huy, clearing out of the woods and villages the very active outpost forces of the garrisons, while the right of the III. Army was still far back in the Ardennes. On Aug. 20 the union of the two portions of von Gallwitz's forces was completed and the XI. Corps stood with its right flank on the Meuse, west of Audenne, and its left about Florée. The 1st Guard Res. Div., which had hitherto followed the S. bank of the Meuse, had been switched to the N. bank when the XI. Corps became available, and after a fierce fight with the inhabitants of Audenne stood behind the sister div. (3rd Guard Div.) a few kilometres back of Audenne and E. of Hingeon. The right of the Guard Res. Corps, therefore, instead of reaching the region of Hemptinne, extended (evening Aug. 20) no further north than Pontillas.

This rightward movement, though its immediate cause was the arrival of the XI. Corps, marked the beginning of a change of plan. The original intention was to press the attack home on the E. and S.E. points of Namur. On Aug. 20 this was changed, owing ostensibly to the discovery that siege operations were extremely difficult in the woods and deep valleys of the S.E. front, but really to the arrival of large French forces on the Sambre which constituted a threat to von Gallwitz's exposed right wing, the weight of the attack being shifted to the N.E. and N. front. During Aug. 21, while the 3rd Guard Div. with one bde. of the 1st Guard Res. Div. continued to advance in the region of Hingeon and Vezin, and the rest of the 1st Guard Res. Div. completed its flank march to Hemptinne, the 38th Div. of the XI. Corps was taken out of the line and formed in reserve at and S. of Audenne. Thus there were two divs. N. and one div. S. of the river with one in reserve on the Meuse itself. Of the siege artillery, however, a considerable portion was and remained S. of the Meuse, for in order to avoid the delays that had been so serious at Liége, von Gallwitz had emplaced his heavy and super-heavy pieces at the very outset of the attack, before the change of plan. Thus the main attack, N. of the river, took the form of an "abbreviated siege" *à la* Sauer,—full-force assault on the intervals combined with smothering and ruin of the forts—while the operation S. of it rather resembled the second phase of Liége, viz. methodical ruin of the forts in succession by heavy artillery under cover of an infantry screen.

During Aug. 22, while heavy fighting continued in the foreground of Fort Marchouelette, the rightward shift was com-

* *These figures indicate the volume and page number of the previous article.*

pleted by bringing the 38th Div. and the 1st Guard Res. Div. (somewhat intermingled) into the N.E. area, opposite forts Cognelée and Marchouelette. At the same time the 3rd Guard Div. condensed as much force as possible on its right, opposite the latter fort. A div. (the 14th Res. Div.) arriving from the II. Army was disposed on the N.W. side, to threaten Forts Emines and Suarlée. Thus 2½ divs. out of five were placed on the front selected for assault, which was little more than 3 m. wide. No general reserves were kept back. The artillery was in position and opened fire in the morning, except some of the super-heavy batteries which were not ready till the afternoon. On the morning of Aug. 23 the assault was to be made. According to the German official account, there were many misgivings, for it was evident progress had hitherto been slow, the intervals were known to be well prepared and manned, and it was thought that the time allowed for crushing the forts was too short.

Von Gallwitz, however, persisted in his decision and in reality the defence was on the point of collapse. Fort Marchouelette, bombarded by 21-cm. howitzers from 10 A.M. on Aug. 21 and by 42-cm. howitzers from the morning of Aug. 22, was almost incapable of resistance, and collapsed in ruin, with two-thirds of the garrison dead, at 1:40 P.M. on Aug. 23. Fort Cognelée, under bombardment by the Austrian 30·5-cm. howitzers on the previous evening, had given in some time before. But here the battle had already passed inside the fort ring. The unsuccessful fighting and notably a counter-attack in the evening of Aug. 22 had exhausted the defenders of the interval trenches and redoubts, many of which were lost before dawn of Aug. 23. To sustain the battle, moreover, Lt.-General Michel had expended practically all his reserves.

Thus the German assault of Aug. 23, delivered with very heavy forces and accompanied by an intensive bombardment of the forts by super-heavy and of the intermediate positions by heavy field artillery, was completely successful. The break occurred near Fort Cognelée where the French contingent began to retreat about 10:30 A.M. One by one, from left to right, the fighting groups of this front gave way; the rightmost, on the Meuse, being the last to conform, were mostly cut off and forced to surrender, though they had had no difficulty in maintaining the frontal defence against the weakened left of the 3rd Guard Div. The Emines–Suarlée sector troops, turned on their right after the break-through near Cognelée, withdrew in succession from right to left towards the Sambre bridge at Bauce, but the forts, intact, prevented any attempt to break through on the part of the newly arrived 14th Res. Div. outside this front and Fort Emines inflicted losses on the Germans as they pursued southward from Cognelée. Meanwhile, the bombardment on the E. front, where, as has been noted, a large part of the German siege artillery still remained, had destroyed Fort Maizeret before nightfall of Aug. 22, though the infantry in front did not realize the fact till 2 P.M. on Aug. 23, long after it had been evacuated. The artillery then turned upon Fort Andoy, but this fort repulsed a premature attack of the weak infantry forces in its front, and was unconquered at nightfall. Nevertheless, the collapse of the interval defence N. of them caused the commander of the E. sector to withdraw from his line of redoubts from about 12:30 P.M. and by 7:30 P.M. all troops except the garrisons of Forts Andoy and Dave had taken refuge in the southern sector, W. of the upper Meuse.

Once through the main line of defence von Gallwitz's attack-mass met only disconnected resistances on its way to Namur, and the Germans entered the town at 7 P.M. The Sambre bridges were however blown up, and the rest of the evening had to be given up to reorganization of the much mixed-up units which had converged on the narrow front Bouge–Namur–Pont de Bauce. On the morning of Aug. 24 von Gallwitz prepared to reduce the remaining forts; the 38th Div. by way of Bauce was to attack Fort Malonne, the 33rd Div. to continue its attack from E. to W. against Forts Andoy and Dave, and the 1st Guard Res. Div. from Namur, the 14th Res. Div. outside, and the siege artillery which had reduced Marchouelette and Cognelée were to capture Forts Emines and Suarlée. The 3rd Guard Div. remained in Namur, ready to support any of these three attacks as required, and to overawe the inhabitants, with whom there was sporadic fighting followed by house-burnings.

Lt.-General Michel, meantime, after collecting the disordered forces coming in from N.N.W. and E. in the area between the Sambre and Fort St. Héribert, had decided that it was impossible to remain there, the more so as on the one flank the French V. Army on the Sambre was already beginning to fall back, and on the other a German advance on Dinant was hourly threatened. The retreat of the Namur garrison began on the same night; it was not possible to carry it out according to a scheme, and each column had, in the main, to fend for itself. Part of the retreating forces narrowly escaped capture by troops of the German II. Army which were advancing in pursuit of the French. Finally, however, the remnant of the Belgian 4th Div. was reassembled and sent by train to Havre and thence by sea to rejoin the army at Antwerp. The total number of prisoners taken by the Germans was about 6,700.

The Germans had still to reduce the remaining six forts which barred the roads and railways necessary for the further advance of the German II. Army. This task was promptly taken in hand Aug. 24. On that day Emines and Suarlée, hitherto immune, were heavily bombarded, while from front and rear the infantry closed up on them. South of the Sambre, however, Fort Malonne fell without resistance to the bold summons of a Prussian Guard lieutenant with four men, and Fort St. Héribert capitulated after a short bombardment by field and medium calibres. Against Fort Andoy, the bombardment of Aug. 23 continued till the fort was surrendered, a heap of ruins, at 11 A.M. on Aug. 24. On Aug. 25 at 3 P.M. the last fort on the E. side, Dave, surrendered to bombardment by 21-cm. and medium artillery.

To the reduction of Emines and Suarlée, the whole power of the 42-cm. and 30·5-cm. artillery N. of the Meuse was devoted on the morning of Aug. 25. In a few hours their cupolas were pierced or jammed and their concrete galleries and chambers blown in, and both surrendered about 4 P.M. (C. F. A.)

**NANSEN, FRIDTJOF** (1861– ), Norwegian scientist, explorer and statesman (*see* 19.162), carried out as professor of oceanography in Christiania University much important work on the variation of oceanic currents and the water of the Norwegian Sea (*see* OCEANOGRAPHY). During the World War he did much relief work, and interested himself with admirable results in the welfare of prisoners of war. His work was recognized by his appointment as High Commissioner of the League of Nations for the repatriation of prisoners of war. On the institution of schemes for the relief of the starving Russian populace in 1921, he was appointed one of the commissioners in charge of the project. His more recent works include *Northern Mists* (1911) and *Through Siberia* (1914).

**NAOROJI, DADABHAI** (1825–1917), Indian politician (*see* 19.167), died at Versova, near Bombay, June 30 1917. He had been indefatigable in proclaiming the long since discredited doctrine that the British connexion with India, with its concomitant of home charges without economic equivalent, constituted a drain upon India which kept her poor; and this, with the demand for increased Indian agency, was the keynote of his collection of writings and speeches *Poverty and Un-British Rule in India* (1901). While he kept firmly to constitutional agitation, condemning violent methods when they arose, his constant assertions of "the drain" and that Great Britain was breaking her pledges did much to generate beliefs from which sprang the extremist school of Indian political thought. In the moral strength given by the simplicity and purity of his manner of life, and his unselfish inflexibility of patriotic aim, rather than in exceptional intellectual or constructive power, lay the secret of the unrivalled position "the Grand Old Man of India," as he was called for a generation, held in the affections of his fellow countrymen of all classes. He finally left England early in 1907, and the last 10 years of his life were spent in retirement, from which he emerged only to receive the hon. LL.D of Bombay University in 1916.

**NAQUET, ALFRED JOSEPH** (1834–1916), French chemist and politician (*see* 19.236), died in Paris March 11 1916.

**NARES, SIR GEORGE STRONG** (1831–1915), English Arctic explorer (*see* 19.246). In later life he acted as one of the conservators of the river Mersey. He died at Surbiton Jan. 15 1915.

**NAREW, BATTLES OF THE** (1915).—The lower course of the river Narew, with, on the one hand, its affluent the Bobr, and, on the other, the line of the lower Bug into which it runs, forms, against an invasion of Poland from East Prussia, a barrier which played a considerable rôle in the eastern front campaigns of the World War. This barrier was reinforced by bridgehead fortresses at Osowiec on the Bobr, Lomzha and Rozhan on the Narew, and Zegrze and Novogeorgievsk (or Modlin) on the Bug—the last named, a ring-fortress, bestriding also the Vistula and the Wkra and standing in close relation to the fortress of Warsaw. The course of the Bobr–Narew–Bug water-line is marked throughout by marshes, which, sometimes on one side of the water and sometimes on the other, but generally on both, vary in width from half a mile to 2 m. and at certain points broaden out into wooded marsh-basins, 6–10 m. in width or breadth.

Between this barrier and the S. frontier of East Prussia, inside which the western Masurian lakes offer lines of defence against Russian invasion, there were constant advances and retreats of each side during the first campaigns of the World War. The first Russian advance culminated in the disaster of Tannenberg (*see* MASURIA, BATTLES IN), and was followed by a gradual advance of minor German forces to the region of Wloclawek on the Vistula, Plonsk, Ciechanow, Przasnysz and Chorzelle, in conjunction with the main campaigns in West Poland. Then, early in 1915, the Russians prepared a great offensive, which was to take the same general direction as that of Aug. 1914. The Germans, however, by seizing the initiative early in Feb. delayed the development of this offensive. Their main effort, the winter battle of Masuria, was made on the E. front of East Prussia, while the S. front was guarded by an army group under General von Gallwitz, who carried out his task offensively, driving southward into the area N. of the Narew, where the Russians were assembling. This move led to very severe fighting, notably at Przasnysz; and Gallwitz, though reinforced by degrees, maintained himself with great difficulty against the onset of the Russian XII. Army. Then, gradually, the battle became stabilized, and, the great Austro-German offensive in West Galicia having from May 1 transferred the centre of gravity to the other wing, the country between the Narew and the western Masurian lakes was quiet for two months. It is a country of poor communications, sandy soil, low elevations, and numerous N.–S. streams—affluents of the Bobr, Narew or Bug—which occasionally turn into the E.–W. direction and offer partial lines of defence to either side. It is wooded, heavily so in its eastern portion, where the Narew and the Masurian lake zones converge.

Thus the Narew–Masuria battle-field, as it may be called, is triangular in shape, limited on the E. by the woods of the Pissek (or Pissa) region, lying between the Prussian Lake Spirding and the Russian fortress of Lomsha, on the S. and S.E. by the course of the lower Narew and lower Bug, and on the W. practically by the river Wkra and the fortress of Novogeorgievsk. Across this battle-field, in July 1915, the Russians held a front line roughly parallel to the Prussian frontier and therefore oblique to the Narew. It ran from the outlying defences of Lomsha on the right, by Cierlozy and Lipniki to Berdowelonki on the river Omulew, and thence by Cierpienta and Jednorozec on the Orzyc to Mchowko in front of Przasnysz; thence it continued a short distance westward to Grudusk, and at that point turned southwestward to the Vistula. This line was duplicated by rear defences, notably the "Bogate position" between Ciechanow and Krasnosielc; a switch-line connected Ciechanow and Przasnysz, another the centre of the Bogate position, and yet another the right of that position with the bridgehead lines of Pultusk. On the Narew itself, Lomzha, Rozhan and Pultusk (which already possessed works in peace) had been developed into large bridgeheads, and the modern permanent works at Zegrze on the Bug had been extended to include Serock at the Bug–Narew confluence. Novogeorgievsk, already a great ring-fortress in peace, had been surrounded by two enveloping rings of outer defences.

When, after the break-through of the Russian positions at Gorlice–Tarnow, Radymno and Grodek (*see* DUNAJEC-SAN, BATTLES OF THE), Mackensen's armies swung northward to reach the rear of their opponents in Poland by way of the upper Bug, a similar blow upon the N. side was planned by Falkenhayn for the armies under Hindenburg. As to the direction of this blow, there was acute controversy between Falkenhayn on the one hand and Hindenburg and Ludendorff on the other (*see* EASTERN EUROPEAN FRONT CAMPAIGNS, Part III.), and it was only by the pure assertion of authority that Falkenhayn imposed upon them the offensive on the Narew which is here described. Hindenburg and Ludendorff objected that, against so strong a series of positions as those of Przasnysz, Bogate and the Narew, there was no hope of such rapid progress as would enable Gallwitz to come in upon the rear of the Russians in West Poland in time to cut them off. The other arguments for and against a Narew offensive were of a more purely strategic character, and are not here considered, but it must be noted that each of these arguments, taken in itself, was proved by the sequel to be well founded. The view taken by Falkenhayn and that of Hindenburg and Ludendorff as to their relative importance in the *ensemble* differed fundamentally, Ludendorff's ideal being the cutting-off of the entire Russian army by the pincers closing from N.E. and S.E. on its rear, whereas Falkenhayn's object was more limited—to deliver a blow that would relieve pressure on Mackensen's front and so enable him to penetrate to Brest Litovsk from the south. To achieve this object, the offensive must, according to Falkenhayn, threaten the rear of the Russian positions in Poland at the earliest possible moment, and, therefore, by the nearest and shortest line of operations, since Mackensen was practically unable to start his movement along the upper Bug till the strength of the Russians in front of him had been materially reduced (*see* BREST LITOVSK, BATTLES ROUND).

Thus, although the record of Gallwitz's offensive on the Narew is one of slow frontal advances which aimed at the Russian communications but never reached them till the retreating enemy had passed on—although finally he could only join the German frontal armies in the general pursuit—the battles described below must be considered as successful or otherwise in relation to the object for which they were really fought. In the last analysis, they were, like the battles of the British army in Flanders in 1917, a relief-offensive, which in securing their object might, if fortune so willed it, secure other results as well.

*Forces and Positions.*—The portion of the front selected for attack by Gallwitz was that between the river Orzyc and the village of Grudok, in the middle of which lay Przasnysz; and the date chosen for the attack was July 12, afterwards changed to July 13. As already mentioned, the original cordon of troops along the S. front of East Prussia had grown by reinforcements during the spring battles in the Przasnysz region to the strength of an "army group," and for the July offensives it was given additional forces, though it was not till later that the title XII. Army was assigned to it. It consisted, from left (river Skwa) to right (river Vistula), of the I., XIII., XVII., XI., XVII. Res. and Dickhuth's Corps. Of these, the XIII., XVII., and XI. lay opposite the selected front with their divisions thus disposed. On the XIII. Corps front were the 4th Guard, the 3rd and the 26th Divs., with, on the left astride the Orzyc, a liaison detachment of the I. Corps under von Falk. On the XVII. Corps front, which extended from the Murawka stream to opposite Pavlovo-Koscienie, were the 36th Div.—its left facing Przasnysz—and the 1st Guard Res. Division. On that of the XI. Corps, which ran from the Russian salient N. of Pavlovo-Koscienie to Grudusk, the 86th Div. (of Landwehr and Ersatz units) and the 38th Division. From Grudusk southwestward, astride the Mlawa–Ciechanow–Novogeorgievsk railway, lay the 14th Landwehr Div. and 85th (Landwehr units) of the XVII. Res. Corps. In army reserve were the 35th Div., Pfeil's Bde. of the 14th Landwehr Div. and (after the first day) the 50th Res. Div.; later the 83rd Div., Menges's Div. and the 54th Div. were placed at Gallwitz's disposal by Hindenburg.

In the attack sector between Orzyc river and Grudusk the

Russians had at the outset only three divisions, and Mackensen's earlier battles had shown that they were probably ill equipped with munitions. Nevertheless, owing to the strength of the positions, the battle was planned purely as a "trench warfare" offensive, with technical equipment on the full scale regarded in 1915 as adequate.

*Przasnysz (July 13–14).*—On July 13, after a bombardment of 3½ to 6 hours, according to the circumstances of each sector, the infantry attacks of the XI., XIII. and XVII. German Corps were launched on either side of Przasnysz, on a total active frontage of about 20 miles. The defences in front of Przasnysz itself were threatened, but not attacked in earnest, by the 36th Div., the intention being to break through on both sides of the strongly fortified point and reduce it by envelopment. Everywhere the first line of the defence was carried. On the right of the XVII. Corps front the 1st Guard Res. Div., and on the right of the XI. the 38th Div., attacking the faces of a small salient, cleared the way for the central division, the 86th repeating the same tactics at the second line. East of the Murawka the centre of the XIII. Corps (3rd Div.), after carrying the first line, was, unlike the XI. and XVII. Corps, met by a series of fierce though small counter-attacks, which hampered progress all along the line.

In the afternoon the German effort received a fresh impulse. On the XVII. Corps front the hitherto reserved 35th Div. was put in on the left of the 1st Guard Res. Div., and this increment not only enabled the XI. and XVII. Corps to break through the right and the left of the Russian third line between Lysakowo and Choinowko but also to prepare to invest Przasnysz on the S.W. side. In the night of July 13–14 the Russians evacuated the few trench-elements that they still held and retired on the Przasnysz–Ciechanow switch-line. To the E. of the Murawka, the whole XIII. Corps front took up the offensive initiated by the 3rd Div., but progress remained slow, and at night only the first line and the western half of the second were in the hands of the Germans.

Nevertheless, the Russian strength did not yet permit of the large-scale counter-attack which alone could give them back the lost positions; and, rather than prolong, E. of Przasnysz, a third-line resistance which would be taken in flank and rear as soon as the victorious XVII. Corps should force the Przasnysz–Ciechanow switch-line, they decided to go back to the Bogate position forthwith. Thus the progress of the German XI., XVII. and XIII. Corps met with only rearguard resistance on July 14. Neither Przasnysz nor the switch-line was defended, while, to the W. of the battle-field, the German XVII. Res. Corps was able to advance, with no more than skirmishing, up to the outer defences of Ciechanow. The day's advance brought the infantry, but not the heavy artillery, of the attack group close up to the Bogate position, the eastern half of which the XIII. Corps in vain tried to carry with a rush at nightfall.

*Bogate (July 15–17).*—In two days the Germans had advanced over nearly half of the 24 m. of ground which separated them from the Narew line, and as yet the Russians had shown no important reserves—indeed, as late as July 12 troops were being withdrawn for the Mackensen front. The problem before the Germans was therefore to reach the Narew and master its crossings, if possible, before the enemy's reserves arrived and at the least to absorb these reserves in the defence of the river line. Speed was imperative, and the Bogate position had to be attacked with a minimum of preparation.

The Russian position was carefully laid out. On the right it followed the obstacle formed by the Orzyc from above Krasnosielc to Podos, whence it followed the edge of a wood to Bogate on the Wengierka. From Bogate a N.–S. switch-line, and from Podos a second switch, ran to Kamiewo, whence along a convenient stream the barrier continued to the Pultusk works. The W. half of the position—three to four parallel lines close to one another—was strong about Bogate and in the neighbourhood of Opinogora and Ciechanow. In the Opinogora sector, a night attack on July 14–15 gave the German 38th Div. possession of some advanced works and also a foothold in the first line itself near Zalocze Potory, but the advantage could not be exploited, and during the morning of July 15, while the artillery of the attack was still ranging, Gallwitz fixed upon the centre of the E. half—on both sides of Zielona—as the break-through front. Here there were put in, besides the 36th, 1st Guard Res. and 86th Divs., the newly arrived 50th Res. Div., while on the right of the 86th Div. Pfeil's Bde.—the only army reserve remaining—was to follow *en échelon*. The break-through force was to penetrate well to the S., then swing outward on both flanks, so as to force the evacuation of Ciechanow on the one side and to attack the Bogate–Karniewo switch-line on the other. The attack of the XIII. Corps and of Falk was to be frontal; and from the strength of the Russian position and the relative weakness of the attacking forces (three and one-half divisions as compared with five and one-half W. of Bogate) no more than local gains were expected till a break-through further W. succeeded.

It was not until after midday on July 15 that the attack could be launched after a brief artillery bombardment. But it was successful on the lines intended. The three and one-half divisions on the assault front broke through all the defences, and penetrated so far S. (the 38th and 35th Divs. conforming on the flanks) that the Russians evacuated Ciechanow during the night of July 15–16. Further W., the XVII. Res. Corps and Dickhuth's Corps progressed considerably toward the N. front of Novogeorgievsk, against no great opposition. But the Bogate–Podos–Orzyc river front of the defence held firm, as also did that part of the western position adjacent to Bogate.

On July 16, while the W. half of the break-through force—substantially, the XI. Corps—pushed on southward, driving the Russian rearguards before them to the line Sonsk–Golymin Stary, and the XVII. Res. Corps and Dickhuth's Corps advanced along and W. of the Ciechanow–Novogeorgievsk railway, the XVII. Corps, now comprising the 50th Res., the 1st Guard Res., 35th and 36th Divs., wheeled in against the Bogate–Karniewo switch-line, while the XIII. Corps and Falk assaulted the Bogate–Povos–Orzyc front in earnest. Both front and flank positions were stubbornly held. Local gains by the attack were nullified by local counter-attacks, and these were followed by new assaults. The 50th Res. Div. had not succeeded by nightfall in coming within several kilometres of Karniewo—the point at which the whole of the Russian position could be turned on their left; and on the other flank Krasnosielc, which equally afforded a gateway to the rear of the defensive system, was too strong to be reduced by direct attack. But between Bogate and Podos the Russian front line was forced along its whole length by the German 26th and part of the 3rd Divs., and the village of Podos, at the re-entrant angle of the position on the Orzyc, after changing hands more than once, was finally secured by the Germans about 11 P.M. Further N. the attackers had reached, but not passed, the Orzyc. But on the switch-line Bogate–Kamiewo the 36th Div. broke in at Krasne, 2½ m. S. of Bogate; and N.E. of Krasnosielc the I. Corps, hitherto passive, was now actively conforming to the advance of the XIII. and Falk, and at the same time condensing its forces on its right. The general idea of the situation formed at Hindenburg's and Gallwitz's headquarters was that the last Russian counter-attacks were meant only to gain time for another evacuation under cover of night—this time to the Narew and the bridgeheads. Accordingly, the German orders for July 17 not only directed the XI. (and part of the XVII. Res.) southward into positions for the attack of Pultusk, but deflected the 50th Res. Div. there as well.

*The Advance to the Narew (July 17–21).*—The impression of the situation formed by the German headquarters on the evening of July 16 was only partially correct. On the morning of July 17 the whole Krasnosielc–Bogate position and the northern position of the Bogate–Karniewo switch-line were found to be evacuated, or held only by light rearguards. But the German follow-up encountered more resistance than the similar operation on July 15. The Russians had in fact received the first of the expected reinforcements (about three divisions) and stood to fight, not indeed a battle, but a connected and determined rearguard action, on a line which, had it been completed, would have formed a third line of defence, similar to the Przasnysz and Bogate positions. This line had its origin at the point where the Krasnosielc–

**NARES, SIR GEORGE STRONG** (1831–1915), English Arctic explorer (*see* 19.246). In later life he acted as one of the conservators of the river Mersey. He died at Surbiton Jan. 15 1915.

**NAREW, BATTLES OF THE** (1915).—The lower course of the river Narew, with, on the one hand, its affluent the Bobr, and, on the other, the line of the lower Bug into which it runs, forms, against an invasion of Poland from East Prussia, a barrier which played a considerable rôle in the eastern front campaigns of the World War. This barrier was reinforced by bridgehead fortresses at Osowiec on the Bobr, Lomzha and Rozhan on the Narew, and Zegrze and Novogeorgievsk (or Modlin) on the Bug—the last named, a ring-fortress, bestriding also the Vistula and the Wkra and standing in close relation to the fortress of Warsaw. The course of the Bobr–Narew–Bug water-line is marked throughout by marshes, which, sometimes on one side of the water and sometimes on the other, but generally on both, vary in width from half a mile to 2 m. and at certain points broaden out into wooded marsh-basins, 6–10 m. in width or breadth.

Between this barrier and the S. frontier of East Prussia, inside which the western Masurian lakes offer lines of defence against Russian invasion, there were constant advances and retreats of each side during the first campaigns of the World War. The first Russian advance culminated in the disaster of Tannenberg (*see* MASURIA, BATTLES IN), and was followed by a gradual advance of minor German forces to the region of Wloclawek on the Vistula, Plonsk, Ciechanow, Przasnysz and Chorzelle, in conjunction with the main campaigns in West Poland. Then, early in 1915, the Russians prepared a great offensive, which was to take the same general direction as that of Aug. 1914. The Germans, however, by seizing the initiative early in Feb. delayed the development of this offensive. Their main effort, the winter battle of Masuria, was made on the E. front of East Prussia, while the S. front was guarded by an army group under General von Gallwitz, who carried out his task offensively, driving southward into the area N. of the Narew, where the Russians were assembling. This move led to very severe fighting, notably at Przasnysz; and Gallwitz, though reinforced by degrees, maintained himself with great difficulty against the onset of the Russian XII. Army. Then, gradually, the battle became stabilized, and, the great Austro-German offensive in West Galicia having from May 1 transferred the centre of gravity to the other wing, the country between the Narew and the western Masurian lakes was quiet for two months. It is a country of poor communications, sandy soil, low elevations, and numerous N.–S. streams—affluents of the Bobr, Narew or Bug—which occasionally turn into the E.–W. direction and offer partial lines of defence to either side. It is wooded, heavily so in its eastern portion, where the Narew and the Masurian lake zones converge.

Thus the Narew–Masuria battle-field, as it may be called, is triangular in shape, limited on the E. by the woods of the Pissek (or Pissa) region, lying between the Prussian Lake Spirding and the Russian fortress of Lomsha, on the S. and S.E. by the course of the lower Narew and lower Bug, and on the W. practically by the river Wkra and the fortress of Novogeorgievsk. Across this battle-field, in July 1915, the Russians held a front line roughly parallel to the Prussian frontier and therefore oblique to the Narew. It ran from the outlying defences of Lomsha on the right, by Cierlozy and Lipniki to Berdowelonki on the river Omulew, and thence by Cierpienta and Jednorozec on the Orzyc to Mchowko in front of Przasnysz; thence it continued a short distance westward to Grudusk, and at that point turned southwestward to the Vistula. This line was duplicated by rear defences, notably the "Bogate position" between Ciechanow and Krasnosielc; a switch-line connected Ciechanow and Przasnysz, another the centre of the Bogate position, and yet another the right of that position with the bridgehead lines of Pultusk. On the Narew itself, Lomzha, Rozhan and Pultusk (which already possessed works in peace) had been developed into large bridgeheads, and the modern permanent works at Zegrze on the Bug had been extended to include Serock at the Bug–Narew confluence. Novogeorgievsk, already a great ring-fortress in peace, had been surrounded by two enveloping rings of outer defences.

When, after the break-through of the Russian positions at Gorlice–Tarnow, Radymno and Grodek (*see* DUNAJEC-SAN, BATTLES OF THE), Mackensen's armies swung northward to reach the rear of their opponents in Poland by way of the upper Bug, a similar blow upon the N. side was planned by Falkenhayn for the armies under Hindenburg. As to the direction of this blow, there was acute controversy between Falkenhayn on the one hand and Hindenburg and Ludendorff on the other (*see* EASTERN EUROPEAN FRONT CAMPAIGNS, Part III.), and it was only by the pure assertion of authority that Falkenhayn imposed upon them the offensive on the Narew which is here described. Hindenburg and Ludendorff objected that, against so strong a series of positions as those of Przasnysz, Bogate and the Narew, there was no hope of such rapid progress as would enable Gallwitz to come in upon the rear of the Russians in West Poland in time to cut them off. The other arguments for and against a Narew offensive were of a more purely strategic character, and are not here considered, but it must be noted that each of these arguments, taken in itself, was proved by the sequel to be well founded. The view taken by Falkenhayn and that of Hindenburg and Ludendorff as to their relative importance in the *ensemble* differed fundamentally, Ludendorff's ideal being the cutting-off of the entire Russian army by the pincers closing from N.E. and S.E. on its rear, whereas Falkenhayn's object was more limited—to deliver a blow that would relieve pressure on Mackensen's front and so enable him to penetrate to Brest Litovsk from the south. To achieve this object, the offensive must, according to Falkenhayn, threaten the rear of the Russian positions in Poland at the earliest possible moment, and, therefore, by the nearest and shortest line of operations, since Mackensen was practically unable to start his movement along the upper Bug till the strength of the Russians in front of him had been materially reduced (*see* BREST LITOVSK, BATTLES ROUND).

Thus, although the record of Gallwitz's offensive on the Narew is one of slow frontal advances which aimed at the Russian communications but never reached them till the retreating enemy had passed on—although finally he could only join the German frontal armies in the general pursuit—the battles described below must be considered as successful or otherwise in relation to the object for which they were really fought. In the last analysis, they were, like the battles of the British army in Flanders in 1917, a relief-offensive, which in securing their object might, if fortune so willed it, secure other results as well.

*Forces and Positions.*—The portion of the front selected for attack by Gallwitz was that between the river Orzyc and the village of Grudok, in the middle of which lay Przasnysz; and the date chosen for the attack was July 12, afterwards changed to July 13. As already mentioned, the original cordon of troops along the S. front of East Prussia had grown by reinforcements during the spring battles in the Przasnysz region to the strength of an "army group," and for the July offensives it was given additional forces, though it was not till later that the title XII. Army was assigned to it. It consisted, from left (river Skwa) to right (river Vistula), of the I., XIII., XVII., XI., XVII. Res. and Dickhuth's Corps. Of these, the XIII., XVII., and XI. lay opposite the selected front with their divisions thus disposed. On the XIII. Corps front were the 4th Guard, the 3rd and the 26th Divs., with, on the left astride the Orzyc, a liaison detachment of the I. Corps under von Falk. On the XVII. Corps front, which extended from the Murawka stream to opposite Pavlovo-Koscienie, were the 36th Div.—its left facing Przasnysz—and the 1st Guard Res. Division. On that of the XI. Corps, which ran from the Russian salient N. of Pavlovo-Koscienie to Grudusk, the 86th Div. (of Landwehr and Ersatz units) and the 38th Division. From Grudusk southwestward, astride the Mlawa–Ciechanow–Novogeorgievsk railway, lay the 14th Landwehr Div. and 85th (Landwehr units) of the XVII. Res. Corps. In army reserve were the 35th Div., Pfeil's Bde. of the 14th Landwehr Div. and (after the first day) the 50th Res. Div.; later the 83rd Div., Menges's Div. and the 54th Div. were placed at Gallwitz's disposal by Hindenburg.

In the attack sector between Orzyc river and Grudusk the

battle of Dec. 26 1806 had been fought—and a more important outer system of well-organized trenches, which rested its right on the Narew at Chmielewo, traversed the Pelta at Szwelice, curved southward at Wojty Trojany, followed an affluent of the Przewodowka stream to Przwedowo, and a line of woods thence to Winnica, where it turned E. to rejoin the Narew 5 m. below the town. Except along the marshes of the Narew itself, the country inside and outside this line is largely wooded, with low sandy heights and small streams.

The weight of the attack was concentrated on two fronts: that adjacent to the Narew, where it was hoped to establish bridges and start an enveloping movement E. of the river as soon as the front Russian defences had been stormed; and that of the N.W. bend, where the super-heavy artillery, limited as it was to the good roads, could best take part. To the first of these attacks the 1st Guard Res. Div. near to the river, and the 50th Res. Div. above the village of Szlachekie, were assigned; and to the second the Landwehr and Ersatz units of the 86th Div., assisted by an active regiment lent by the 38th Division. The 85th Landwehr Div. and Pfeil's Bde. S.W. of Golymin Stary, was to flank-guard and eventually to take part in rolling up the Russian defence after the breach had been made. On the morning of July 23, after five hours' artillery bombardment, the assault was delivered. The 1st Guard Res. and 50th Res. Divs. carried all their objectives, after heavy fighting and—in some of the units of the 50th Res. Div.—fearful losses, and by noon had occupied all the area N. of the Pelta river. Here it was expected that the Russians would stand, but in the meantime the successful assault of the Landwehr and Ersatz on Wojty Trojany had broken down the left flank of such a defence, and the Russians were driven back, fighting with their characteristic group-stubbornness and lack of *ensemble*, to the inner line by nightfall. Here von Plüskow called a halt, suspending the storm of the forts till dawn on July 24. Meantime the 85th Div. and Pfeil, coming into the battle successively as planned, had made good a line from the right of the 86th Div. at Mosyn, on the Przewodowka brook, within the captured defences, to the Ciechanow–Novogeorgievsk railway near Klukowo, facing S.; and the 1st Guard Res. Div., falling out of the line as soon as the Pelta line had been reached, was crossing the Narew at several points both outside and inside the outer fortified line (Gnojno, Chmielewo, Lida) and forming bridgeheads and pontoon bridges for artillery. This threat of envelopment here induced the Russians to give up all hope of holding their last footing on the right bank, and during the night of July 23–24 they evacuated the inner line and the town, so that soon after dawn on July 24, the pioneers of the 50th Res. Div., instead of being engaged in wire-cutting before the forts as had been anticipated, were at work on the broken river bridge.

This crossing of the 1st Guard Res. Div., and its entrenchment of a large bridgehead in the Szygowiec loop, was only part of a large programme. To the left of it the 38th and 36th Divs. of the XVII. Corps effected passages at Zambski, Kalinowo and Rowy, without any great difficulty save at the first named, where the direct effort failed and the defence had to be dislodged by a flank movement from the Kalinowo crossing-place. The construction of artillery bridges was put in hand at once, in spite of the interdictive fire of the Russian artillery, for it was urgently necessary, from the defensive and the offensive standpoints alike, to push the XVII. Corps and 1st Guard Res. Div. southeastward so as to seize the line of the little river Prut which makes a barrier from the E. end of the Bagno Pulwy to the lower Narew, and incidentally to cut off as many of the defenders of Pultusk as possible. By the night of July 23, the 38th and 36th Div., like the 1st Guard Res. Div., had been able only to establish their bridgeheads firmly, but by that of July 24 the artillery bridges were mostly completed, and the German outposts to the right of the Bagno Pulwy stood on the line Rzonsnik–Sadykierz (38th Div.)—woods E. of Bartodzieje (part 50th Res. Div.)—E. of Gladczyn (1st Guard Res. Div.)—N. of Drusly (86th Div.), [illegible] the protective line of the 85th Div. and Pfeil, W. of the [illegible] to near Nasielsk. East of Pultusk in reserve was the [illegible] derived Menger Division. Meantime, on the German left the 36th Div., from its crossings at Kalinowo and Rowy, had proceeded due eastward, in concert with an advance of the 35th Div. along the N. of the Narew, and by the evening of July 24th these units, guarded on their right by the Guard Cav. Bde. in the Bagno Pulwy, stood E. of the Narew between Adamowo and Ostrykol inclusive.

On July 25 the German forces E. of Pultusk advanced to the line of the Prut, while the Guard Cav. Bde. spread across the Bagno Pulwy, and the two divisions of the XVII. Corps pushed forward their bridgehead position of Adamowo–Ostrykol somewhat; on the left of these, the 26th Div. of the XIII. Corps extended the line to the Orz river. But at all points resistance to the advance became ever stronger, and it was evident that for further progress yet another break-through battle would be necessary. The Germans therefore halted, to gain time for their artillery and their transport to overtake the fighting line.

*Rozhan and Kamionka (July 22–25).*—The bridgehead of Rozhan possessed an inner line of permanent forts, more modern than those of Pultusk, and an outer line which, beginning at the river edge N. of Dysobaba, followed a sinuous trace by Miluny, the wood N.W. of Podbora, and Point 132 S. of Podbora, and rejoined the river opposite Prystan. But it differed radically from Pultusk in being smaller and also segmented internally by several switch-lines. The German XIII. Corps headquarters, therefore, in spite of the need of rapid action, decided to take the segments by successive efforts in each of which the whole artillery could be employed. Already, on July 20, the first of these efforts had carried the salient of Hill 132, as recorded above, before the Russian counter-attack suspended operations. On July 22, after a day's delay, the 4th Guard Div. made the next effort against the Miluny works, which, with the village behind them, were carried by assault before night. On July 23 it was the turn of the woods N.E. of Podbora, which fell to assault by the 3rd Division. Thus on the morning of July 24 all the outer segments were in the hands of the Germans, and the assault of the main line (lying in front of the fort-line) was prepared. But here also the Russians evacuated the bridgehead without standing an assault, and fell back into the woods lying E. of the Narew. Thenceforward the line from Prystan to Chelzy—continued thence northward by the dominant heights of the left bank to Ostrolenka and beyond—formed a position in which the Russians meant to make a prolonged defence.

The sudden cessation of resistance at Rozhan seems to have taken the Germans unawares, for, although the place was occupied in the early hours of the morning, no real effort was made to win a passage until late in the day, in spite of the command of the right bank over the left and the presence of three divisions of victorious infantry. The 26th Div., hitherto investing the S. front of Rozhan, was ordered to cross the Narew between Dzbondz and Bruzie Wielkie, but, being repulsed with heavy loss in an attempt at Dzbondz, it crossed further down at Bruzie Wielkie and so passed away into the scope of the XVII. Corps operations, divided from those of the XIII. by the marshes of the Orz–Narew confluence. The 3rd Div., pursuing through Rozhan, found, late in the day, a Russian bridge S. of Dysobaba, and began passing small forces over towards the wooded heights S. of Dombrowka. But it was not till daylight on July 25th that three battalions had been assembled on the other side, and a sharp action was necessary before the line Prystan–Dombrowka was secured at nightfall. The 4th Guard Div., after fruitless attempts on the afternoon of July 24 to cross at Dysobaba and at Sielun, passed small detachments over during the night of July 24–25, and gradually made good the line Dombrowka–Point 121 with an artillery bridge at Sielun, before daylight on July 26.

Above the Rozhan battle-field, on the front of the German I. Corps, the wide extent of the front (Sielun–Ostrolenka), and the commanding positions on the wooded left bank, made a crossing on a broad front impossible. The Germans had reached the river on July 20, unaffected by the Russian counter-stroke of that day, which did not extend N. of Rozhan, and after reconnaissance fixed upon a bend above Kamienka as the main crossing-place. Here the 2nd Div. was to make the venture

while the 83rd. below and the 37th. above were to make feints as far up as Ostrolenka. But the Russians were on the alert all along the line. In the night of July 23–24 the leading troops of the German 2nd Div., covered by an intense artillery fire, waded the Narew, under fire from the hostile machine-guns, by an imperfectly known ford. At the cost of heavy losses they secured a foothold on the further heights, but no reinforcements or supplies could reach them. The Russians—high-quality Siberian troops—counter-attacked fiercely, but, being armed in the main only with hand grenades, they were beaten down, time after time, by the rifle-fire of the small German force, though one reckless onset was nearly successful. In the night of July 24–25 more German forces were got across piecemeal, till in all there were six decimated battalions in a bridgehead 1,500 yd. wide and 500 yd. deep, unable to advance or retreat. The feint-crossings on the fronts of the other divisions had been discontinued, though at Modzele a small foothold had been gained by part of the 83rd Div.

Next day, July 26, while at Kamionka the isolated struggle went on as before, the long-expected Russian counter-attack in force broke out along the whole line from the Novogeorgievsk railway to Chelsty above Rozhan.

*Battle of the Orz, or Goworowo (July 26–Aug. 3).*—In accordance with orders from "General Headquarters, East," von Gallwitz had planned, for July 26, a general offensive against the line Wyszkow–Ostrow, while continuing to hold the line S. of Pultusk defensively. He intended that the XVII. Res. Corps (86th and 1st Guard Res. Divs.) and XI. Corps (50th Res. and 38th Divs.) should break out over the Prut, along the S. side of the Bagno Pulwy, while the XVII. Corps (38th and 39th Divs.) pushed E. from their Ostrykol bridgehead, and the 26th Div. by a flank movement from the S. assisted the rest of the XIII. Corps to clear the woods E. of Rozhan. Menges's Div. was in reserve and the 54th Div. due to arrive from France. The I. Corps' attacks—increasingly important in the general scheme of battle in proportion as the Russians in West Poland gave ground—were to be intensified by adding to them the expected 54th Division. But when, on the morning of July 26th, these movements had not reached the stage of infantry activity, some 16–18 Russian divisions rushed to the assault, covered by a fire which was made possible by a hitherto husbanded ammunition supply. On the Prut front, delivered by forces probably not greatly exceeding those of the Germans, the assault failed to penetrate except momentarily at Pniewo on the Pultusk–Wyszkow highroad; and on the dangerous W. flank of Gallwitz's Army, the line Karniewek–Blendostwo–Nasielsk, held only by the 85th Landwehr Div. and Pfeil's Landwehr Bde., the onset of three Siberian and Turkestan divisions was checked after a crisis near Blendostwo. The "sympathetic" attack of a division against the German 86th Div. on the lower Prut was equally heavy and equally unsuccessful. But the effort of the battle, and especially the risk of its renewal on the front W. of the Narew, made the Germans postpone their offensive from the Prut front for two days.

Against the front of the German XI. Corps and 26th Div. some two and one-half to three Russian divisions, attacking regardless of losses, promptly brought to an end the forward movement begun from the Ostrykol bridgehead, and prevented the German 26th Div. from intervening in the flank of the woods E. of Rozhan. There, so far from being able to progress eastward, the Germans were repulsed by the onset of three to four divisions assembled W. of Goworowo and were in danger of being thrown back on to their bridges, only 1½ m. behind the line of battle. An accidental reinforcement from the I. Corps, viz. the arrival of part of the 83rd Div. seeking a way round to the rear of Kamionka by using the 4th Guard Div.'s bridge at Sielun, enabled the German XIII. Corps to regain the lost ground at Dombrowo and Kaszewic and the Russian attack died away. At the bridgehead of Kamionka, infantry counter-attacks were less vehement, but artillery effect upon the gradually increasing mass of Germans in a confined space was terrible, and the Higher Command decided to discontinue the effort to push eastward from so unpromising a base. Already the commander of the 83rd Div. had—as noted above—sought a way round, and preparations were made to profit by this initiative by bridging the uncommitted forces of the 2nd and 37th Divs. over a bridge to be thrown near Kolaki as soon as the 83rd Div. should have passed that point. Meanwhile, the newly arrived 54th Div. was to attempt another passage at Ostrolenka, while, further up, the VIII. Army was to force a crossing near the Skwa mouth, preparatory to an advance against the Lomzha–Bialystok region.

On July 27 the Russian attacks, instead of increasing in violence, began to break down into local and spasmodic efforts, though these efforts continued S., S.E. and E. of Pultusk till July 29. On this front the German Command decided, on July 27, to stand henceforth on the defensive, for Ludendorff, ever pressing for maximum results, was striving to keep the centre of gravity of the offensive well N. of the Bug, in spite of the smallness of the tactical gains that had been secured at Ostrykol, Lomzha and above. On this and the following days there was little change in the situation at Ostrykol bridgehead, but E. of Lomzha the Germans reacted with great vigour. In the centre the 3rd Div., on the left the 4th Guard Div. supported by part of the 83rd Div. of the I. Corps, and on the right the 26th Div. working its way N.E. from the Ostrykol line to rejoin its corps, swept the Russians back to the line Josefowo–Goworowo–Rembisze by nightfall on July 27, while the main portion of the 83rd Div. struck out northward according to its original purpose, and reached Cisk, Lipianka and even the S. edge of Kamionka village, thus opening the passage at Kolaki for the mixed forces of the 2nd and 37th Divs. gathered there, and freeing the worn-out troops in the Kamionka bridgehead.

From that point the battle N. of the Bagno Pulwy became, in the main, the slow driving of an enemy who, although his fighting energy was becoming exhausted by disaster, was holding ground to gain time for the safe passage of his retreating frontal armies. Besides this resistance, difficulties of communication and supply made the follow-up much slower than it had been from Przasnysz to the Narew. On July 28 the 54th Div. made its attempt at Ostrolenka and failed, and it was brought round next day to the Kolaki bridge, over which the mixed elements of the 2nd and 37th Divs. were then streaming to join the 83rd. On July 30, after the last Russian counter-attacks on the S. front had died away, Gallwitz withdrew the 1st Guard Res. Div. which was sent to join the forces N.E. of Rozhan. By July 31 there were between the Ostrykol and the Kamionka bridgeheads, on a line passing through Josefowo–Goworowo–Cisk–Narew below Kordowo, ten divisions against not more than four of the Russians. But some of these ten divisions were worn out; and a Russian counter-stroke on July 31, which at Cisk fell upon and broke the Landsturm and Ersatz units of the 83rd Div., which had already lost over 3,000 men, imperilled the whole German offensive for a time. Nor was it till the evening of this day that the Russians finally gave up the pressure on the Kamionka bridgehead.

This, however, was the last offensive effort of the Russians on the Narew front; and a continuance of the German movement northeastward led, on Aug. 3, to their giving up the defence at Ostrolenka, which was the less tenable as von Scholtz's VIII. Army had by this time crossed the Narew in two places higher up.

The final situation (Aug. 4) of the Germans after the Goworowo battle, which was also the initial situation of the battle of Ostrow, was as follows:—XVII. Res. Corps (Pfeil, 85th, 86th Divs.), Nasielsk–Pniewo; XI. Corps (38th Div. and Menges's Div.), Pniewo–Bagno Pulwy; Guard Cav. Bde., Bagno Pulwy; XVII. Corps (35th and 36th Divs.), a m. W. of Wyszkow–Ostrolenka railway, from Sleszchy to Kobylin; XIII. and I. Corps (26th, 3rd, 4th Guard, 1st Guard Res., 50th Res., 54th, 83rd, 2nd and 37th Divs.), on the line Josefowo–Czarnie–Nogawki–Troszyn–Kurpie Dworskie on the Ostrolenka–Bialystok railway. The left, on the Ruz, was in touch with the right of Scholtz's Army.

In the three weeks of the German Narew offensive (July 13–Aug. 3), the Gallwitz Army Group captured in all about 30,000 prisoners, and with them only 14 guns and 150 machine-guns—an unusual disproportion, which clearly indicates the way in which the Russians, in the summer of 1915, conducted their defence. (C. F. A.)

**NAROCH LAKE**, in Lithuania (formerly in the Russian Government of Vilna), the largest of the numerous lakes in which the tributaries of the Vilya and the Disna have their origin. It is nearly equidistant from Vilna (62 m.) and from Dvinsk (72 m.), and lies 37 m. N. of Molodechno railway junction. The lake, which measures 8 m. by 6 m. at its longest and widest, drains into the small river Naroch, which, receiving another stream from Lake Viszniev at the village of Naroch (21 m. S. of the lake), flows on to join the Vilya E. of Smorgon. In Sept. 1915 this region witnessed the last attempt of Hindenburg to reach the lines of retreat of the Russian armies, and the successful counter-attacks of the latter (battle of Vilna-Molodechno). Next spring it was the scene of the great battle described below.

*Battle of Lake Naroch, or Postavy (March 18–27 1916).*—The conclusion of the German advance in 1915 had brought the German forces in this quarter on to a general line that ran from Lake Drisvyaty—the limit of the Dvinsk front—by Bidsy and Postavy to Lake Naroch and thence to Smorgon on the Minsk–Molodechno–Vilna railway, from which place it continued through Baranovichi southward. Although, broadly, this line runs N. and S., its course was really somewhat sinuous, conforming as it did to natural lines of defence, which in the campaigns of the Russian front are of supreme importance owing to the fewness of communications and the low economic development of the country. From Drisvyaty to Smorgon (about 95 m.), along the sinuosities of the actual line, only five gaps of more than about three miles wide exist in the barrier of lakes, rivers and marshes. These gaps lie N. of Vidzy, near Postavy, and on the proximity of Lake Naroch; and it was naturally at these points that the military efforts about to be described focussed themselves.

In the region of Lake Naroch the German line, held defensively since the close of the 1915 campaign, broke out of the general N.–S. direction into a salient, which, though weakened by the circumstance of its having 4 of the 5 gaps above mentioned on its front and flanks, offered a strong protective water-line, and so required relatively few troops to hold it. This salient, having about 45 m. of trench or water front, and a depth at its centre of about 10 m., was in no sense a "pocket," and the chances of its becoming so by pressure on its flanks were limited by the narrowness of the gaps on these flanks that an assailant could use. Indeed, the higher authorities of the German east front seem to have expected an attack, not on the salient itself but further S., about Smorgon, where a rapid western advance by the Russians, with relatively good communications behind them, might have converted this flat salient into a really dangerous bulge. The Russian Command, however, chose otherwise.

In the N. the salient began at Vileity, where the course of the Komaika stream bends sharply westward and ceased to protect the German front. Between Vileity and Moscheiki is a gap 3½–4 m. wide, and at Moscheiki, taking contact with another stream, the Olsiza, the line of defence began to follow a chain of small lakes and streams that is only broken by very narrow gaps between lake and lake till the greater Lake Miadzol is reached. Thus the Vileity–Moscheiki gap was the only place between Vidzy and Lake Miadzol at which the conditions were favourable to a great offensive. The front available was narrow, and communications poor, but great forests were available for the concealment of the attack preparations and the artillery. Though the gap is partly marsh, the Germans had preferred to run their line nearly straight across it—close up to the edge of these forests—rather than withdraw it some miles back to higher ground and leave the Vileity positions, on the one side, and the Moschelki position, on the other, as dangerously advanced salients. Given sufficient troops and means and an improvement of the routes within the forests, it seemed that the breaking of the German line could be ensured, and once it was broken a vigorous drive southwestwards would take the attackers on to higher ground, where they would envelop the left limb of the salient and reap their harvest of prisoners and *matériel*.[1] Further, by obtaining control of the railway line Postavy–Novosventsyany, they would be in a position, later, to push an advance against the Vilna–Dvinsk line, the artery of the German N.E. front. Lakes Miadzol and Naroch and the solid ground between them formed the flattened apex of the salient. In front of them, protecting the avenue to some extent, lie other lakes. Approximately at Lake Miadzol lies the watershed between the Disna and Vilya systems. The southern limb of the salient was short (7½ m. in a straight line). It began at Bliznika on the shore of Lake Naroch and ended on Lake Viszniev near Ostrovlani. But the trace of the line, dictated by the ground, was peculiar and considerably influenced the course of the battle. Between the two streams that connect Lakes Naroch and Viszniev with the Vilya basin lies a wide area of marsh, but this area is traversed by two long land-bridges of higher, sandy ground, each 3–4 m. in breadth, which, running in from the E. and the S. respectively, converge in well-marked hills near Nosovice. Between these land-bridges the marsh drives a deep wedge, so that both for attack and for defence the southern face of the salient was divided into two distinct areas, which were connected, for the defence, by a trench-line across the narrowest part of the marsh, and, for the attack, by various islands of dry ground in the midst of the marsh whence enfilade or oblique fire could be brought to bear on the ridge; for, in order to minimize the frontage of his marsh-trenches, the defender placed them far up the wedge, leaving his positions on the sand-ridges as salients. Specially dangerous for the defence was the position on the E.–W. ridge, which ran close to Naroch and could be enfiladed both from the "islands" in the marshes and from the opposite shore of the lake. Here purely local conditions—the need of securing possession of what, for the region, are commanding hills—brought the German line to a positive apex. On the other hand, though a successful Russian offensive could be pushed along either or both the land-bridges, as far as their junction about Nosovice, advance beyond that village was barred by the Perekop stream, which, rising close to Lake Naroch and emptying into Lake Viszniev, cuts right across the dry land avenue, while, further, a long lake lying behind Viszniev would cramp the left flank of the advancing victor and limit him for many miles to the same frontage as that of his original attack. Thus the most that he could expect from success in this quarter was the seizure of a barrier or anvil (the Perekop), against which the garrison of the salient might be driven by hammer-blows from the Moscheiki gap.

The military features of the Naroch salient, then, afford an excellent example of the way in which strategic and tactical values change according to the scale of the operation contemplated. In the case of quite small operations, the salient must be regarded as very strong, while for a grand offensive on the largest scale—the case considered by the German Higher Command—the centres of gravity lay not in the salient itself, but away to its flanks, where the possibility existed of converting it into a great strategic "pocket." But, for the intermediate type of operations—the large-scale effort aiming at tactical and moral rather than strategic results—the attack possibilities, even on the short flanks of the salient itself, were not inadequate; and it was against this type of attack—too heavy for the local troops to meet, yet not so heavy that the Higher Command could afford to expend its entire reserves in supporting them—that the defence was, in the *ensemble*, weakest. This was the case that actually occurred, and it imposed the maximum strain both on the German fighting troops, who were called on to make head against great odds, and on the German Higher Command, for which (as Ludendorff's memoirs show) the correct disposition of the reserves was a matter of extreme difficulty and anxiety.

The choice of this intermediate form of offensive by the Russians was, however, not deliberate, but imposed by unforeseen events. Their original intentions and their first preparations were based on the decisions of the inter-Allied conference, which fixed July 1 as the date at which great offensives would be launched simultaneously on all fronts. But in Feb. the Germans forestalled this plan by attacking Verdun with such power and fury that the western front was thrown into a state of acute crisis. Repeated calls were made by the French for a relief offensive in the east,

[1] A switch-line was drawn across this higher ground from Godutsishki S.E. to the main position just N. of Lake Miadzol. But this line was incomplete at the time of the battle.

and the Tsar decided that these calls must be answered. Preparations were therefore expedited, and concentrated upon the Naroch salient, an objective evidently suited for such an offensive, and one in which local gains would improve the prospects of the later, main offensive contemplated.

The technical and tactical fitness of the Russian army for a trench-warfare offensive, however, was still low—as indeed it remained throughout 1916. Guns and munitions were available on a larger scale than in 1915; new methods had been adopted from the French fighting regulations of autumn 1915; and the army was stronger than at any previous period, in spite of its appalling losses.

But, instead of five months in which to study the application of these new methods to Eastern conditions of armament and communications, and to inoculate the army generally with the doctrines thereby established, there were now only a few weeks available, and this handicap was the more important as the army was now, substantially, a new army. It was the product of the wave of patriotic fervour which had followed the defeats of 1915.

Hitherto, the army in the field had been practically the peace army with its reserves, the latter trained to the same ideas and broken to the same discipline as the active troops. No new creations had been put into the field corresponding to the German "new reserve" formations of Sept.–Dec. 1914, or the British territorial and new army divisions. Surplus resources of the peace-trained categories, and batches of war recruits as well, had been absorbed in the system of the old army to replace casualties. But from Sept. 1915, when the Tsar assumed personal command and proclaimed a war of liberation, moral forces which had been excluded from, or scarcely tapped by, the old army system came into play. Recruiting and war-work were galvanized by a new spirit, and the Russian leaders, habitually more reckless in the expenditure of human life than those of the Central and Western European nations, now found themselves in control of new masses which, in reality, stood in need rather of control and economical management than of driving.

Given those moral and technical factors, the course of the Russian spring offensive of 1916 almost explains itself. Hasty preparations in the hinterland, ruthless urging-on of enthusiastic and inexperienced troops in the front line, might suffice in the open-field shock of crises such as Ypres or Lodz; but in a trench-warfare offensive of limited scope, under peculiarly difficult conditions of ground and weather, they could only lead to costly defeat, except against an unusually weak opponent. Such an inferiority on the defender's side, however, the Russian staff was justified in assuming. Between Pinsk and the Baltic they had about 75 divisions, each of 16 battalions, to the enemy's 44, most of which had 9 battalions only; and it was possible with these proportions to keep numerically equal or superior forces on all parts of the line, while assembling very greatly superior masses at the points of attack.

The German dispositions were accurately known to the Russian staff. From the river Disna to Krevo (S. of Smorgon) was the point of von Eichhorn's X. Army. At the beginning of March 1916 there were, between these limits:—the 17th Landwehr Div., Bavarian Cav. Div., 3rd Cav. Div. from river Disna to Vileity inclusive, grouped under "No. 6 Cavalry Staff" (Gen. von Garnier); the 42nd, 115th, 31st and 75th Res. Divs. and 9th Cav. Div. (reconstituted as a normal infantry division) under XXI. Corps headquarters (Gen. von Hutier), round the Naroch salient to Lake Viszniev inclusive; the III. Res. Corps of two divisions, from Viszniev to Smorgon exclusive; and the XL. Res. Corps, at Smorgon and Krevo. Behind his centre, in the salient, Eichhorn placed his army reserve, the 80th Res. Div. Counting in the last named, this gave an average density of one battalion to the mile over the whole front (the equivalent of 87 battalions for 85 miles). In winter the front had to be fairly evenly held, as the lakes gave only a diminished protection till the thaw should set in. Nowhere did it reach a density of two battalions per mile, except at the most exposed point—the apex of the line on the land-bridge S. of Lake Naroch on the dangerous Vileity–Moscheiki front—where it was about one and one-half. As a comparison it may be noted that, at the Somme, von Below's I. Army had an average density of three battalions to the mile.

On the Russian side General Ragosa (commanding the II. Army in succession to Gen. Smirnov) disposed of 11 infantry divisions and one cav. div. in line, viz.—I. Corps of three divisions N. of Postavy (exclusive); XXXIV. and IV. Siberian Corps, four divisions, from Postavy (inclusive) to Lake Naroch (exclusive); and V. and XXXVI. Corps (four divisions) and Ural Cossack Div. facing the Naroch–Viszniev front, besides other forces in the same proportion opposite the German III. Res. and XL. Res. Corps. For the battle, these were reinforced by the I. Siberian, XV. and XXVII. Corps (six divisions), and 6th and 8th Cav. Divs. in the forests facing Vileity–Moscheiki, and by the III. Siberian and XXXV. Corps (four divisions) opposite the Naroch–Viszniev front. In all, then, there were 21 infantry divisions and 3 cavalry divisions, equivalent to about 345 battalions of infantry. Elaborate measures were taken to keep this concentration secret. Some of the combats initiated with the object of misleading the German command almost ranked as battles, notably the fighting of March 19–26 at Jakobstadt on the Dvina; and, although von Hutier kept "General Headquarters, East" informed as to the forces gathering on the Naroch front, the collation of his reports with those from other sources did not enable Ludendorff definitely to discern the real point of attack till the eve of the battle. Moreover, even within the salient itself, von Hutier was unable to accumulate his meagre forces on the flanks, for the lakes along this front were still frozen hard. At the last moment Ludendorff sent the XXI. Corps one fresh division, the 107th, and detailed others (86th Div., half 85th Div., 119th Div. and one regiment) to follow in succession, if required. The Russian surprise concentration, in short, was successfully achieved, in spite of all the handicaps of trackless hinterland, hurry and enemy vigilance. At 6 A.M. on March 18 the Russian artillery opened fire on the Naroch–Viszniev front—with an intensity that the Germans had never yet experienced on the eastern front—followed at 7 A.M. by that on the Vileity–Moscheiki front, which took under fire also the defenders N. of Vileity and those S.E. of Moscheiki as far as beyond Postavy.

The main lines of the struggle which followed were governed by the conditions of terrain and of *moral* above discussed. As in the case of the French offensive on the Aisne thirteen months later, the significance of the battle lies less in its incidents than in its general results. On the first day, after a bombardment which was at first very effective but fell away later as the Russian batteries were picked up successively by the German artillery, masses of infantry debouched to the attack on the Vileity–Moscheiki front and the Naroch land-bridge, the Viszniev land-bridge being at the same time attacked by smaller forces. In the night of March 17–8, and on succeeding nights, various attacks were delivered on the minor gaps in the lake barrier between Postavy and Lake Miadzol, and they had the effect of keeping von Hutier constantly anxious for the security of his front, and so—till the arrival of the fresh divisions—limiting the reinforcements available for the Vileity–Moscheiki and the Naroch–Viszniev fronts, on which the weight of the Russian offensive was concentrated

The Russian infantry attacks, which began after 3–4 hours artillery preparation, were extremely violent but disjointed. The defending artillery was worked to a well-prepared scheme, and (according to German accounts) assisted by sound-ranging posts. On the N. flank its counter-battery shooting into the forests had the effects of what later came to be called a "counter-preparation." In the débris of trees and bushes, the Russian infantry attacks lost unity and force, and were delivered at different times on different sections of the front. The available Russian artillery could thus devote itself to each objective in turn, but, on the other hand, the more efficient artillery of the defence could concentrate on each assault as it debouched over the glades separating the Russian forests from the woods in the German line across the marsh. Thus the German infantry, though very much inferior in numbers, was able to stand assault after assault, while suffering heavy losses under the Russian

artillery fire and holding defences that were breastworks rather than trenches; and at nightfall the Russians drew back into the forests, having suffered enormous casualties without reaching the enemy's trenches at any point. Attacks on the village of Vileity, held by the right of the German 3rd Cav. Div., were equally futile. On the Naroch–Viszniev front also the assaults were fierce but disunited, and here too the artillery of the German 75th Res. Div. and 9th Cav. Div. could focus its efforts on each assailant in turn, even that of the III. Res. Corps S. of Lake Viszniev co-operating at times. In sum, the Russians, on the first day, suffered useless and terrible losses in regimental assaults delivered against steady infantry, uncut wire and skilfully handled artillery.

For the following night and day, the Russians changed their tactics. The artillery devoted itself to the demolition of trenches, to wire-cutting, and to the harassing of the billets in the villages behind the defenders' lines, with frequent small infantry attacks intended to force the defence to man its trenches and to march its reserves hither and thither. In this policy they were to some extent successful; the first of the German reinforcing divisions to arrive, the 107th, was put in piecemeal to stiffen the Vileity–Moscheiki front. Outside the battle-field, Russian threats at Vidzy, at Jakobstadt and elsewhere grew more serious. Then, in the night of March 19–20 massed attacks were delivered on the Vileity–Moscheiki front.

The weather conditions both for attackers and defenders had now become terrible. On March 15 a thaw had set in, which, but for Verdun, would probably have caused Ragosa to postpone the whole operation. By March 20 it had reached such a point that the ice on the lakes was covered by 2 ft. of water, while the German trenches in the marshes, no longer pumped out, were waist-deep, and the communications were mere mud. Exhausting as were these conditions for the German soldier, they were paralyzing for the Russian staff. In the forests, which were not seamed with tracks like an Argonne or a Bois le Prêtre, formation for attack and transmission of orders and supply became almost impossible. The night attack on Vileity and on the woods near Moscheiki was utter confusion for both sides. Part of the German defence system was overrun in the first assault, but in the haphazard, frequently hand-to-hand, fighting that followed, superior cohesion and coöperation defeated superior numbers, and the Germans regained the lost trenches, with the aid of parts of the 107th Div. On March 20 the Germans began to receive further reinforcements, the 86th Div. and half of the 85th Div. (170th Bde.). These, however, were held for the protection of the centre and the S. front of the salient, and only the 80th Res. Div. was moved somewhat to the north.

On the night of March 20–1 the night assault was repeated, this time with larger numbers and simultaneously on both the battle fronts. On the N. flank, the assault swept over parts of the defences as before and penetrated deep into the marsh-woods, seeking especially to drive S. and S.W. on to the higher ground behind Postavy. Again resolute counter-attacks stopped its progress, but this time the Russians retained possession of the captured front trenches. On the land-bridge S. of Lake Naroch, a wild assault swept completely over the German 75th Res. Div. holding the "apex," and it was with difficulty that the defenders' line was reconstituted some kilometres farther back. Only on the Viszniev land-bridge was the assault definitely repulsed. The situation for the Germans became extremely critical. But again it was saved by counter-attack. On March 21 the last forces of the 107th Div., with the exhausted 42nd Div., retook the marsh trenches from the equally exhausted Russians; and on the Naroch land-bridge the putting-in of the whole 80th Div. (brought back from the N.), with parts of the 170th Bde. and 86th Div., not only stabilized the defence but gave it the upper hand. Then it became possible to relieve the exhausted 42nd and 75th Res. Divs. by fresh troops.

The battle continued for a week longer, on the same lines as in the critical days, but with decreasing intensity on the part of the Russians. Presently the lost "apex" was recovered by the Germans, and nearly a month later a local attack still further improved the position on the Naroch land-bridge. But by that time the whole front had become quiet. The last severe battle-day was March 26; after that date the Russian relief-offensive expired without having caused one German soldier to be brought over from France. The German Eastern Headquarters had passed through a period of extreme anxiety, and it is arguable that on March 17–8 they were taken by surprise. But, if so, their recovery was instant, and they managed to meet the calls of the defence out of their local reserves. For the Russians, the first offensive of the new armies was a disaster of far-reaching importance. Prepared, up to the moment of launching, with great adroitness, it had been "choked in blood and marsh" with an enormous cost in mass-casualties and mass-disillusionment.

(C. F. A.)

**NATAL** (*see* 19.252).—At the 1911 census the pop. of Natal, S. Africa, was 1,194,043, of whom 98,114 were whites, 953,398 Bantu, 133,439 Asiatics and 9,092 of mixed or other coloured races. Compared with 1904 the white pop.—which between 1891 and 1904 had nearly doubled—was practically stationary; there was an actual increase of 1,005. In 1918 a census of the whites showed that they numbered 121,931, evidence that the check in their increase had been temporary only. Natal, though the smallest, is the most densely populated province of the Union, with 37·40 persons to the sq.m. in 1918. The white and Asiatic pop. is mainly concentrated in Natal proper; of the Bantu 214,969 lived in Zululand at the 1911 census. Of the total coloured pop. in 1911 only 13·84% were returned as Christians (compared with 44·20% in the Cape). The chief towns were Durban (89,098) and Pietermaritzburg (30,555; in 1919 35,322). Ladysmith ranked next with 5,594 inhabitants. Pietermaritzburg, the capital, has handsome public buildings, including those of the provincial council and Natal University College.

The change from the status of a self-governing colony to a province of the Union affected Natal politically more closely than any other province since in it alone were the great majority of the white inhabitants of British descent. In the first Parliament of the Union the Natal members took an independent position, and the firm attachment of Natalians to the British connexion continued an unchanging factor in the S. African situation. Provincial administration was, however, carried on upon non-party lines (for the provincial system of administration *see* CAPE PROVINCE). The first administrator was Mr. C. J. Smythe, who had previously held office as Colonial Secretary and as Prime Minister of Natal. Mr. Smythe, who was reappointed for a second term in 1905, died in 1918 and Mr. G. T. Plowman succeeded to the post. The revenue raised in the province, derived chiefly from transfer duties and licences, increased from £118,000 in 1912–3 to £172,000 in 1917–8, the subsidies from the Union Government varying from £361,000 to £375,000. Over half the total expenditure was on education, the sums spent for that object rising from £169,000 in 1912–3 to £285,000 in 1917–8.

Natal was deeply interested in the question of Indians in S. Africa. Of the 152,309 Asiatics in the Union in 1911, no fewer than 149,791 were British Indians and of these 133,048 lived in Natal, where they had rendered possible the development of the sugar, tea and wattle industries, as well as providing labour for the coal-mines, railways and other public works. Besides labourers, there were many Indians engaged in professions and commerce. White S. Africans in general opposed the further increase of Asiatics in the Union; while, in 1911, the Indian Government, long dissatisfied with the attitude of Natal to Indians, prohibited the recruitment of indentured coolies. The Indians both in Natal and the Transvaal complained of many grievances, among them of the poll tax imposed in Natal on all non-indentured Indians. Their cause was championed by Mr. M. K. Ghandi, then resident in S. Africa. Arising out of the agitation, riots and disturbances occurred in Natal in 1913. Some 2,700 Indians started to march to Johannesburg. About 500 were stopped on the border; the rest entered the Transvaal, but were eventually induced to return. In 1914 the poll tax on Indians in Natal was abandoned while the Union passed legislation designed to prevent, with some few exceptions, the entry of further adult male Asiatics into S. Africa and to restrict Asiatics to the provinces in which they were resident. The so-called Smuts-Ghandi agreement of the same year was designed to guard the vested interests of Indians already in the Union (*see*, further, SOUTH AFRICA).

A notable element in the progress of Natal has been the development of coal-mining. The output, which in 1910 first exceeded 2,500,000 tons, rose to over 3,000,000 in 1916, but fell to 2,600,000

tons in 1918, the decline being attributed to the effect of the influenza epidemic of that year. In 1919 the output was 2,800,000 tons. Natal coal is of excellent quality, and commands high prices—double that of Transvaal coal. In 1918 the output was valued at £1,358,000. (F. R. C.)

**NATHAN, ERNESTO** (1845–1921), Italian politician, was born in London in 1845, and died at Rome on April 9 1921. He was the son of an Englishman, Joseph Nathan, and of an Italian mother, Sara Rosselli, both Jews. His parents had befriended Italian political exiles in England, and on the death of Joseph Nathan in 1858 the widow and son settled at Pisa, where the latter attended the university. Soon afterwards they had to repair to Switzerland on account of Sara Nathan's republican sentiments; it was then that Ernesto Nathan became acquainted with Mazzini, whose views became thenceforth his chief inspiration and cult, and he devoted himself as a journalist, teacher and social reformer to their diffusion. A violent anti-clerical, he soon joined the freemasons and was elected " Grand Orient " for Italy in 1899, but resigned in 1905 owing to internal disagreements. He became an Italian citizen, and although he had been a republican in his early years, he gradually accepted the monarchy as the best *régime* for Italy, and ended by being received at Court. He showed great activity in organizing the " Unione dei Partiti popolari " in 1900, a *blocco* of the various radical and anti-clerical parties in Rome, and when at the municipal elections of 1900 the clerical administration fell, Nathan was chosen as mayor. That an English Jew and a militant anti-clerical and freemason should become mayor of Rome seemed indeed incongruous, but he was selected for his sterling honesty and business ability. Unfortunately he lost no occasion to offend Catholic sentiment and frequently made himself ridiculous, becoming a butt for the comic papers and *revues*. His plans for modernizing Rome did much to spoil its beauty for no useful purpose. Reëlected in 1910, he fell when the *blocco* broke up in 1913. On the outbreak of the World War, in spite of his 70 years, he volunteered for the army and actually served as a lieutenant of infantry for a time. In 1917 he was reëlected " Grand Orient " but resigned a year later. He was editor of the National edition of Mazzini's works.

**NATIONAL DEBT.**—The World War, 1914–1918, brought about a complete transformation in the size and composition of the world's national debts. Those of the belligerent countries were swollen to an enormous extent. The liabilities of the European nations were inflated to a degree which in the pre-war period would have been regarded as symptomatic of financial madness and world-wide collapse of credit. The British Prime Minister (Mr. Lloyd George), at the close of the war, estimated its cost at about 40,000 millions sterling, a figure which was accepted by a number of statisticians in Europe and America. Table I. is compiled from Paper No. IV on Public Finance, issued by the League of Nations for the International Financial Conference held at Brussels in the autumn of 1920. For purposes of comparison pre-war figures are also given, when they are available.

The increases shown in Table I., however, cannot be regarded as mathematically correct. Like is not compared with like; the unit of value has been changed in many cases, inconvertible paper currency having been made the legal measure of value in place of a definite weight of gold in all the belligerent countries except the United States and Japan. In order to make a proper comparison it is necessary to make a correction for the depreciation expressed in gold, in the value of money in the various countries. There is, however, no mathematical formula for making this correction, but the existence of a 20% discount in the gold value of the pound sterling (in May 1921) shows that the margin of error is a very material one. From the standpoint of national finance the importance of these national debt figures depends upon their ratio to national revenue. Ratios are shown in Table II., which expresses the debt as so many years' purchase of current revenue.

The countries are arranged in Table II. according to the post-war percentages. As the true burden of debt can only be determined by the relation which it bears to capacity to carry it, it follows that Table II. gives a truer picture of the world's national debt position in 1920 than Table I.

In the case of certain countries such as Austria, Hungary, Poland, and Russia, where the depreciation of the unit of value

*The high figure for Switzerland is mainly due to the fact that big loans were incurred by the Federal Government for railways.

reduced its gold value to an infinitesimal figure, the factor of correction is a very big one. The clearing of the financial wreckage of the war, the resumption of wealth production and exchange, must have the effect of raising the unit of value expressed in gold, and thus increase the burden of debt expressed in gold money and commodities. But this is true only of countries in which the depreciation of the unit of value was less serious. In 1921 it was quite impossible to indicate what countries would be able to restore the gold value of their currencies to the pre-war parity. The countries mentioned above, however, were clearly not in a position to restore the pre-war value of their currencies. In fact Austria in 1921 drew up a plan (at the instance of the League of Nations' Finance Committee) providing for the creation of a new unit of value. This, if applied, would have the effect of reducing the burden of debt expressed in gold and commodities, and would, of course, facilitate the revival of Austria's economic activities. The establishment of a legal standard of value of lower gold value than existed before the war must, of course, involve loss to the creditor parties in respect of all contracts made before the war, while on the other hand it must prevent the further enrichment of the *nouveaux riches* who had acquired their wealth during the war period in terms of a low unit of value. On the whole a greater measure of justice to the people of Austria might be rendered by the stabilization of the unit of value at a low figure than would be secured by attempting to raise it, since the great bulk of property in Austria came into the possession of its present owners at a price which fully expressed the depreciation of currency.

*British National Debt.*—Vast changes had been effected in the British national debt. The great bulk of the debt of the United Kingdom no longer in 1921 consisted of the (practically irredeemable) annuities known as "Consols." For the first time in the history of the British Empire it had been compelled to borrow extensively abroad during the war. The first foreign loan was issued in New York in 1915, the French and British Governments jointly and severally issuing a 5% five-year loan for $500,000,000 in Oct. of that year, the proceeds of which were divided equally between the two nations. This loan was repaid on maturity on Oct. 15 1920, and its repayment had the effect of strengthening American confidence in British national credit. Later, during the war, the British Government issued its own loans in New York; the first for $250,000,000 in two-year 5% bonds, which fell due on Sept. 1 1918, the second for $300,000,000 in three and five-year bonds bearing 5½% interest, which fell due in Nov. 1919 and 1921. The third was for $250,000,000 in one and two-year 5½% bonds, which fell due in Feb. 1918 and 1919. Collateral security was provided for all these loans mostly in the form of dollar bonds, which the British Government either bought or borrowed from its nationals under the Dollar Securities Mobilization Scheme. Other credits were raised in America, including a British banking credit, bearing 5% interest, for $50,000,000, which matured in June 1917; a credit of $25,000,000 for wheat purchases, which was paid off in 1917; and Treasury Bills for three months which were issued up to a maximum amount of $150,000,000 by Messrs. J. P. Morgan & Co., acting as agents for the British Treasury. Prior to the entry of the United States into the war on April 7 1917, Great Britain raised loans in America totalling $1,131,400,000. After that date the United States Government lent money freely to the British Government direct. An arrangement was made in 1919 by which interest payments on the Government loans were deferred for three years, namely, until 1922, and at the close of the year 1920 the total advances amounted to $4,196,818,000. Loans were raised in Argentina, Uruguay, Spain, Holland, Switzerland, Japan, Chile, and Sweden. The bulk of these were rapidly repaid, but the great bulk of Britain's debt to America still remained untouched in June 1921.

In two years from April 1 1919 the British external debt was reduced by £203,000,000; in the financial year ended March 31 1921 the reduction was £117,000,000. On that date the total was £1,161,560,000 at par of exchange. In the year 1920–21 the British debt to America was reduced by nearly £75,000,000, and the debt to Canada by £20,000,000. On March 31 1921 the only debt owed to foreign nations apart from the United States was £826,000 to Sweden. On the same date the British debt to Canada was $125,000,000.

The 5% War Loan issued at the beginning of 1917 had become the premier domestic British security, the old consols being now of an inconsiderable amount comparatively and relegated to the background in the market. Cash subscriptions to the loan had amounted to £966,048,000, and conversions (of the earlier 4½% Loan and Exchequer Bonds) amounted to £1,103,797,000, making a total of £2,069,845,000.

In December 1915 the principle of "continuous borrowing" was adopted for British Government war-borrowing. On the 17th of that month 5% Exchequer Bonds were put on sale, and realized, in the period which terminated on June 1 1916, £237,829,469. Four series of these bonds, the last series bearing 6% interest, were put on sale down to Dec. 30 1916, when the sales were temporarily suspended in preparation for the issue of the 5% War Loan, the greatest loan operation of the war. On April 13 1917 the daily sales of Exchequer Bonds were resumed, 5% Bonds being again offered at par. Sales of Exchequer Bonds, however, were brought definitely to an end on Sept. 22 1917 (partly because, by Statute, this form of issue was limited to a six-year term), and on Oct. 1 1917 a new type of security called National War Bonds, of a character more appropriate for the Government's requirements, was offered for day-by-day subscription, bearing 5% interest and redeemable at a premium varying from £2 to £5%, according to the maturity of the bonds, which ranged from 5 to 10 years. A great deal of energy was imparted to the campaign for selling these bonds, and it achieved marked success. Down to March 31 1918 sales of these bonds amounted to no less than £616,193,692. The second series, sold between April 1 1918 and Sept. 30 1918, produced £483,224,088; the third, between Oct. 1 1918 and Jan. 18 1919, yielded £494,399,505; and the fourth, between Feb. 1 1919 and May 31 1919, £75,745,151. "Continuous borrowing" amply justified all that was expected of it. By withdrawing from active circulation large amounts of currency the daily borrowing had the effect of holding commodity prices in check, the tendency of the latter being strongly upward on account of the continuous inflation of currency and credit involved by unceasing Government borrowing from the banks. During the war period investors showed a marked preference for short-dated securities, and the Government accordingly offered securities redeemable within a comparatively few years. But with the cessation of hostilities and diminution of expenditure the Government decided to make an attempt to issue a fairly long-term loan with the object of reducing the floating debt, which was then in the neighbourhood of 1,000 millions. On June 12 1919 it issued the first Funding Loan, bearing 4% interest and redeemable at the earliest in 1960, and at the latest in 1990. The bonds were offered at 80% and produced only

£215,200,000. At the same time the Government sold 4% Victory Bonds at 85%, subject to drawings at par almost immediately and acceptable at par in payment of death duties. These bonds produced £216,900,000. The failure of this operation compelled the Government to defer the question of funding any further portion of the floating debt (which rose to about 1,300 millions) for an indefinite period, especially as the demand for capital was exceedingly active, and funding could only be effected at a high cost, the Bank Rate being for over a year (from April 15 1920 to April 28 1921) 7 per cent. The approaching maturity of the short-term bonds issued during the war period, however, began to be a pressing problem in 1921, for the bonds, as they became very short, found their way to the banks and became potential floating debt. In April 1921 the Government decided to invite holders of 5% National War Bonds maturing in the years 1922 to 1925 to exchange their holdings for 3½% conversion stock. Holders were offered £160 to £163 of new stock for every £100 bond, giving a yield in interest of £5 12s. 0d. to £5 14s. 0d. per cent., against £5 7s. 6d. on the bonds held. About £632,000,000 of bonds were affected by the offer, and if the whole had been converted the addition to the State's liabilities would have amounted to about 400 millions, and the addition to interest charges about 4 millions per annum. Applications for conversion amounted, however, to only about 160 millions. In July 1921 a further effort was made to convert the very short term bonds into eight-year Treasury Bonds bearing 5½% interest. These bonds were offered at 97%.

When the British 5% Loan was issued in 1917 a 4% "tax compounded loan" was coupled with it. It was an effort to meet an insistent public demand for a Government security exempt from the heavy rate of income tax. Another way of meeting this same demand was attempted in some degree by a departure from the practice of paying dividends less tax. The 5% War Loan, National War Bonds, and the Funding Loan all contained a provision that dividends should be paid without deduction, and that tax should be collected upon it in the holder's annual return. The 4% Loan was not really a tax-free security. It was an issue, the interest on which was reduced to a figure which represented a compounding of income tax at the then maximum rate, namely, 5s. in the £1. The interest on the loan was not exempt from super-tax, and for the purpose of calculating liability to it, and also for the purpose of computing total income for purposes of exemption and abatement, it had to be assumed that the 4% interest was the net income after the deduction of income tax at the full normal rate of income tax prevailing. This meant that the holders of the 4% Loan were placed in about the same position as regards super-tax as holders of the 5% Loan, and in a worse position as regards exemption and abatement, for

TABLE III.—*Issues of British War Loans.*

| Issue | Amount of Issue | Price of Issue | Date of Issue | Cash credited to H.M. Exchequer |
|---|---|---|---|---|
| 3½% War Loan, 1925–28 | £350,000,000 | 95% | Nov. 17–24 1914 | £ 331,798,408 |

no claim to repayment of income tax was allowed in respect of the 4% Loan interest. At the time of issue the income derived from the 4% Loan was, for the purpose of super-tax, reckoned as £5 6s. 8d., or 1s. 5d. per cent. more than the income on the 5% Loan. In 1918, when the income tax was raised to 6s. in the pound, the holders of the 4% Loan, though exempt from the tax, found that for super-tax purposes their interest from the Loan was reckoned as £5 14s. 6d. per cent., while that on the 5% Loan remained at £5 5s. 3d. This shows that the terms of the tax compounded issue had been devised with much ingenuity. The right of conversion into any future War Loan which was attached to the 4½% Loan, floated in the middle of 1915, and also to subsequent issues of Exchequer Bonds, became operative in connexion with these two Loans, but it was considered inadvisable to attach a similar conversion option to the new loans. Instead, a device was adopted to achieve the same object, viz. protection of the loan against depreciation in price. The Treasury undertook to set aside monthly a sum equal to 1s. 8d. per cent. of each loan to be used in the purchase of stock for cancellation whenever the market price fell below the issue price, viz. 95 in the case of the 5% Loan and par in the case of the 4% Loan. Undoubtedly the operation of this fund contributed to the maintenance of the market price, but it wholly failed to prevent the stocks falling to a heavy discount, though about 30 millions were annually spent in the early years. In March 1918 an issue of nominative £5 bonds was made. Their chief distinction was the facility with which they could be purchased and sold. No filling of forms was required. The bonds could be bought like postage stamps, but they failed to become popular. The most successful means of raising money for the war from among small investors was by the issue of a security entitled War Savings Certificates (*see* SAVINGS MOVEMENT). This novel and important form of popular borrowing was introduced in Feb. 1916. The certificates were purchasable at post-offices, banks, and through Associations formed for the purpose of stimulating their sale. Subsequently they were placed on sale at shops and stores throughout the country. The certificates were issued at 15s. 6d. each, and could be paid for in instalments. They were repayable in 5 years from the date of purchase at £1; later, the period of maturity was extended to 10 years, and the redemption value raised to £1 6s. 0d. The increase of capital was equivalent to a yield of £5 4s. 7d. per cent. compound interest. This increase of capital was exempted from assessment to income tax, but no person was allowed to hold more than 500 at a time. Although these certificates were issued for a definite period, provision was made for their encashment at any time, but premature encashment was discouraged by the absence of any capital appreciation in the first year of their currency. But the certificates being repayable on demand at not less than the price at which they were issued, they could not depreciate in capital value like other marketable securities. A great development of propaganda methods took place in 1917, and more particularly in 1918, and resulted in a very great increase in subscriptions to Government securities. In Table III. are shown details of the various British War Loan issues, taken from a list drawn up by the Bank of England.

On March 31 1920 the British debt reached its highest total, namely, £7,829,000,000; on March 31 1921 it had fallen to £7,573,000,000. (C. J. M.)

**NATIONALIZATION.**—The fact that "Nationalization" had become in 1916–21 one of the burning political questions of the day is unfortunate as regards arriving at a clear appraisal of its principles, for, from the outset, it is difficult for a writer to avoid a certain bias in approaching its discussion. Yet Nationalization of some services and industries has been an accomplished fact for many years, without giving rise to any political controversy. In its narrow sense, Nationalization means taking over the ownership and control of an industry or service by the community, as opposed to ownership and control for the benefit of a person or a certain number of persons, be it in their individual capacity, or in corporate form in the shape of a company. The most familiar example of such a nationalized service in Great Britain and, indeed, practically every country is the Post Office.

The word Nationalization is, however, generally used to denote the principle of Public Ownership (to employ the much better term used throughout N. America) as opposed to that of private enterprise. For instance, in 1908, the three separate dock companies (one of them already an amalgamation of several companies) which owned and operated those undertakings in and around London were bought out, and ownership and management vested in a composite body known as the Port of London Authority, the Board of which is constituted as follows: seventeen members are elected by the payers of the dock dues; one by the wharfingers; four are selected by the Government (one representing Labour); two by the Corporation of the City of London, and two by the London County Council (one of them representing Labour). Strictly speaking, it would not be correct to say the Docks of London were "nationalized," for the taxpayers and ratepayers of Northumberland, for instance, are not in any way directly concerned with the undertaking, but the exploitation or the carrying on of the enterprise of the Docks of London has been converted from a number of private undertakings directed to the earning of profits for a certain number of proprietors, into a public undertaking the primary function of which is to render to the town of London, and the region dependent thereon, services connected with the provision of dock accommodation and of the things accessory thereto. This is not really Nationalization, but it embodies the principle meant by ninety-nine people out of every hundred who use the word, viz.: Public Ownership, be such ownership vested in a national authority, a municipal body or an *ad hoc* authority like the Mersey Docks and Harbour Board or the Metropolitan Water Board. It is, therefore, with this interpretation of Nationalization that we shall deal in this article.

*Relation to Socialism.*—A word must be said as to the relationship of Nationalization to Socialism. The two are by no means identical and although the nationalization of the means of production, distribution and exchange has long been a Socialist shibboleth, many modern Socialists oppose Nationalization as being merely "State Capitalism," a form of industry, they say, in which the workers might still be exploited for the benefit of those who control the national machine—probably the same governing classes as we now possess. The truth of the matter is that, although Nationalization is not Socialism, it is the most suitable economic machine whereby the aims of Socialism can be carried out, because, by eliminating the private *entrepreneur* and converting him into a *rentier* in receipt of fixed interest instead of being a participator in the profits, it removes one of the conflicting factors in industry, namely the owner, and reduces these factors to two, viz. the community in its dual capacity of owner and consumer, and all the workers in that industry.

It is the elimination of this private profit-making incentive which, in the minds of the advocates of Nationalization, is one of the principal arguments in its favour, and, in the minds of its opponents, is the chief argument against it. Nationalize industry, say the latter, and you do away with the desire of personal gain which is the dominant human motive leading to improvement, invention and efficiency; you stereotype existing conditions, you do away with competition and all the benefits arising therefrom, and you get wasteful management from a horde of Government officials who ride on the backs of the tax-payers.

Against this, the advocates of Nationalization urge that private enterprise, precisely because its dominant motive is personal gain, often fails to render the service that is its ostensible justification; it leads to adulteration, misdescription, and all sorts of chicanery, and while competition has its undoubted value as a stimulus to invention and new methods, our present system of industry does, of itself, run to amalgamations, absorptions and price agreements resulting in the abolition of real competition with its attendant advantages, so that we arrive at much the same result as if we had Nationalization, in the shape of monopoly, open or concealed, but with the profits arising from the elimination of real competition and the economies resulting from monopoly and unification going into the pockets of a small section of the community instead of being spread over the whole nation,

either in the shape of a better or cheaper service, or both; and that, even if our present imperfect Governments result in too many officials, it is no worse for the community that a certain number of persons (officials) with their families should be enjoying a decent livelihood out of the industry than that a number of other persons (*entrepreneurs* and large shareholders) should derive fortunes from the same industry. Further, they allege that no system of private enterprise combined with Government regulation (the usual suggestion for meeting a tendency towards monopoly) will be satisfactory, as it results in just that multiplicity of officials of the most uneconomic nature, in that they do not produce anything, that is the bugbear of State control.

It is not for us to determine here which view is right; and the former, the anti-nationalization view, is certainly that expressed most frequently in the columns of the Press. Be this as it may, it is an undoubted fact that throughout the whole world—in the United Kingdom as well as elsewhere—the principle of public ownership, unpopular as it appeared to be in many quarters, was in 1921 steadily gaining ground, and it may be useful if we consider some of the developments in this direction and endeavour to find some guiding principles which account for its growth.

*Factors making for Public Ownership.*—Prominent among these is the fear of combination among suppliers of services leading up to a monopoly, open or concealed, which, "human nature being what it is," inevitably results, sooner or later, in excessive prices being charged to the consumer. When this occurs, or tends to occur, in the case of a service vital to most sections of the community, a Government, however hostile its individual members may be to further extensions of public ownership, finds itself compelled to make a public service of it. It may itself assume a monopoly of such service, as in the case of Italy and Uruguay, both of which countries, early in the present century, had nationalized life insurance and made of it a national monopoly; more frequently, however, a Government in such circumstances starts a State-owned and operated service in competition with existing services, with the view of setting a standard of services and conditions and preventing prices from mounting beyond a reasonable basis. Coming under this head are the Commonwealth of Australia shipping line, the New Zealand and Queensland State Insurance Departments, the hundreds of publicly owned grain elevators that are to be found throughout Canada, and, in the United Kingdom, the Imperial Cable Service.

The Commonwealth Government line of steamers (*see* also SHIPPING) was started by the purchase in 1919 by the Australian Prime Minister (Mr. Hughes) of the Strath Line of 13 steamships, and some other vessels. The Australian Government gave it to be understood that it established the line as a means to a special end, viz. the protection of the Australian shippers and public from possible adverse results of recent amalgamations of private shipping interests, and not with any idea of driving the shipping companies out of the field. One of the abuses against which the institution of a State-owned mercantile fleet was aimed was the rebate system adopted by some of the big shipping lines, whereby shippers who forwarded goods by any line outside the combine had to pay higher freights, these being charged in the first instance and a rebate allowed only, provided that the said line received all their cargo. In an official circular issued by the Manager of the Commonwealth Government line of steamers appeared the following passages:—

"It is not the wish of the Commonwealth Government Line to originate a rate war. The freights charged are those current in the Australian trade at the time of shipment. Equal rates are quoted to all shippers, large or small, private firms or Government Departments, and in the event of a reduction taking place while a steamer is loading all shippers will benefit by it alike.

"A cash discount of 5 per cent. off the net freight is given to shippers on payment of accounts. *No primage is charged and no deferred rebate granted.* . . .

"In the event of shippers taking advantage of the services of this Line, and being penalized therefor by the confiscation of accrued rebates by any Line through which they have shipped previously, the Commonwealth Government Line is prepared to guarantee them against such loss, if they will sign the annexed undertaking to give the Line the first offer of their future business."

The Commonwealth Government actively continued the development of its shipping business, by the construction of 18 new steamers, with the result that in 1921 it had a fleet aggregating 444,000 tons.

The point that the principal aim of a State-owned competitive undertaking was to protect the public from overcharge, was brought out by the Lieutenant-Governor of Queensland at the opening of the Queensland Parliament in August 1920 when, referring to the State Insurance Department, he said:—

"While not intended to be revenue-producing, this office has since its inception shown a profit averaging over £60,000 per annum, and has at the same time saved many thousands of pounds to the insuring public. . . . Through the State entering into competition with fire insurance companies reductions in premiums ranging from 25 per cent. to 33 per cent. have been effected in favour of policy holders, which means approximately a saving of £20,000 to those who pay fire insurance premiums."

In the case of the Imperial cable which links the United Kingdom with Canada, West Indies and Australasia, the chief factor in building up a State-owned system was the value for political and defensive purposes of having a cable wholly under British control, and in its advertisements the Post Office boasted that "the Imperial Cable is Government owned and is the only Atlantic cable under purely British control." While the rates charged for ordinary telegrams were the same as for those sent by other Atlantic routes, the official advertisements stated:—

"It is the only Atlantic route on which the deferred service at reduced rates has been restored. A deferred telegram to Montreal and other places in Eastern Canada costs 4d. a word: to Jamaica 1s. 3d. a word: to New Zealand 1s. 4d. a word: to Australia 1s. 6d. a word."

Here we have the case of a nationalized service affording more facilities than its privately owned competitor.

Another motive for the provision by the State of a service hitherto performed by private enterprise is that of protecting persons against the dishonesty of individuals in the shape of malversation of trust funds. As in many similar directions, New Zealand was the pioneer in appointing a public trustee, but in 1908, despite active hostility on the part of the legal profession, such an office was opened in the United Kingdom.

Its purpose was described in the official pamphlet published by the Public Trustee Office as follows:—

"The Public Trustee Act, 1906, was passed with the express object of enabling the public to guard against the risks and inconveniences incidental to the employment of private individuals in trust matters, and it substitutes for them a trustee who will never die, never leave the country, and never become incapacitated, and whose responsibility is guaranteed by the Consolidated Fund of the United Kingdom."

Extensive use was made of this nationalized service, which exists in competition with professional people and companies performing the same functions (*see* PUBLIC TRUSTEE).

Yet another circumstance which drives State or municipal authorities into public ownership is the fact that certain public needs exist which are not filled by private enterprise on account of their not fulfilling the first condition of private enterprise, viz. profit. It is this incentive, rather than those already referred to as governing Australia's action in acquiring shipping, that caused Britain, the United States and Canada during the war to build and operate State-owned merchant fleets. With the disappearance of the emergency created by the war, the British Government rapidly disposed of its merchant ships to private owners, and its action in this respect was in 1921 apparently being followed by the United States Government.

For the same reason as that already mentioned, viz. the failure of private enterprise to supply the need, the national authority has in many countries had to arrange for the construction of houses and to let them at uneconomic rents.

Sometimes a Government finds itself compelled to nationalize an undertaking by reason of the fact that a privately owned concern of public utility fails financially and, if the State did not take it over, would become derelict. From this cause the Canadian Government has of late years found itself constrained to become the owner of the greater part of the railroads in the Dominion, the only other railroad owner of importance (but of very great

importance) being the Canadian Pacific Railway Company. It requires no great stretch of imagination to picture the same development with the railways of the United Kingdom.

A perhaps less meritorious motive that causes many Governments to nationalize a service or industry is that of acquiring revenue thereby. When this occurs, the State undertaking is invariably made a monopoly, and is as much a means of indirect taxation as it is a business undertaking. Nationalized services of this description have hitherto been much rarer in the United Kingdom, as compared with other countries, although they are common enough in India and the British Crown Colonies. In India the working and sale of salt, in the Straits Settlements the sale of tin, and in many countries the manufacture and sale of tobacco in every shape and form are State monopolies, from which large profits are made or derived.

Services having to do primarily with the health and wellbeing of the whole community show a decided tendency towards public ownership. The sewerage systems of most countries are in the hands of public authorities, and in several departments of activity relating to the health and wellbeing of the community, one can see in operation throughout the world the transition stage from private to public ownership, both systems working side by side, but with an invariable tendency on the part of the publicly owned service to grow, not merely by the establishment of additional institutions, but by the absorption of privately owned undertakings. This process is steadily in operation in England in connexion with such services as asylums, hospitals, cemeteries and water-works, whilst education is rapidly being transformed from a private into a publicly owned industry. The growth of these public services is not confined in England to the provision of services imposed upon municipal authorities by law; for example, municipally owned lunatic asylums now make provision for private paying patients, and are made use of to an increasing extent, so that the private asylum is gradually dying out.

Another class of undertaking which is becoming more and more publicly owned is the service which is essential to the whole community or at least to most sections thereof. First and foremost comes the transmission of correspondence through the post-office, the most familiar form of nationalized undertaking. When one bears in mind the fact that the nationalized British post-office is the largest multiple shop concern in that country, having a branch in every village, it can readily be seen that such a network of Government shops lends itself most easily to an extension of duties. How convenient such a network of Government shops may be to meet a sudden emergency is shown by the duties placed upon the post-office at short or no notice during the war. When it was decided to collect from the nation magazines and books for distribution to the troops at the various fronts, it sufficed merely to notify the public that it could hand such publications over the counter at any post-office. In their capacity of Government shops, the post-offices of the United Kingdom, within 1908–21, had taken on additional work involved by the following new services:—

Payment of Old Age Pensions.
Payment of Army and Navy Allowances.
Sale and Encashment of Saving Certificates.
Sale of Government Loan Bonds.
Sale of National Health and Unemployment Stamps.
Sale of Entertainment Stamps.
Sale of Income Tax Stamps.

Nor are these new services all side-lines of small account; in hundreds of offices the actual sale of health and unemployment insurance stamps exceed the sale of postage stamps. With the increased tendency towards social legislation, there is little doubt that the services performed by means of the comprehensive post-office organization in every country will inevitably be extended still further. In the United Kingdom the Union of Post Office Workers had for some time before 1921 been carrying on an agitation for the provision of new facilities for the public which are in operation in other countries, such as the introduction of the postal cheque and transfer system, dispatch of parcels on the cash-on-delivery system, the collection of bills and subscriptions, etc. This agitation is worth noting by students of Nationalization, as indicative of fields of activity for trade unions composed of workers in a nationalized undertaking, additional to those concerned merely with their own betterment.

There are, however, other services which, being essential to all or most sections of the community, are gradually coming to be recognized as due to be transferred from the realm of private profit-making to that of public service. In most countries railway and canal transport are regarded as naturally falling within this category, and not a year passes without numerous water, gas and electricity undertakings in all parts of the world being transferred from companies to municipal bodies.

In the working out of the problem that has for some time been engaging the attention of engineers, of the most economical large-scale production and distribution of energy or power, the trend has been inevitably towards public ownership. The largest generator and distributor of hydro-electric power in the world was, in 1921, the Hydro-Electric Power Commission of Ontario, a publicly owned body formed on a coöperative basis by city and rural municipalities, through which the province of Ontario generated through hydro-electric energy over 95% of the total consumption of power within its borders from all sources. The Australian Government Morwell Power scheme will supply electricity to the greater part of Victoria, and in Sweden and Switzerland the respective Governments are developing electricity from water-power on a very large scale. In fact, throughout the world, almost all the great developments in this direction were in 1921 being carried out by, or on behalf of, Governments or municipal authorities, or combinations of both.

At first sight it might appear possible to draw a line of demarcation between these services which naturally fall within the sphere of public ownership and those which belong to the realm of private enterprise; but this is not so simple as it looks. It is easy to say that the community should carry on non-profit-making undertakings like the roads, sewers and public conveniences, leaving all other services, out of which profits can be made, to private enterprise, which, with the aforesaid profit-making incentive, is likely to give more facilities and be more receptive to new ideas. But it is only custom which makes us regard the provision of a drainage system, the collection of refuse, etc., as a non-profit-making service. In Rosario, the second most populous city in the Argentine Republic, and in Valparaiso, the second largest city of Chile, the drains belong to, and are operated by, the Rosario Drainage Company, and the Valparaiso (Chile) Drainage Company, respectively, both English companies. In Paris and Brussels limited companies make the business of supplying public conveniences pay handsomely.

Another argument might be that, as water, gas, electricity and tramway services cannot be carried on without disturbance to the publicly owned roads and bridges, it is natural that these undertakings should be owned by the same authority as is responsible for the roads. This might explain the fact that, gradually, such undertakings are becoming nationalized or municipalized, but one is constrained to ask why the roads and bridges themselves should be publicly owned; they were not always so, and practically every municipality now makes a monetary loss on bridges which at one time, under private enterprise, produced good profits to their owners.

Many people would agree that services directly connected with the health of the community should be carried on as public undertakings without regard to profit, *e.g.* isolation and general hospitals, ambulance services, sewers, extinction of fires and saving of lives in connection therewith. But here again it is difficult to draw a definite line of demarcation. If sewers are vital to the health of a city, so also is a supply of pure milk; and the extension of public ownership along this direction is shown by the fact that the town of Sheffield, since November 1918, has municipalized its milk supply, and its example was in 1921 likely to be followed by other British cities.

*State Leases.*—There is an intermediate form of Nationalization or public ownership which to a considerable extent bridges the gulf between those who consider that all services and industries vital to the community should be carried on by the community.

and those who consider that Nationalization or public ownership leads to wasteful and bureaucratic methods and the disappearance of enterprise. This *via media* lies in the direction of the State or municipality owning an undertaking, but leasing it to a company under a concession for a fixed term of years, on a profit-sharing basis. The State or municipality, as representing the community, has control or a deciding voice in matters of principle, conditions of labour, etc., whilst the concessionaire company has the customary incentive to commercial efficiency. At the end of the concession the State or municipality is free to take over a complete service that has been organized on a commercial basis, or to grant a fresh concession. This system is becoming increasingly popular throughout the world, and appears preferable to the composite bodies, composed of municipalities and joint-stock companies, hitherto favoured in England.

*Nationalization of Industries.*—Detailed nationalization schemes for three separate industries in Great Britain had already been published by 1921, covering mines, railways and land respectively. That for mines was prepared in 1919 on behalf of the Miners' Federation of Great Britain, that for railways was prepared on behalf of the Railway Nationalization Society, and that for land was based upon an original draft made by the present writer for the Land Nationalization Society. The three schemes approximate more nearly to one another than might have been anticipated, having regard to the difference between the three services of coal mining, railway transport, and land ownership. Each provides for administration by a national council, appointed as to part by the Government and part by the workers engaged in the industry, with a Cabinet Minister at the head.

The miners' nationalization scheme (which covers coal and ironstone, shale, fire clay and limestone, but excludes sandstone, granite, slate, chalk, building clay, gravel and sand) provides for a National Mining Council consisting of a President and 20 members, 10 of whom are to be appointed by the Government, and 10 by the Miners' Federation.

The railway scheme provides for a National Transport Council consisting of the Minister for Transport, 3 persons nominated respectively by the Minister for Transport, the Board of Trade and the Treasury, and 3 representatives of the railway workers selected by the Transport Ministry from a panel of not less than 12 persons nominated annually for that purpose by the several committees of the 20 principal trade unions of which the membership is drawn wholly or in great part from persons engaged in the services of transport. This more complex method of providing for representatives of the workers in a nationalized transport system is due to the fact that, whilst practically all the workers in and about coal-mines are members of units making up the Miners' Federation of Great Britain, workers on the railways alone, apart from other branches of transport, are spread over a large number of trade unions. It will be further noticed that while the miners' scheme imposes upon the Minister for Mines ten members of the council definitely selected by the Miners' Federation, the railway scheme gives the Transport Minister some latitude of choice, by giving him powers of selection from a panel. This scheme not merely overcomes the difficulty of having to deal with a number of trade unions, but also enables the Minister to select as colleagues those on the panel with whom he considers he can best work, or who seem the most suitable.

In the case of land ownership—a totally distinct matter from the working of the land—there is no large body of workers which may justly claim representation on the management, and here representation of the various sectional interests has been aimed at by providing that the National Land Council should consist of the Minister for Lands; three members appointed by him, the Ministry of Health and the Ministry of Food respectively; one appointed by the Minister for Lands from a panel of not less than three persons nominated for the purpose by representatives of Farmers' Unions and Chambers of Agriculture; one appointed by the Minister from a panel of not less than three persons nominated by Associations of Smallholders and Allotment holders; and one appointed by the Minister from a panel of not less than three persons nominated by Agricultural Labourers' Unions.

In all three schemes provision is made for local or district councils, to which the National Council may delegate such powers as it thinks fit. The constitution of these district councils is analogous to that of the national councils, the proportion of workers' representation being the same, and in the case of the mines, provision is made also for the formation of councils for the separate pits. Members of all the councils are to receive such remuneration as the National Council, with the consent of the Treasury, may determine. The miners' scheme allows for the formation of a council to represent the interests of consumers, but such council has no executive powers and is purely advisory. In the case of the transport and land schemes no such provision is made, it being assumed that the members of the council nominated by the Government do, *ipso facto*, represent the general community, which in this case constitutes the consumer.

Another nationalization scheme for the coal industry was sketched by Mr. Justice Sankey, the Chairman of the Coal Industries Commission, 1919. This scheme provides for national ownership and, like the miners' scheme, aims at avoiding too bureaucratic a management by handing over the administration to district councils. While, however, the miners' scheme makes the National Mining Council of which the Minister of Mines is a member, the supreme authority, the Sankey scheme leaves the Minister of Mines in supreme control, with the obligation to consult the standing committee of the Mining Council on certain questions. Whereas the composition of the joint bodies in the miners' scheme is dual, representation being divided between the Government and the miners, in the Sankey scheme, it is tripartite, one-third representing the workers, one-third the consumers and one-third the technical and commercial side of the industry; the Government is not represented at all on this body, but, as stated, the Minister of Mines is not obliged to carry out recommendations of the National Mining Council, although that body is to meet regularly "for the purpose of superintending the operation of District Mining Councils."

All three schemes provide for compensation to the owners for the properties to be nationalized, and for payment to be made in Government stock bearing the rate of interest current at the time on that existing Government stock which most nearly approximates in length of time and conditions to the stock contemplated under the scheme. That is to say, if British Government 5% War Loan is quoted at a price at which it yields 5½%, the stock issued in payment of the properties taken by the State is to be on the basis of 5½% at par, it being immaterial from this point of view, whether in payment of a property worth £100, the owner receives £100 of 5½% stock or £110 of 5% stock. In deciding the amount to be paid for each property acquired, there arises the thorny question of the basis of value and compensation. The miners' scheme provides for the appointment of ten commissioners for this special purpose, three of them to be nominated by the Miners' Federation and three of them by the owners' organization, the Mining Association. If a majority of commissioners cannot agree as to the purchase price of any property, the chairman (appointed by the Government) shall have power to determine the value. A coal-mine is to be valued on the average actual annual number of tons actually raised during the five years prior to August 4 1914, due regard being paid to the actual gross and net profits during that period and to the amount set aside for depreciation, renewals or development, to the probable life of the mine, and to the condition in which it is. Where a mine has not been fully developed, the amount which would be raised under full development without any increase of capital expenditure is to be taken as the average annual number of tons. The scheme, however, fixes a maximum purchase price, viz.:—

| | Per ton s. d. |
|---|---|
| When 100,000 tons or less have been raised per annum on the average during such five preceding years, a capital sum equal to one such year's output at . . . . . | 12 0 |
| When more than 100,000 tons have been raised per annum on the average during such five preceding years, a capital sum equal to one such year's output at . . . . . | 10 0 |

In the case of the railway nationalization scheme, the purchase price is to be a sum equal to the mean between the highest and lowest officially quoted price of each stock during the first 12 of the 18 months preceding the introduction of the bill, the idea of a buffer of six months being to prevent prices being forced up on the basis of stock quotations being made known.

In a Railway Nationalization bill issued in 1921 by two of the trade unions representing the railway workers, and sponsored by the Labour party, the price to be paid differs from that contemplated in the Railway Nationalization Society's scheme, on which the Labour party bill was largely based, in that the mean quotation of each stock during the year 1913 shall be taken as the basis, but shall be "subject to a reduction relative to the amount by which securities generally have depreciated in value in consequence of the war." This agrees with the policy under which the three Government Committees appointed to report upon State control of the Drink Trade unanimously recommended state purchase on the following basis:—

"The profits to be so capitalized must be pre-war profits, and the effect of war conditions on profits whether favourable or the reverse, must be excluded."

The draft railway nationalization bill referred to suggests that this reduction on the 1913 stock exchange value should be in the neighbourhood of 30%, even that being less than the fall that has occurred on other investment stocks of the same description.

The land nationalization scheme puts forward two alternative bases for purchase, viz.:—

(*a*) Twenty times the rateable value of the property as existing at Dec. 31 1918, and, where no rateable value exists, the value put upon the property by the land valuation of 1910; or

(*b*) The value put upon the property by the valuation of 1910, and in any cases where such valuation shall not have been completed, it shall be valued on precisely analogous lines so as to make the value the same as if it had been fixed under the 1910 valuation.

In the case of the land being let on lease, the compensation is to be divided between the landowner and the leaseholder in proportions determined by an *ad hoc* tribunal.

The Government stocks to be issued in payment of the properties nationalized are all redeemable at par—in the case of the railway and land schemes by means of a sinking fund of ·5%, sufficient to redeem the entire loan within approximately 50 years, while in the case of the miners' scheme, no statutory sinking fund is provided, but net profits are to be applied to that purpose. Each scheme provides for the drawing up of separate accounts, showing fully the results of the year's operations, to be submitted annually to Parliament and there discussed.

*Management.*—There is no doubt that the principal problem in connection with Nationalization or Public Ownership lies in the direction of efficient management. The traditions of British Government Departments, which have been concerned primarily with the administration of legislative enactments and not with the management of trading concerns, is not conducive to efficiency as the business man understands it. This, however, applies more to national than to local government officials, the latter being in closer contact with the people for whom they act, and being more accustomed to act in an executive capacity. Mr. Justice Sankey in his Coal Industry Commission Report (Cmd 210), dated June 20 1919, wrote:—

"The Civil Servant has not been trained to run an industry, but the war has demonstrated the potentiality of the existence of a new class of men (whether already in the service of the State or not) who are just as keen to serve the State as they are to serve a private employer and who have been shown to possess the qualities of courage in taking initiative necessary for the running of an industry.

"Hitherto, State management of industries has on balance failed to prove itself free from serious short-comings, but these short-comings are largely due to the neglect of the State to train those who are to be called on for knowledge and ability in management.

"The experience of the last few years has, however, shown that it is not really difficult for the British nation to provide a class of administrative officers who combine the strongest sense of public duty with the greatest energy and capacity for initiative. Those who have this kind of training appear to be capable in a high degree of assuming responsibility and also of getting on with the men whom they have to direct."

The need for a wider training and the creation of a new type of Government official to carry on publicly owned undertakings is now fully realized, and the newer universities and such institutions as the London School of Economics are turning out men and women suitably equipped in a technical sense to carry on such services as will be taken over by the community. Moreover, as each service is taken over, so is the existing staff who, themselves, naturally carry on to a great extent the traditions of the service whilst under ordinary commercial management.

In conclusion, it may be said that the immediate future trend of Nationalization or Public Ownership would appear to be in the direction of internal services of public utility or health, rather than industries calling for trading abroad, and while all prophecy is dangerous, a survey of world tendencies leads to the conclusion that those industries which will gradually come to be publicly owned, be it nationally or municipally, will be found among the following: transport, insurance, banking, coal and oil, electricity and power generally, housing, liquor trade, tobacco. Where such a service or industry has a large foreign trade, *e.g.* coal, it may well be that the State will grant a concession to a company to carry on that particular department of the industry on a profit-sharing basis. Of the continued growth of the principle of public ownership there can be little doubt.

AUTHORITIES.—The three nationalization bills for Mines, Railways and Land are printed *in extenso* in *The Case for Nationalisation*, by A. Emil Davies (Allen & Unwin, 1920). **NAVAL HISTORY OF THE WAR.**—The tornado of war which broke upon the world in 1914 found the British navy at its post and ready for action. A review of all the seaworthy vessels of the fleet had taken the place of the customary annual manoeuvres, and by July 23 the ships had already begun to disperse. By the 26th the whole outlook had grown dark. The German Emperor was hastening back to Berlin, and Admiralty orders were sent by the First Sea Lord (Adml. Prince Louis of Battenberg[1]) to Adml. Sir George Callaghan to remain with his First Fleet at Portland, and to the ships of the Second Fleet to be ready near their crews at their home ports. Squadrons abroad were warned of the political tension, and on the 27th the commander-in-chief Mediterranean was told to concentrate at Malta. On the 28th Austria issued her declaration of war, and orders went out at 5 P.M. for the First Fleet to leave for its war base at Scapa Flow. It sailed at 7 A.M. on the 29th.

The British fleet at the time consisted of the Home Fleet and the squadrons on the various stations abroad (Mediterranean, East Indies, China, Australia, Cape, N. America and West Indies and S.E. coast of America), but the bulk of it was to be found in the Home Fleet. This fleet was divided into three categories in three successive stages of efficiency. The First Fleet (to be designated the Grand Fleet) comprised all the newest ships fully manned, and in permanent commission. The Second Fleet consisted of older but still efficient battleships and cruisers with nucleus crews amounting to two-fifths of their complement aboard. Last of all came the Third Fleet, a rather motley collection of obsolescent but serviceable ships in the basins of our naval ports with only a small "care and maintenance" party aboard. The constitution of these fleets is summarized in Table A, and it will be seen that practically the whole of the "dreadnought" strength of the fleet was concentrated in Home Waters.

Tables A and B shown in terms of units were the two forces

[1] Later created Marquess of Milford Haven (d. 1921). This last service to Great Britain by one who had always been a fine naval officer was never forgotten, although he retired soon after rather than allow his German origin to compromise his position.

ranged against one another across the North Sea. In terms of gun-power the British fleet was decidedly superior; 13 of the British dreadnoughts were armed with 13·5 guns and the others with 12 in., while the Germans had 12-in. guns in only nine of their ships and 11 in. in the remainder.

On July 29, the day that the British Home (or First) Fleet left for the north, the First Lord (Mr. Winston Churchill) pressed the Cabinet for the initiation of the Precautionary Period, and the warning telegram went out to all squadrons abroad. By Aug. 1 the tension had increased. Germany had issued her ultimatum to Russia and had declared *Kriegsgefahr*. In Hamburg British ships were being detained. Immediately this news arrived the Admiralty issued orders at 2:15 P.M. to act on the instructions for mobilization, but the reserves were not yet called out. Late that night the news came in that Germany had declared war on Russia, and at 1:25 A.M. on Aug. 2 the Admiralty issued the order to mobilize. By 4 A.M. on Aug. 3 the whole fleet stood mobilized and ready for action.

The German mobilization had taken a somewhat different course. Arrangements had been made for the fleet to visit various ports in Norway, but on July 15, when the cruise commenced, the German Admiral Staff was already beginning to doubt the wisdom of its continuance. By July 23 the Kaiser had adopted the view that the fleet should be recalled, but the Chancellor was loth to do anything to aggravate the current tension and proposed to wait and see what England did. But no sooner had Adml. von Ingenohl anchored in Sognefiord on July 25 and opened his mails than he became deeply impressed with the gravity of the situation. He went straight to the Kaiser and persuaded him to let the fleet sail for its home ports. It got under way on the 26th, and at 7 P.M. on July 27 had assembled off Stavanger. On the 30th the German ambassador at St. James's sent word that Sir Edward Grey had told him that the British fleet had sailed for the north of Scotland. Strained relations were notified to all commanders-in-chief that day, and on the 31st at 5 P.M. the telegram for *Kriegsgefahr* (Precautionary Period) went out. Everything was now hastening downhill. War was declared with Russia on Aug. 1. The 2nd and 3rd Squadrons came round from Kiel to the North Sea the same day and at 8 P.M. that evening the order to mobilize went out.

One important step had not been taken. The German Admiral Staff had asked for orders to be issued for armed merchantmen to proceed to the trade routes, but the Chancellor had demurred and only one proceeded to sea. Before any more could sail the British Grand Fleet was at its post and actually put to sea on the morning of Aug. 4 to circumvent movements of this sort.

Its old commander, Adml. Sir George Callaghan, was no longer with it. It was thought that a younger commander was required to face the heavy responsibilities of war. By 8:30 A.M. Sir George Callaghan had struck his flag, and the fleet put to sea on Aug. 4 under its new commander, Sir John Jellicoe. That night at 11 P.M. the eventful order went out to all ships and squadrons "Commence hostilities at once against Germany."

The Grand Fleet, for so it was to be designated, was already at sea engaged in a sweep to the south-east. These sweeps were an essential feature of the British war plans, which were primarily based on the concentration of the main fleet in the north to guard the northern exit of the North Sea. The closure of the southern exit was to be effected by flotillas supported by older squadrons and by the use of mines.

By its mere concentration at the outlets of the North Sea the British fleet performed all its principal tasks. It covered the trade routes, cut off Germany from the ocean, protected the coast line against invasion and secured the transport of the army. Further afield the focal and terminal areas of trade were guarded by cruiser squadrons. The protection of the coast was entrusted to patrol flotillas, under the Admiral of Patrols (8th Flotilla in Forth, 9th Flotilla in Tyne, 7th Flotilla in Humber, 6th Flotilla at Dover). This strategy was simple and effective. It offered ample opportunities for offensive tactics, survived the whole war and was justified by the course of events.

The plans embodying it were only prepared in the latter part of 1913, and differed materially from those of the previous decade, which had favoured large landing operations on the German coast. The whole coastline of Great Britain stood behind the British plans, stretching like a colossal breakwater across Germany's path to the sea, and reproducing the geographical conditions of the Dutch wars.

This breakwater was 500 m. long. From the Shetlands to Norway (Sumburgh Head to Udsire) was 190 m., a distance well within the compass of a strong fleet. Dover Straits was only 21 m. wide, and though the concentration of the main fleet at Scapa 500 m. away left it exposed to attack, any British force south of 56° (*i.e.* the latitude of the Forth) threatened the flank of a force attacking the Channel, and Germany never actually took the risk of such a venture with any of her big ships.

So long as the enemy refrained from an attack in force, the dispatch of British troops across the Channel was almost as easy as sending them to Ireland or across the Thames. The length of the principal route from Southampton to Havre was only 100 m., and the average time of transport only 13 hours. No transport was, therefore, ever more than seven hours from port. The route was over 100 m. west of Dover Straits, and in these circumstances the whole transport system could be quickly and rapidly controlled.

But Dover remained the weak point of the war plans, and all the more so as the actual organization of the southern area was defective. In the north there was one command. In the south there were five, namely, the Channel Fleet, the Dover Patrol, Cruiser Force C, the Harwich flotillas and Commodore (S). There can be little doubt that a determined attack in this area at the beginning of the war would have severely shaken the whole fabric of British strategy, but the enemy never attempted it. British troops poured in a continuous procession across the Channel. With the exception of the "Goeben" and "Breslau" in the Mediterranean there was nothing to threaten the safety of the Channel to the westward, and on Aug. 10 this anxiety was removed by the news that the "Goeben," after a strange chapter of accidents, had entered the Dardanelles the evening before. (*See* GOEBEN AND BRESLAU.)

Germany's strategy was defensive. This was forced on her by her inferior strength and unfavourable position. It was based on the idea that the British fleet would enter the Bight, where it was hoped to wear it down by ruthless minelaying and submarine warfare. Then when the British fleet had been reduced to reasonable proportions and when an equilibrium of strength (the greatly desired *Kräfteausgleich*) had been attained, a decisive battle would be dared. First a policy of waiting, of sorties and attrition, then a decisive action. This was the substance of the German operation orders for the North Sea.

*Movements during 1914.*—In pursuance of these aims, at 8:30 P.M. on Aug. 4, an hour after orders to prepare for war with England went out, the "Königin Luise" of the Hamburg American Line was despatched to lay mines off the Thames. She fulfilled her task but never returned. While Jellicoe was carrying out his sweep in the north Comm. Tyrwhitt with the "Amethyst" and "Amphion" and the Harwich flotillas carried out a similar operation in the south. About 10 A.M. on the 5th the "Königin Luise" was sighted on her way back, and the "Lance" and "Landrail" followed hot on her trail. She could go only 21 knots, and was quickly overhauled and sunk about 50 m. east (true) from Lowestoft. But she had laid her mines off Aldeburgh, and the "Amphion" returning ran on one of them and went down in a few minutes with a loss of 150 men. This threat to the North Sea routes emphasized the necessity of minesweeping, and started the enormous expansion of that important service which became one of the principal features of the war (*see* MINELAYING).

Meanwhile the Germans had seen nothing of the British fleet, and on Aug. 6 10 German submarines, escorted for 100 m. by the "Hamburg" and "Stettin," went off into the North Sea to look for it, with orders to remain on the line between Stavanger and Scapa Flow till 6 P.M. on the 10th. Their first cruise was not particularly successful. A torpedo was fired at

the "Monarch" and missed, U15 was rammed by the "Birmingham" (58° 26′ N. 1°58′ E.), and U13 never returned. But the operation had an important bearing, for though reassuring enough from one point of view it gave the British commander-in-chief a sense of insecurity, and he asked permission to take the fleet to the west of the Orkneys as soon as the Expeditionary Force was across. That night (at 10 P.M. on the 6th) he received orders to take his whole force north-west of the Orkneys. The menace of the submarine was already working when the transports were assembling to take British troops over to France.

On Aug. 5 the British Government had decided to send the Expeditionary Force across the Channel, and Aug. 9 was finally fixed as the first day of passage. The question of transporting a British Expeditionary Force across the sea had been a subject of study for some years. Southampton to Havre was the principal route for troops, Newhaven to Boulogne for stores, and transports were already assembling at Southampton. It had been part of the war plans that, in the event of troops being sent to France, the Grand Fleet was to come down to a position south of the Forth (latitude 56° N.). But it was now to westward of the Orkneys, and remained north of Cromarty (58° N.) till Aug. 15, sometimes west of the Orkneys and sometimes east. The task of immediate protection fell therefore to the Channel Fleet. By Aug. 9 its 18 ships had assembled off Portland and were covering the lines of passage in the Channel. In the Narrows between Holland and Harwich, Tyrwhitt had a watching patrol of 12 to 18 destroyers on a 30-m. front. The "Bacchante," "Cressy," "Hogue," and "Aboukir" of Cruiser Force C were behind him in the Downs or off Dungeness keeping touch with the Channel Fleet. In the Straits were five destroyers of the Dover Patrol (increased to 12 at night) assisted by three light cruisers, and supported by 10 submarines of Comm. Keyes' force posted between the Goodwins and Ruytingen (near Calais). French submarines were on watch between Gris Nez and the Varne, and far to the westward cruising from Ushant to Land's End was Rear-Admi. Rouyer's force of 14 old French cruisers in touch with Wemyss' squadron of four "Talbots." This was a respectable force, and was in position by the 9th when the troops began to cross, and for a fortnight remained on the alert. A steady stream of transports passed across the Channel, sailing as soon as they were ready and waiting only for the tide. Their numbers rose to 44 on the 14th, and remained well over 30 per day up to Aug. 18. On Aug. 12 the Admiralty suggested to the commander-in-chief that the fleet should return to the eastward of the Orkneys, and it came back just when the flow of troops was at its height, and sweeping down to the latitude of the Forth (56° N.) on the 16th joined hands with the southern forces, and for a few hours made a complete ring round the German Bight. But nothing was seen of the enemy and the Grand Fleet returned to Scapa. It arrived there on the 18th, and the enemy for the first time ventured out a little way. Two light German cruisers, the "Stralsund" and "Strassburg," pushed into the Narrows that day. There they were sighted at 6:30 A.M. by the "Fearless," which gave chase and opened fire on the "Strassburg" (thought to be the "Rostock"). Tyrwhitt came hurrying to the scene followed by Cruiser Force C, and the enemy quickly decamped.

By the 20th four British divisions had crossed, but the news from France was bad and another division was hurried over. By Aug. 23 the movement was complete. Out of 240 transports employed not one had been lost by accident or enemy attack. A hundred thousand men were in France, and British divisions were already fighting against heavy odds at Mons.

In order to secure the position in the south and on the east coast, a squadron (Cruiser Force K) of two battle-cruisers, the "New Zealand" and "Invincible," under Rear-Admi. Sir Archibald Moore, was now stationed in the Humber and remained there for a time. Hardly had the passage been accomplished and the Watching Patrol been withdrawn for a short time than news came of a severe check in France, and the Admiralty was faced with the possibility of having to abandon the French Channel ports. So far did matters go that Boulogne was closed down on Aug. 24 and the army base was shifted to St. Nazaire. This would have meant a serious dislocation of British naval strategy, but before it reached a critical stage the German advance had been checked.

The retention of Ostend and the Belgian coast was now engaging naval attention. Marines were being hurried over there, and for nearly two days (from Aug. 26–28) the Channel Fleet and Cruiser Force C were carrying them and their stores across, and were lying off Ostend to support their landing. The operation was entirely abortive. No sooner had they been landed than they were reëmbarked. The landing offered an excellent opening for the German High Sea Fleet to attack, but for a time at least its attention was riveted to the Bight.

Commodore Keyes' submarines had been watching the German patrols round Heligoland for some time, and on the strength of their observations he had suggested a plan for cutting them off. The original orders provided only for a concerted operation by six of Comm. Keyes' submarines, and Tyrwhitt's flotillas supported by the five "Bacchantes" of Cruiser Force C and the "Invincible" and "New Zealand." But at the last moment Beatty and his battle-cruiser squadron were fortunately allowed to join in, and there followed on Aug. 28 Beatty and Tyrwhitt's dramatic swoop into the Bight (*see* HELIGOLAND BIGHT). The German patrols were driven in, the big ships failed to support them, and three light cruisers, the "Mainz," "Ariadne" and "Cöln" were sunk.

The action had an important ulterior effect. It confirmed the Kaiser, probably influenced at the time by the situation in E. Prussia and the Baltic, in his determination to follow a strictly defensive naval policy, though Tirpitz fought strenuously for an increased offensive.

German strategy now settled down to the two-fold form of submarine activity against ships-of-war and minelaying, varied by occasional raids against the English coast. The activity of the German submarines (or "U-boats") soon began to be felt. On Sept. 5 U21 entered the Forth and sank the "Pathfinder," a light cruiser patrolling outside, the first ship to fall a victim to an enemy submarine. Scapa's defenceless state became a source of acute anxiety to the British commander-in-chief, and the Grand Fleet itself was not immune from false alarms, which in the circumstances had to be taken seriously enough. On Sept. 1 the "Falmouth" thought she saw a submarine, and there ensued a feverish commotion in the Flow, which culminated in the battle-fleets weighing in thick weather and putting to sea at night. It anchored in Loch Ewe and was there on Sept. 7 when it was recalled to the North Sea to screen the passage of the 7th Division. Again Beatty's squadron and Tyrwhitt's flotillas swept the Bight from east to west on Sept. 10 with the battle-fleet behind them, but this time it was bare.

A week later (Sept. 17) an important conference assembled in the "Iron Duke's" cabin at Loch Ewe. The First Lord (Mr. Winston Churchill) was there with the chief of the war staff (Rear-Admi. Doveton Sturdee) and the Director of the Intelligence Division. Weighty matters were discussed, and the remains of the old war plans emerged in the form of a proposal to attack Heligoland and to enter the Baltic. It was decided that the former project offered no advantage, for when it was taken it could not be held, and that no operation on a large scale could be attempted in the Baltic without endangering British supremacy in the North Sea.

When the First Lord returned he found the German threat to the Belgian and French Channel ports beginning to develop, and orders went out on Sept. 19 for the Marine Brigade to be landed at Dunkirk as the nucleus of a larger force. The task of screening their passage fell on the southern forces. This was one of the functions specially allotted to them in the war plans, and it came as a severe shock to the Admiralty to find Cruiser Force C, one of its component squadrons, suddenly swept off the board. On Sept. 22, while patrolling at 10 knots off the Dutch coast, the "Cressy," "Hogue" and "Aboukir" were torpedoed between 6:25 and 7:30 A.M. by U9, and disappeared beneath the waves with a loss of 60 officers and some 1,400 men. This

exploit produced a profound impression on both sides of the North Sea. It was the first striking success of the German submarine. For the moment something had to be found to cover the proposed operations on the Belgian coast, and it was decided to lay mines in the Narrows. The idea was no new one. It had been part of the British war plans in 1913, but the plans had outrun the performance, for the mines available at the outbreak of war required new pistols and new mooring-ropes, and could not be laid in the positions indicated on account of the tide. This had been pointed out in May 1914, and the work was now taken seriously in hand. A large area was notified on Oct. 2, and three lines of mines were laid between the Downs and Holland, but unfortunately the design of the mines was defective and their real utility small.

The commander-in-chief had hardly been informed of this new policy when on Oct. 2 he was ordered to take special measures to ensure the safety of the Canadian convoy, which was on its way across. For eight days a special watch was established, with the whole fleet stretching right across the waters between Fair I. and Norway. The convoy consisted of 31 ships, escorted by Adml. Wemyss and Cruiser Force G right across the Atlantic. The battle-cruiser "Princess Royal" went out into the Atlantic to meet it, and she and the old battleship "Majestic" brought it safely in to Plymouth on Oct. 14. The battle-fleet had retired, but the 10th Cruiser Squadron was still patrolling the next day at 10 A.M. on a line between Peterhead and the Naze 10 m. apart, when the "Hawke," which had stopped to get her mails from the "Endymion," and was going on again at 12 or 13 knots, was struck by a torpedo from U9. There was only time to lower two seaboats, and 500 lives were lost as she sank.

The losses were not all on the British side. The British submarine E9 (Lt.-Comm. Max Horton), lying off Heligoland, had sunk the small cruiser "Hela" on Sept. 12, and now one of the German minelaying enterprises came to a sudden and disastrous end. Four German destroyers of the 7th Torpedo Half Flotilla (S115, S116, S117, S119) left the Ems in the morning of Oct. 17 to lay mines off the North Foreland, but the "Undaunted" with some of the British 3rd Flotilla ("Lennox," "Lance," "Legion," and "Loyal") was waiting for them in the Narrows, and after a chase and sharp fight the last German boat sank off the Texel at 4:30 P.M. The success came very happily, for the guns were again busy on the Belgian coast. Dover had now became a separate command under Rear-Adml. the Hon. Horace Hood. A great German attack was gathering against Nieuport, and Joffre had asked on Oct. 16 for naval guns to act against the German right. Hood's light craft hurried across, followed by the monitors, and for nearly a week they maintained a heavy fire over the sand dunes against the German flank.

While the "Lennox" and "Lance" were sending their last shots into the German boats the British destroyers in the north were again engaged in a feverish hunt over the Flow. In the afternoon of Oct. 16 a German submarine was reported close to Switha Sound on the west side of the main entrance. Again the fleet had to raise steam and get to sea that night. There can be little doubt that these alarms were false, but they serve as a reminder that the British preparations for war were far from complete. The menace of the submarine had been recognized in 1912, and arrangements could have been devised for rapidly defending harbours by means of mines and booms. But the British mines were defective, and no suitable booms had been designed. The commander-in-chief proceeded to sea, and in view of the defenceless state of Scapa decided to take the fleet to Lough Swilly. Its arrival there on Oct. 22 meant a serious dislocation of the war plans, which were beginning to give way both in the north and south through the pressure of the German submarine. The proper reply, booms and a supply of efficient mines, had not been foreseen and was not forthcoming.

Oct. 1914 saw the sudden dispatch of the R.N. Division to Antwerp, and the landing of forces at Dunkirk and on the Belgian coast. The defence of Antwerp was a military and not a naval problem, but the extension of the transport routes to the Belgian coast and the landing of the 7th Division at Zeebrugge on Oct. 7 represented a considerable expansion of the original war plans, and brought a heavy strain on the Dover Patrol. The old battleship "Venerable" joined Rear-Adml. Hood's force, and lent the Belgian army the support of her guns in the German attack on Nieuport, which culminated on Nov. 2, when they fell back from the Yser as the waters rose.

On Oct. 27, when the Nieuport sluices were being opened, a bad piece of news arrived. The move to Lough Swilly had proved singularly unfortunate. Two days before the battle-fleet left Scapa, the "Berlin," a large Norddeutscher Lloyd of 17,000 tons, had left on a minelaying cruise, and laid mines on Oct. 23 some 26 m. north-west of Lough Swilly in the north of Ireland. On the 27th the "Audacious" going out to battle practice struck one of them, though she remained afloat for some hours. The White Star liner "Olympic," outward bound full of passengers, came up and tried to tow her, but found her unmanageable. At 9 P.M. she was still 15 m. from Lough Swilly when she settled, sank and blew up. With the Grand Fleet 300 m. from the North Sea, the whole groundwork of the British war plans was giving way, and the commander-in-chief left to confer with the Admiralty. It was a new board he met. Prince Louis of Battenberg (Marquess of Milford Haven) had resigned, and Lord Fisher had stepped into his place.

It was decided that the 3rd Battle Squadron of King Edward's should leave the Grand Fleet and reinforce the Channel Fleet, thus securing the situation in the south. Nowhere did naval activity on the part of the enemy seem so likely as off the Belgian coast, where a small number of old British ships were fighting, 1,000 m. from the Grand Fleet at Lough Swilly, and barely 300 m. from the Bight. To secure the approach to Dover and the Belgian coast it was decided to lay mines in the North Sea, which was declared a military area on Nov. 2. The notification was hardly issued when news came in on Nov. 3 of a German raid on the east coast. This was made by the battle-cruisers "Seydlitz," "Moltke," "Von der Tann," "Blücher," the armoured cruiser "Yorck," and three light cruisers, with the object of covering the light cruiser "Kolberg" in laying a minefield some 15 m. from Yarmouth. Commodore (T), whose flotillas were patrolling in the Narrows, sent them off in chase. The Admiralty thought the raid was a prelude to something bigger, and ordered the Grand Fleet to proceed to Scapa and Beatty to put to sea, but by 4 P.M. the Germans were well on their way home and the orders to the Grand Fleet and Beatty were cancelled. The Germans did not get home scot-free. The "Yorck" struck a mine off the Jade and sank.

The commotion had barely died down when early in the morning of Nov. 4 a telegram arrived from the British consul-general at Valparaiso with news of Coronel (*see* CORONEL). Cradock's squadron had been wiped off the board, and the whole system of trade defence began to tremble under the menace of von Spee's approach. This marks a milestone in the war. Steps were instantly taken to retrieve the situation; but to understand it we must leave home waters for a time.

*Cruiser Warfare, 1914.*—Outside home waters the principal task of the British navy was the protection of trade, and cruiser squadrons were stationed for this purpose at the focal points of maritime traffic, a system which may be termed the "Squadron" or "Patrol" system as compared with the "Convoy" system adopted later against the submarine. The number of German cruisers abroad was comparatively small. The largest squadron was von Spee's, consisting of the armoured cruisers "Scharnhorst" and "Gneisenau" (each 8 8·2-in., 8 5·9-in., 20½ knots), and the light cruisers "Emden," "Nürnberg" and "Leipzig," which threatened China, Australia and the East Indies, and gave rise to reactions which were felt over the whole world. In the East Indies was the "Königsberg," a German light cruiser with 10 4·1-in. guns, able to steam 22 or 23 knots, and in the Atlantic the "Dresden" and "Karlsruhe," armed with 12 4·1-in., and with a full seagoing speed of 25 to 26 knots. This completes the tale of German cruisers abroad.

As soon as war broke out the introduction of a Government

Insurance Scheme had a great steadying influence on British trade, but over all the four seas the Admiralty was confronted with the problem of reconciling the squadron system, which was intended to hunt down enemy cruisers, with insistent demands for convoy which could not be denied. These demands arose all over the world, for a great imperial concentration was bringing the legions of the Dominions home at the very time when an attack on the German oversea possessions was sending them farther afield. In the east the convoys from India absorbed the whole of the East Indies Squadron; in the west the Canadian convoy in Oct. 1914 took away Rear-Adml. Wemyss and all his four cruisers (Force G) from the mouth of the English Channel. The expeditions to New Guinea and Samoa monopolized the whole Australian Squadron for a time. The Cape, Cameroon, and British East Africa all made similar demands on the squadrons, and the system was constantly threatening to break down.

When war broke out the "Karlsruhe" had just relieved the "Dresden," and both were still in the West Indies. In New York, too, were several fast German merchant cruisers, but the "Kronprinz Wilhelm" was the only one which actually put to sea. On Aug. 6 the "Suffolk" (Cradock's flagship) came suddenly on the "Karlsruhe" arming the "Kronprinz Wilhelm," some 120 m. N.E. of Watling I. (off Cuba), but after a long chase and an action in the moonlight with the "Bristol" the "Karlsruhe" got away. Then came news of her and the "Dresden" to the southward, and on Aug. 22 Cradock, who had transferred his flag to the "Good Hope," went off after them and began his fateful journey to the south. The "Karlsruhe" remained in the West Indies and South Atlantic. The "Kaiser Wilhelm der Grosse," which had succeeded in slipping out of the North Sea on Aug. 5, was trying to get in touch with her, but on Aug. 26 was caught by the British cruiser "Highflyer" (Capt. Henry T. Buller), coaling at Rio del Ore, a desolate anchorage on the Sahara coast, and after a short action was sunk. The "Karlsruhe" (Capt. Kohler) continued to disturb British trade for some months, and had sunk 15 ships up to Nov. 4, when she suddenly blew up in the West Indies, leaving the survivors to get home to Kiel in the "Rio Negro."

The depredations of the "Karlsruhe" and "Dresden" led to Rear-Adml. Sir Christopher Cradock being appointed in command on the south-east coast of America on Sept. 3. He was given the three armoured cruisers "Good Hope," "Monmouth," and "Berwick," the light cruisers "Glasgow" and "Bristol," and the armed merchantmen "Otranto," "Carmania" and "Macedonia." Then ensued a hunt down the coast for the "Dresden." The "Carmania" (Capt. Noel Grant) went off to Trinidada, a tiny islet 600 m. out in the South Atlantic, and, though she did not find the "Dresden," she came upon an armed merchantman, the "Cap Trafalgar," coaling there on Sept. 14. An action ensued, the "Cap Trafalgar" was sunk and the "Carmania" limped back to Gibraltar to repair damages. Meanwhile the "Dresden" (Capt. Lüdecke) had been joined by the German s.s. "Baden" with 13,000 tons of English coal, and had coaled at the Rocas Is. and Trinidada. Then with the "Baden" and "Santa Isabel" she sped southward to a little harbour, Orange Bay, hidden among the glaciers of Hoste I. in the vicinity of Cape Horn. There she lay from Sept. 5–16 before she ventured into the Pacific. In the Atlantic she had sunk only two ships, and allowed five to go on. Cradock was still on the south-east coast. The menace of von Spee had begun to loom in the west, and the British armoured cruiser "Defence" (Troubridge's late flagship) had been ordered to join him from the Mediterranean, but was detained there with defects.

Von Spee had been last located at Ponape in the Carolines on Aug. 9, and on Sept. 15 a message arrived from the Admiralty definitely informing Cradock, then at Santa Caterina (Brazil), that there was strong probability of the German squadron proceeding to Magellan, and that the "Defence" and "Canopus" were being sent to him. He was to concentrate a squadron strong enough to meet von Spee, then search Magellan Straits, break up German trade and destroy the German cruisers. The fact that his force could only muster 2 9·2-in. against von Spee's 16 8·2-in. was apparently lost sight of. Hardly had the telegram been sent than another followed on Sept. 16 to say that von Spee had appeared off Samoa on Sept. 14, that the situation had changed, Cradock need no longer concentrate his cruisers, and German trade on the W. coast was to be attacked at once. This second telegram was the beginning of a chapter of misfortunes, and its motives remain obscure. The situation had indeed changed, but in a sense precisely opposite to that intended. Concentration and reënforcement were more necessary than ever, but someone had apparently become obsessed with the idea that von Spee was making for North America (apparently on the sole ground of his very commonplace ruse of steering N.W. when he left Samoa), and the Admiralty abandoned their original opinion that he was making for Magellan. The order for the "Defence" to proceed to the S.E. coast was cancelled, though Cradock was not even informed of this, and remained under the impression that she was on her way out to reinforce him. For another reason Sept. 15 is a red-letter day in the story of cruiser warfare, for on it the news arrived of the German cruiser "Emden's" incursion into the Bay of Bengal, which immediately reacted on the China and Australian squadrons.

Von Spee's memorable journey can only be described here in the briefest terms of place and time. When war broke out he was at Ponape, the German capital of the western Carolines. Thence he went to Pagan in the Mariana Is., where he was met by the "Emden" and a dozen supply ships, the latter leaving for her great venture in the East Indies on Aug. 14. Thence the squadron proceeded eastward to Enivetok, another atoll in the Marshall Is.; then on to Majuro in the same group, arriving on Aug. 26. There von Spee had heard (probably by wireless via Honolulu and Nauru) of Japan's entry into the war, and abandoned all thought of return. His next port of call was Christmas I., a small islet right in the middle of the Pacific, where he arrived on Sept. 7. On his way he had heard of the capture of Samoa, and after coaling at Christmas I., proceeded on Sept. 9 straight to Samoa, where he arrived at 3 A.M. on Sept. 14, hoping to surprise a British naval force there, but found the harbour empty. A landing was out of the question, and he withdrew. The report of his visit went out by wireless to Suva in Fiji, and thence by cable to New Zealand and London. The squadrons directly and immediately affected by the news, besides Cradock's, were the China and Australian, for in China it left Adml. Jerram free to hunt the "Emden" down, and in Australia it relieved Adml. Patey's mind as to the expedition to New Guinea and the homeward-bound Australian convoy.

A short survey of events on these two stations will now be given. In China Rear-Adml. Jerram's effective force consisted of the old battleship "Triumph," the armoured cruisers "Minotaur" (4 9·2-in., 10 7·5-in.) and "Hampshire" (4 7·5-in., 6 6-in.), and the light cruiser "Yarmouth" (8 6-in.). Japan's entry into the war on Aug. 23 secured the China seas, and Rear-Adml. Jerram took his force south, to bar any attempt on the part of von Spee to break back into the East Indies. The Admiralty ordered him on Aug. 23 to proceed in search of the "Scharnhorst" and "Gneisenau," and keep in touch with Rear-Adml. Patey in Australia, but there was no news of von Spee, and accordingly on his arrival at Singapore on Aug. 30 the British admiral sent his cruisers to search the Dutch East Indies, where 22 German merchant ships had taken refuge. This search lasted till Sept. 13, but already demands for convoys were beginning to dislocate his plans. On Sept. 8 the Admiralty ordered him to send the "Minotaur" and "Hampshire" to meet the Australian convoy, due to leave Fremantle for Europe on Oct. 3. The commander-in-chief decided to send the "Minotaur" in the meantime with two Japanese ships, the "Ibuki" (4 12-in., 8 8-in.) and "Chikama" (8 6-in.), to Rabaul in New Britain, to cover Australia, when suddenly the situation was changed on Sept. 15 by the news of von Spee's appearance at Samoa, and more imperatively by the simultaneous appearance of the "Emden" in the Bay of Bengal. Till the "Emden" was finally run down by the "Sydney" at Cocos I. on Nov. 9 the

China Squadron was almost wholly engaged in her pursuit in the East Indies. The station boundaries had entirely broken down under the stress of war.

In Australia the same influences had been at work. At the outbreak of war Rear-Adml. Patey had decided to take up a position at Port Moresby in the Gulf of Papua, covering Australian waters and not too far from the enemy's two principal harbours, Rabaul (or Simpsonhafen) in New Britain and Friedrich Wilhelmshaven in New Guinea. Like the commander-in-chief on the China station he thought rightly that it was useless to search in the spaces of the Pacific for an unlocated enemy, but in his case demands for convoy began even sooner to dislocate his plans. New Zealand's expedition to Samoa was ready on Aug. 18 and the Admiralty approved of its starting, telling Patey on Aug. 13 to give it naval support. But he was at sea at the time with poor wireless connexion, and only received news of the expedition on Aug. 16. No sooner had he arranged to meet it with the battle-cruiser "Australia" and the cruiser "Melbourne" 450 m. south of Fiji on Aug. 24, than the Australia Navy Board complicated matters by asking that their New Guinea expedition should be taken first. Finally it was decided to take it second, and that the "Sydney" in the meantime should take the New Guinea force as far as the Barrier Reef and then wait for the "Australia" and "Melbourne" to return from Samoa. The "Australia" arrived at Samoa on Aug. 29, the force was landed, the British flag hoisted and she left the next day to join the New Guinea force. But now the demands of the European convoy came cranking in and upset Patey's plans. On Sept. 3 the Admiralty ordered the "Melbourne" and "Sydney" to be detached for it, and on Sept. 10 asked for the "Australia" as well. She was then engaged with Patey in the New Guinea operations. Rabaul was occupied on Sept. 13 but German forces still remained active, and Patey, not liking to leave, suggested that the China squadron should help in a search for von Spee. Then on Sept. 15 came the important news of von Spee's appearance at Samoa, clearing up the situation. The "Australia" and "Montcalm" were left to cover the New Guinea operations while the "Sydney" joined the "Minotaur" and "Ibuki" to escort the Australian troops to Europe and to cause the "Emden's" destruction.

While these events were happening in Australia and the East Indies, Cradock had gone on to the southward, and by Sept. 28 his ships were in the Magellan Straits, searching the gorges of Tierra del Fuego. On Oct. 3 the "Glasgow" and "Monmouth" went on to the W. coast in accordance with the Admiralty telegram of Sept. 16, but the "Good Hope" remained in the Falklands area, waiting for the "Canopus." Von Spee had been reported off Tahiti in the Society Is. on Sept. 22, and on Oct. 5 was again located by an intercepted wireless to the "Dresden," which stated that he was on the way to Easter Island. No shadow of doubt could remain that he was on his way across, and the Admiralty sent word to Cradock to be prepared to meet him, adding that the "Canopus" should accompany the "Glasgow" and "Monmouth" and "Otranto" in their search. It was not a practicable idea. The "Canopus" could go only 12 knots, and the conception of a cruiser squadron relying for its safety on a slow old battleship was both tactically and strategically unsound.

Cradock received the message on Oct. 7 1914, and on the 8th sent a message to say he was concentrating at the Falklands, and suggesting the formation of a strong second squadron on the E. coast to intercept the German squadron if it should succeed in evading him. The telegram reached the Admiralty on the 11th, and steps were immediately taken to carry out the Admiral's proposal by the dispatch of the "Defence" and "Kent" to reinforce Adml. Stoddart on the E. coast. The First Lord (Mr. Winston Churchill) was also in favour of postponing Cradock's cruise to the W. coast, but the reply actually sent to him merely took the form of a concurrence in the "concentration" of his vessels "for combined operations." The concentration at the Falklands never materialised. The "Good Hope" left for the W. coast (via Cape Horn) on Oct. 22, leaving the "Canopus" to follow with her colliers (via Magellan). Cradock's intentions will never be precisely known. He probably felt it incumbent on him to support the "Glasgow" and "Monmouth." There was a vagueness at both ends of the wire. Cradock spoke of concentrating at the Falklands when half his squadron had already been sent to the W. coast. The Admiralty expressed their concurrence in his concentration there for combined operations (whatever that might mean). But their readiness to reinforce Stoddart at Cradock's suggestion indicates that they would have been equally ready to reinforce Cradock himself if he had pressed for it. But neither in his telegrams nor in his letter of Oct. 12 did he suggest, much less definitely state, that his squadron was too weak to face the foe. There was one vessel which could have saved the situation, namely the "Australia," if Cradock had been told to wait for her, but she had been retained off Fiji to guard against von Spee's possible return, and was left there straining on her leash.

Von Spee was now at Mas-a-fuera (Oct. 18–26), a small island 450 m. from the coast of Chile, and the two squadrons were approaching one another, for Cradock had joined the "Glasgow," "Monmouth" and "Otranto" at Vallenar in the Chonos Archipelago on Oct. 27. The two forces met off Coronel towards evening on Nov. 1. The battle had been von Spee's for over a month. Cradock's flag, still flying gloriously, went down into the Pacific. The "Monmouth" sank with the "Good Hope." The "Glasgow" and "Otranto" got away. The "Canopus" was 300 m. off, toiling northward at 12 knots (*see* CORONEL).

The news arrived in England in the morning of Nov. 4, and fell on the country like a thunderclap. Lord Fisher was now First Sea Lord and every effort was made to redeem the situation. The battle-cruisers "Invincible" and "Inflexible" were taken from the Grand Fleet, and sailed on Nov. 11, with Vice-Adml. Sir Doveton Sturdee, late chief of the war staff, in command. Rear-Adml. Stoddart waited for him at Abrolhos Rocks with the "Carnarvon," "Cornwall," "Defence," and "Kent." The West Indies Squadron went off to watch the Panama Canal. Von Spee meanwhile had visited Valparaiso, and, unaware of the thunderbolt launched at him, was on his way southward. The "Canopus" had returned to the Falklands and was organizing the defences there.

Adml. Sturdee coaled at Abrolhos Rocks, and rushed on with his ships ("Inflexible," "Invincible," "Carnarvon," "Cornwall," "Kent," "Glasgow," "Bristol," and "Orama") to the south, arriving at Port Stanley, Falklands, in the forenoon of Dec. 7. Meanwhile the "Australia" had been unleashed, and was speeding across the Pacific, and a Japanese squadron had moved down to Fiji to take her place. Von Spee had passed the Horn in bad weather at midnight on Dec. 1. The next day his squadron met a three-masted Scottish barque, the "Drummuir," with 2,800 tons of coal on board, and put back into Picton I., near Beagle Channel, to transfer her coal. On Dec. 6 the work was finished. The "Drummuir" was sunk, and with her sank von Spee's hopes of getting home. He had decided at Picton I. to make a raid on the Falklands. On Dec. 8 1914 at dawn the islands were in sight, and the "Gneisenau" and "Nürnberg" were sent in towards Port Stanley. In the battle which followed (*see* FALKLAND ISLANDS BATTLE) the "Scharnhorst," "Gneisenau," "Leipzig" and "Nürnberg" were sunk, and von Spee and his two sons perished. The battle stands out as one of the great beacons of the war at sea, for it marked the collapse of German naval power beyond the seas.

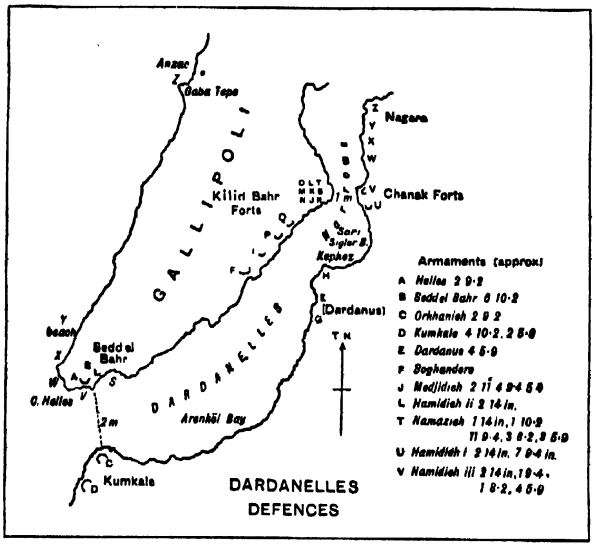
The "Emden's" career in the East Indies had already come to an end, with a tale of 15 ships. She had ranged the Bay of Bengal from Sept. 7–25, bombarded Madras on Sept. 22, worked in the approaches to Colombo till Oct. 21, coaling in the Maldives and at Diego Garcia, and raided Penang on Oct. 28. The "Hampshire" and "Chikuma," "Empress of Asia" and "Yarmouth," had searched for her in vain, though the latter on Oct. 9 had sunk her two supply ships at Pulo Tapak on the west coast of Sumatra. At dawn on Nov. 9 she appeared off the cable station at Cocos Keeling I., and the operator flashed the

news to Singapore. The big Australian and New Zealand convoy of 38 transports homeward bound, which left Albany on Nov. 1, escorted by the "Minotaur," "Melbourne," "Sydney," and "Ibuki," was approaching Cocos. It was only 55 m. off when the news reached it, and the "Sydney" went off to Cocos I. at full speed. An action ensued between the "Sydney" (Capt. J. C. Glossop, 8 6-in.) and the "Emden" (Capt. von Muller, 10 4·1-in.). By 11:30 the latter was driven ashore, blazing.

With the destruction of von Spee's squadron there remained only, as regards German naval forces at sea, the "Dresden" hiding in the creeks of Tierra del Fuego, and the "Königsberg" shut up in the Rufiji river (German East Africa), both of them powerless for harm. The ocean passages were again secure for Great Britain and her Allies. Samoa and New Guinea had fallen, and a Japanese guard stood at the gates of Tsingtau. In Cameroon, Duala, Buea, and Victoria had been occupied. The naval operations under the conduct of Capt. C. M. Fuller had contributed largely to this success, and the "Cumberland" now joined the stream of British cruisers homeward bound.

*Operations in 1915.*—The year 1915 saw a heavy blow dealt at the German battle-cruisers in the North Sea. An impression prevailed in Germany at this time that the British fleet was preparing to block the Jade and it was decided to send Rear-Adml. Hipper's battle-cruisers as far as the Dogger Bank to reconnoitre on Jan. 24, but the Admiralty had intelligence of this and dispatched Beatty with his battle-cruisers on the 23rd to join hands with Tyrwhitt. They met Hipper's forces on the morning of Jan. 24 and the battle of the Dogger Bank ensued in which the Germans lost the "Blücher" and were driven back to port (*see* 30.848). The battle reacted at once on German naval strategy. Von Pohl, chief of the staff, replaced von Ingenohl in command of the High Sea Fleet with instructions to use extreme caution. The successes of von Weddingen had inclined the German naval staff more and more to submarine warfare which opened with the declaration of a war zone round the British Isles on Feb. 4. Their tendency in this direction was strengthened by the final collapse of their cruiser warfare abroad. News of the "Dresden's" destruction arrived in March 1915. For two months after the battle of the Falklands she had lain hidden in the innermost recesses of the Magellan Straits with half a dozen British cruisers looking for her, and it was not till Feb. that she ventured to creep back into the Pacific in order to meet a German collier south of Juan Fernandez. The "Kent," searching the Barbara Channel (Magellan Straits) with the "Glasgow" at the time, got the news and hastened after her. On March 7 1915 she reached the rendezvous but the "Dresden's" speed enabled her to get away. It was not for long, however. The "Glasgow" had made out the words "Juan Fernandez" in a message the "Dresden" had sent and there, on March 14, the "Kent," "Glasgow" and "Orama" found her and brought her career to an end.

From the lonely islets of the Pacific we must return to Europe for a time. There the centre of interest had shifted from the Grand Fleet to the Dardanelles. After the Dogger Bank action the German fleet became more wary in its excursions and the work of the Grand Fleet was confined to periodical cruises enlivened only by an occasional attack by a submarine. The battle of the Falklands had released a number of older battleships and cruisers but in the North Sea the war was settling down into a state of equilibrium. The Germans rarely came out of the Bight and we could rarely go into it. On sea and land a deadlock had arisen, giving rise to the belief that a better outlet for energy could be found in the Mid East. In this way the idea of the Dardanelles came cranking across the original plans of naval strategy, challenging even the Grand Fleet in its insistency, swallowing at a gulp the Channel Fleet and wrecking Lord Fisher's plans for a Baltic campaign.



The general conception was sound for it was a matter of first-rate importance to gain free access to Russia and the scheme offered strategic political and economic advantages of the first magnitude, but it was begun in a haphazard way and its direction was marred by an inability to distinguish clearly between a naval bombardment and a combined naval and military operation and by a failure to appreciate that two operations unless conducted simultaneously must prejudice one another. The history of the naval side of the subject can only be briefly sketched. Petrograd had asked on Jan. 2 for a diversion to relieve the pressure of the Turks in the Caucasus. The idea of the Dardanelles was broached. Vice-Adml. Sackville Carden, the senior officer in the Mediterranean, gave his opinion on Jan. 11 that a progressive attack on the defences, step by step, was practicable. The First Lord (Mr. Winston Churchill) waxed enthusiastic over it and pictured the forts falling in succession before the "Queen Elizabeth's" guns. There can be little doubt that had plans and preparations for a combined operation been made on a sufficient scale, a great success might have been gained; but the refusal of Lord Kitchener to supply the troops led to the proposal to force the Straits with ships alone. This was an entirely different operation and the war staff failed to put its difficulties in a clear enough light. It was and is a truism of naval warfare that ships are handicapped in engaging forts. A ship cannot be concealed; a fort, and much more a modern movable battery, can. Aerial reconnaissance and the increased range of naval guns were supposed to have altered these conditions, but aerial spotting in conjunction with naval artillery was still in its infancy, and the limitations of naval bombardment were insufficiently appreciated.

The First Lord had a wofully extravagant estimate of the capacity of the "Queen Elizabeth's" guns, and thought of her creeping relentlessly forward, destroying each fort in turn with five or six 15-in. shells. Lord Fisher was absorbed in his project for a campaign in the Baltic, and it was allowed that the proposition was worth a trial.

The result was an endeavour to perform a task of first-class magnitude with second-class material and with insufficient preparation. Had a force for the purpose been segregated and thoroughly trained on the lines afterwards followed for the much smaller project of Zeebrugge, the chances of success would have been much greater. It would have required a nucleus of the best artillerists, the best minesweeping officers and the best minesweeping vessels in the fleet and at least two score of first-class airmen to evolve and apply a sound scheme of air-spotting. Given these necessary adjuncts and approximately six weeks of intensive specialized training to groin the whole into a solid arch, the Dardanelles could probably have been forced. But here the strategical weakness of the conception would have revealed itself. The forcing of the Straits in itself could do little unless it precipitated a revolution. In default of a revolution the fleet would have been left in the air in the Sea of Marmora, for its ships could hardly pass and repass through a channel a mile wide whose shores were in hostile hands. But the principal objection lay in the fact that any premature bombardment must inevitably wreck or at least imperil the prospects of a combined operation and anticipate surprise where surprise was the essence of success.

But by Feb. 1915 the idea of merging the two operations had crept in. A military force was to be available "to reap the fruits" and was being assembled in Egypt. The opinion found favour that if the navy failed, the army should help—a fatal conception which ignored the real relativity of the two operations. Meanwhile Lord Fisher's attitude of lukewarm acquiescence had changed to one of definite disapproval, but his position was weakened by his adherence to a scheme for landing in the Baltic, much more difficult and dangerous. The War Council definitely approved of the project on Jan. 28, bringing Lord Fisher to the verge of resignation.

The force collected for the purpose consisted of the "Queen Elizabeth" (Capt. George Hope) and "Inflexible" (Capt. R. Phillimore) with a heterogeneous collection of old battleships drawn from the Channel Fleet or which had come home from abroad after von Spee's defeat. In command was Vice-Adml. Sackville Carden who had been admiral superintendent at Malta Dockyard when the war broke out, with Comdr. Roger Keyes as his chief-of-staff. Operations against the outer fort

were begun at 8 A.M. Feb. 19 by the "Inflexible" (8 12-in.), "Agamemnon" (Capt. H. Fyler 4 12-in., 10 9·2-in.), "Cornwallis," "Vengeance" (both 4 12-in., 12 6-in.), "Triumph" (Capt. Maurice Fitzmaurice 4 10-in., 10 7·6-in.), "Bouvet" (2 12-in., 2 10·8-in.), "Suffren" (4 12-in., 10 6·4) and "Gaulois" (4 12-in., 10 5·5-in.). The forts were apparently silenced, but when the ships closed in at 2:45 P.M. reopened fire, and were still firing on the Asiatic side when failing light put a stop to the operations. On Feb. 25 the operations were resumed with better results. The "Queen Elizabeth" (8 15-in.) assisted by the "Agamemnon" put both guns of Cape Helles out of action and the "Vengeance" (Capt. Bertram Smith) and "Cornwallis" (Capt. Alex. Davidson), running in, engaged it at close range. The Kumkale forts on the Asiatic side were silenced by the "Irresistible" (Capt. Douglas Dent), "Gaulois," "Suffren" and "Charlemagne," and by 5:15 P.M. all the outer forts were effectually reduced. The minesweepers proceeded in and swept a channel four miles up. The entrance was now clear and the "Albion" (Capt. Algernon Heneage), "Majestic" (Capt. H. F. Talbot) and "Vengeance" entered on Feb. 26 and engaged Fort Dardanus (E) on the right-hand side halfway up to the Narrows. But the outer forts were merely the outworks of the defences. The real obstacle loomed ahead at the Narrows, where a channel only a mile wide was commanded by a score of batteries, mounting at least 9 14-in. guns and three times as many 10-in. and 9-in.

March 3 to March 17 was occupied with attempts to sweep the channel by night and reduce the forts by day. On March 3 the "Irresistible," "Albion," "Prince George" (Capt. Alex. Campbell) (all 4 12-in., 12 6-in.) and "Triumph" resumed the attack on Fort E and the sweeping operations continued. It was here, however, that the principal shortcomings arose. The minesweeping force had neither the training nor the vessels required for their colossal task. On March 5 the "Queen Elizabeth" opened indirect fire on the Kilid Bahr forts, shelling them overland from the western side of Gallipoli and apparently putting Hamidieh ii. out of action. Indirect fire was continued the next day on Hamidieh i. and ii. at 21,000 yd. while the "Vengeance," "Albion," "Majestic," "Prince George" and "Suffren" inside the Straits engaged Forts E and F halfway up the Narrows. The weakness in aircraft and trained observers began to show itself when three officers were injured and two seaplanes disabled in two days. On the 7th the "Gaulois," "Charlemagne," "Bouvet" and "Suffren" engaged Fort E (Dardanus) while the "Agamemnon" and "Lord Nelson" (Capt. J. D. McChatock) went up and engaged Medjidieh and Hamidieh i. in the Kilid Bahr group on the north side of the Narrows at 14,000 yd., apparently silencing both. Meanwhile the progress of the minesweepers was poor. The trawlers unable to go more than four knots against the current were an easy target for the guns. On March 10 the minesweepers went up at night supported by the "Amethyst" (Comm. G. J. Todd) and "Canopus" (Capt. H. S. Grant). Two trawlers were hit by 6-in. shell and one sunk by a mine. At home the First Lord was growing impatient and on March 11 sent a telegram to Vice-Adml. Carden urging a decision and suggesting that the forts at the Narrows could be overwhelmed by the fire of the fleet. It was clear that in his case the idea of a gradual reduction of the defences had given place to that of a shock attack. Everything now hinged on clearing the minefields. The trawlers could not face the fire but on the night of the 13th seven of them and five picket boats manned by volunteers made a determined effort, as far as their lack of training would permit, to sweep the channel, supported by the "Amethyst" and "Cornwallis." They steamed up in line ahead on the European side, and at 3:50 A.M. were shooting their sweeps when six powerful searchlights shone out on them. The "Amethyst" opened fire on the searchlights and came under a heavy fire. A 6-in. shell carried away her wheel shafting, and after receiving nine hits she was forced to retire with 22 killed and 38 wounded. The trawlers were driven back under a tornado of fire. This effectually demonstrated the difficulty of sweeping under fire by night and it was decided to attempt it by day under cover of a bombardment. Vice-Adml. Carden's health had broken down and the final attack took place on March 18 under Vice-Adml. John de Robeck. He had with him the "Queen Elizabeth," "Inflexible," "Agamemnon," "Lord Nelson" and 14 older battleships.

It was a clear sunny day when the force mustered for the final attempt. At 10:45 the "Queen Elizabeth," "Inflexible," "Agamemnon" and "Lord Nelson" engaged the Kilid Bahr and Chanak batteries while the "Triumph" and "Prince George" engaged the forts halfway up at Soghandere (F), Dardanus (E) and Kephez. After a bombardment of about an hour and a half the French battleships "Bouvet," "Charlemagne," "Gaulois" and "Suffren" advanced as far as Kephez and engaged the Narrows forts at about 9,000 yards. The forts ceased firing for a time. The "Vengeance," "Irresistible," "Albion," "Ocean," "Swiftsure" (Capt. C. M. Lefroy) and "Majestic," after relieving the six old battleships previously engaged, renewed the attack at 2:36 P.M. while minesweepers continued their operations. Up to this point the day had been going fairly well though the "Inflexible" had been badly hit at 1:15 P.M., her fo'c'sle set on fire and her control station put out of action. Then came the *dénouement* within one short hour. As the "Bouvet" was retiring, she was struck by a mine or shell and in two minutes turned turtle and sank with most of her crew. At 4 P.M. the "Inflexible" struck a mine and was forced to retire. At 4:15 the "Irresistible" struck another; the "Ocean" went to help her and struck another at 6:05 P.M. and both went down, though their crews were saved. All this happened in Arenkoi Bay four or five miles from the entrance on the Asiatic side, where mines had either been laid by a Turkish minelayer on March 8 or may have drifted down from the minesweepers.

The "Suffren" and "Gaulois" were also injured so severely as to require docking. Three ships had been sunk and three disabled, putting one-third of the force out of action before the minefield had been swept. De Robeck had attempted too much. To force a channel defended by a strong minefield and heavy batteries remained to the end of the war a tactical proposition of the first magnitude which was too much for the Germans in the Gulf of Finland and was beyond the compass of the force at De Robeck's disposal. The minesweeping force was an extemporized force of trawlers which attempted to perform a task of exceptional difficulty with no special experience, no special vessels, no special appliances and no special training for the work. The minesweepers and minesweeping talent required for the task had been retained at home. Success at the Dardanelles was sacrificed to the integrity of the Grand Fleet. Lord Fisher would not agree to a renewal of the attempt and there is no reason to believe that a further attempt with

news to Singapore. The big Australian and New Zealand convoy of 38 transports homeward bound, which left Albany on Nov. 1, escorted by the "Minotaur," "Melbourne," "Sydney," and "Ibuki," was approaching Cocos. It was only 55 m. off when the news reached it, and the "Sydney" went off to Cocos I. at full speed. An action ensued between the "Sydney" (Capt. J. C. Glossop, 8 6-in.) and the "Emden" (Capt. von Muller, 10 4·1-in.). By 11:30 the latter was driven ashore, blazing.

With the destruction of von Spee's squadron there remained only, as regards German naval forces at sea, the "Dresden" hiding in the creeks of Tierra del Fuego, and the "Königsberg" shut up in the Rufiji river (German East Africa), both of them powerless for harm. The ocean passages were again secure for Great Britain and her Allies. Samoa and New Guinea had fallen, and a Japanese guard stood at the gates of Tsingtau. In Cameroon, Duala, Buea, and Victoria had been occupied. The naval operations under the conduct of Capt. C. M. Fuller had contributed largely to this success, and the "Cumberland" now joined the stream of British cruisers homeward bound.

*Operations in 1915.*—The year 1915 saw a heavy blow dealt at the German battle-cruisers in the North Sea. An impression prevailed in Germany at this time that the British fleet was preparing to block the Jade and it was decided to send Rear-Adml. Hipper's battle-cruisers as far as the Dogger Bank to reconnoitre on Jan. 24, but the Admiralty had intelligence of this and dispatched Beatty with his battle-cruisers on the 23rd to join hands with Tyrwhitt. They met Hipper's forces on the morning of Jan. 24 and the battle of the Dogger Bank ensued in which the Germans lost the "Blücher" and were driven back to port (*see* 30.848). The battle reacted at once on German naval strategy. Von Pohl, chief of the staff, replaced von Ingenohl in command of the High Sea Fleet with instructions to use extreme caution. The successes of von Weddingen had inclined the German naval staff more and more to submarine warfare which opened with the declaration of a war zone round the British Isles on Feb. 4. Their tendency in this direction was strengthened by the final collapse of their cruiser warfare abroad. News of the "Dresden's" destruction arrived in March 1915. For two months after the battle of the Falklands she had lain hidden in the innermost recesses of the Magellan Straits with half a dozen British cruisers looking for her, and it was not till Feb. that she ventured to creep back into the Pacific in order to meet a German collier south of Juan Fernandez. The "Kent," searching the Barbara Channel (Magellan Straits) with the "Glasgow" at the time, got the news and hastened after her. On March 7 1915 she reached the rendezvous but the "Dresden's" speed enabled her to get away. It was not for long, however. The "Glasgow" had made out the words "Juan Fernandez" in a message the "Dresden" had sent and there, on March 14, the "Kent," "Glasgow" and "Orama" found her and brought her career to an end.

From the lonely islets of the Pacific we must return to Europe for a time. There the centre of interest had shifted from the Grand Fleet to the Dardanelles. After the Dogger Bank action the German fleet became more wary in its excursions and the work of the Grand Fleet was confined to periodical cruises enlivened only by an occasional attack by a submarine. The battle of the Falklands had released a number of older battleships and cruisers but in the North Sea the war was settling down into a state of equilibrium. The Germans rarely came out of the Bight and we could rarely go into it. On sea and land a deadlock had arisen, giving rise to the belief that a better outlet for energy could be found in the Mid East. In this way the idea of the Dardanelles came cranking across the original plans of naval strategy, challenging even the Grand Fleet in its insistency, swallowing at a gulp the Channel Fleet and wrecking Lord Fisher's plans for a Baltic campaign.

The general conception was sound for it was a matter of first-rate importance to gain free access to Russia and the scheme offered strategic political and economic advantages of the first magnitude, but it was begun in a haphazard way and its direction was marred by an inability to distinguish clearly between a naval bombardment and a combined naval and military operation and by a failure to appreciate that two operations unless conducted simultaneously must prejudice one another. The history of the naval side of the subject can only be briefly sketched. Petrograd had asked on Jan. 2 for a diversion to relieve the pressure of the Turks in the Caucasus. The idea of the Dardanelles was broached. Vice-Adml. But here the strategical weakness of the conception would have revealed itself. The forcing of the Straits in itself could do little unless it precipitated a revolution. In default of a revolution the fleet would have been left in the air in the Sea of Marmora, for its ships could hardly pass and repass through a channel a mile wide whose shores were in hostile hands. But the principal objection lay in the fact that any premature bombardment must inevitably wreck or at least imperil the prospects of a combined operation and anticipate surprise where surprise was the essence of success.

But by Feb. 1915 the idea of merging the two operations had crept in. A military force was to be available "to reap the fruits" and was being assembled in Egypt. The opinion found favour that if the navy failed, the army should help—a fatal conception which ignored the real relativity of the two operations. Meanwhile Lord Fisher's attitude of lukewarm acquiescence had changed to one of definite disapproval, but his position was weakened by his adherence to a scheme for landing in the Baltic, much more difficult and dangerous. The War Council definitely approved of the project on Jan. 28, bringing Lord Fisher to the verge of resignation.

The force collected for the purpose consisted of the "Queen Elizabeth" (Capt. George Hope) and "Inflexible" (Capt. R. Phillimore) with a heterogeneous collection of old battleships drawn from the Channel Fleet or which had come home from abroad after von Spee's defeat. In command was Vice-Adml. Sackville Carden who had been admiral superintendent at Malta Dockyard when the war broke out, with Comdr. Roger Keyes as his chief-of-staff. Operations against the outer fort

abrupt close. On July 2 the Russian armoured cruisers "Admiral Makaroff" and "Bayan" (both 2 8-in., 8 6-in.), and the cruisers "Bogatyr" and "Oleg" (both 12 6-in.), all old ships, met the light cruiser "Augsburg" (12 4·1-in.) and minelayer "Albatross" off the coast of Courland and drove the latter ashore at Ostergarn on the E. coast of Gothland (Sweden). The German armoured cruisers "Roon" (4 8·2, 10 6-in.) and the "Lübeck" (10 4·1-in.) proceeded to reinforce them but were chased off by the "Rurik" (4 10-in., 8 8-in.), and when the old armoured cruiser "Prinz Adalbert" (4 8·2-in., 10 6-in.) was hurrying to the spot, she was torpedoed and seriously damaged by E9 (Comm. Max Horton) in the Gulf of Danzig. In Aug. 1915 a strenuous attempt was made by the German Baltic squadron to force the Gulf of Riga, whose possession would have enabled them to take the Russian army in rear, and the 1st and 4th Squadrons were assembled in the Baltic for the purpose, but the Russian minefields offered a serious obstacle and British submarines were again active. On Aug. 19, E1 (Comm. Laurence) torpedoed and seriously injured the German battle-cruiser "Moltke," and she had to return to Kiel at 15 knots. Next day the order came to abandon the operations; all the High Sea Fleet ships were sent back, and there ensued a long period of minor activity in the East Baltic, though British submarines still remained there and did much to disturb the important German iron-ore trade with Sweden during the latter months of 1915.

Meanwhile the Grand Fleet had been carrying out occasional sweeps into the North Sea. The 3rd Cruiser Squadron with the "Nottingham" and "Birmingham" left the Forth on June 18 1915 for a sweep of this sort towards the Skagerack, and crossed the path of a line of four German submarines stationed off the Forth. Five torpedoes were fired at them, but all missed except one on the 20th from U38, which hit the "Roxburgh" and sent her into dock for a time. Some three weeks later came the last echo of the cruiser warfare, when news arrived from the East Indies of the destruction of the "Königsberg" in the Rufiji river on July 11 1915.

After sinking the "Pegasus" off Zanzibar on Sept. 20 1914, she had hidden herself on the E. coast of Africa in the swampy delta of the Rufiji river opposite Mafia I. and the light cruisers "Chatham," "Weymouth" and "Dartmouth" had been sent from the Mediterranean to look for her. The papers of a captured German ship, the "Praesident," gave the first clue to her position, showing that coal had been sent 6 m. up the Rufiji for her use. The "Chatham" (Capt. S. R. Drury-Lowe) arrived off the Rufiji on Oct. 30 and learnt from the natives that a ship was lying up the Suninga branch of the river. The river was blockaded and a blockship sunk in the mouth of the creek. A supply ship, the s.s. "Rubens" (formerly British), had been sent to her from Germany and had made the long journey round Africa in safety, but exact intelligence had been received of her, and the cruiser "Hyacinth" (Rear-Adml. King-Hall) met her off Mansa Bay (near Tanga) and set her on fire. The monitors "Severn," "Humber" and "Mersey" (under Capt. E. J. Fullerton) were sent out later with an aeroplane, and their final attack was made on July 11 1915. Fire was opened by the "Mersey" at 9,500 yd., and hitting was established with the aeroplane's help after the eighth salvo. An explosion was followed by a dense cloud of smoke, and the last German cruiser was left a blazing wreck in the swamp of an African jungle. The ship sunk by the "Hyacinth" in German E. Africa was not the only one which ventured into the North Sea. The "Meteor" slipped over to the Scottish coast in Aug. 1915 and on the night of Aug. 7–8 laid a large minefield of 380 mines off the Moray Firth, sinking the patrol vessel "[illegible]" and taking the survivors of her crew prisoners. In [illegible] came of her movements, and the "Harwich" [illegible] went off at full speed to intercept her, but her captain sunk her and escaped in a Swedish vessel.

In Germany the submarine warfare controversy had reached an acute stage. After the sinking of the "Arabic" on Aug. 19 1916 by U24, orders were issued that no passenger steamers were to be sunk without warning and rescue. The chief of the admiral staff resigned, to be succeeded by Adml. von Holtzendorff. Tirpitz sat at his "lonely table" at Great Headquarters, discontented and furious, and all submarine activities in the Channel and to the westward ceased for a time.

The pressure of the blockade was beginning to be felt (*see* BLOCKADE). It was the British navy's part to intercept all shipping entering the North Sea, in itself an immense task lost to sight in the greater immensity of the war. In the north this work was performed by the 10th Cruiser Squadron, but the New Year of 1916 saw the "Moewe" (Lt.-Comm. Count Nikolas zu Dohna-Schlodien), one of the most notable German raiders, slip through its weather-beaten lines and get safely out to sea, after laying a large minefield on the west side of the Orkneys, where the "King Edward VII." was lost Jan. 5 1916.

*Operations in 1916.*—The year 1916 saw an important change in German naval policy. Adml. von Pohl had been seriously injured in an accident, and his place was taken on Jan. 18 by Adml. Scheer, a strong advocate of an offensive strategy at sea. He received his appointment as commander-in-chief on Jan. 18, and after a conference with the chief of the naval staff, Adml. von Holtzendorff, it was decided to adopt bolder measures.

One of the first fruits of the new policy was the dispatch of the German 2nd, 6th, and 9th Torpedo Flotillas to the Dogger Bank on Feb. 10 1916, where they attacked the 10th Sloop Flotilla belonging to the Humber Patrol and sank the "Arabis." Meanwhile the safe passage of the "Moewe" had induced another raider, the "Greif" (4 5·9-in. and two torpedo tubes), to try and get to sea. The commander-in-chief Grand Fleet had received intelligence of some project of the sort, and his patrols were posted between the Shetland Is. and Norway to intercept her. The "Greif" (with a crew of 306) was sighted by the "Andes" of the 10th Cruiser Squadron on Feb. 29 some 90 m. N.E. of the Shetlands, and the "Alcantara" (Capt. Thos. Wardle) joining in the chase got within 6,000 yd. of her at 0:15 A.M. and ordered her to stop. She was then flying the Norwegian flag and gave the name of the Norwegian s.s. "Rena" from Rio to Trongjhem, but when the "Alcantara" lowered a boat to board, the German ensign fluttered out at the main and she opened fire. A hot action ensued, in which the "Greif" was sunk but the "Alcantara" was hit by a torpedo and went down as well. That same night the "Moewe" managed to slip through the dislocated patrol line and reach home. Directionals had been received that night at 2:53 A.M. of an enemy vessel off Ekersund, but unfortunately, on the assumption that she was coming westward, the patrols had been redisposed to the westward and missed her. Her cruise in mid-Atlantic in the regions of trade winds and flying fish had been a great and successful adventure. She had captured 15 ships of 57,835 tons, of which 14 were sunk. Her most important capture was the "Appano" (Jan. 15, 135 m. east of Madeira), an Elder Dempster liner of 7,781 tons, with the governors of Sierra Leone and Nigeria and a cargo worth £2,000,000 on board. She was sent in to Newport News, where she arrived on Feb. 15, but the German Government's claim was disallowed by the U.S. Supreme Court in March 1917, on the grounds that she arrived without convoy and was sent in with the intention of being laid up indefinitely.

A weightier matter than the return of the "Moewe" was now engaging the attention of Great Headquarters. Scheer when he took over the command had fully expected to see the inauguration of unrestricted submarine warfare in March 1916. Von Tirpitz and von Holtzendorff had appeared at a council of war on March 4 1916 and pressed for a decision, but the Chancellor had again carried the day. Von Tirpitz, unable to bear the constant frustration of his schemes, resigned, and Adml. von Capelle took his place.

The German air raids on England had instigated a counter-attack and on March 24 1916 the Harwich flotillas sailed with the "Cleopatra," "Undaunted," "Penelope" and "Conquest" in support of an aerial operation carried out by the "Vindex" and five aeroplanes against the Zeppelin sheds at Tondern.

The German outpost forces, which had just been reorganized by Scheer, were caught napping, and two outpost trawlers were sunk, but fog and snow interfered with the aerial attack, which was driven off, and only two planes got back. The only naval result was the ramming of G194 by the "Cleopatra" (Tyrwhitt's flagship, Capt. F. P. Loder Symonds) on the way back and the loss of the British destroyer "Medusa" by collision with the "Laverack."

A month later, signs of Scheer's activity were clearly apparent in the resumption of coastal raids. A sortie had already been made into the Hoofden (the narrows between England and Holland) on March 5, but on April 24 a more ambitious operation was attempted. This time the objective was Lowestoft. The whole High Sea Fleet was to take part in conjunction with submarines stationed off the Forth and eight of the newer airships. The actual bombardment was to be carried out by the five battle-cruisers of the 1st Scouting Group, attended by the light cruisers of the 2nd Scouting Group and the 6th and 9th Flotillas. The force put to sea on the 24th, but on its way past Nordeney encountered a nasty setback by the "Seydlitz" striking a mine laid by the "Princess Margaret" in Nov. 1915 and having to put back. Intelligence of these movements had been received, and by 10 P.M. the Grand Fleet had put to sea and was on its way south. During the night the German airships taking part bombed Norwich, Lincoln, Harwich and Ipswich. The German battle-cruisers were seen shortly after 4 A.M. on April 25 by the Harwich forces, consisting of the "Conquest," "Cleopatra," and 16 destroyers, who engaged the "Rostock" and "Elbing," but were driven off by the German battle-cruisers, the "Conquest" being hit by five 12-in. shells and suffering heavy casualties. At 5 A.M. the Germans were off the coast and bombarded Lowestoft and Yarmouth for half an hour. Beatty's battle-cruiser fleet struck down at them towards Terschelling and were off it at 12:30 P.M., but the enemy had passed him and gone home.

The raid had little naval significance, but in order to strengthen the position of the Harwich force in the south, which had been weak ever since the Channel Fleet had been swept off to the Mediterranean, it was decided to station the 3rd Battle Squadron in the Thames ("Hibernia," "Commonwealth," "Zeelandia," "Dominion," "Africa," "Britannia," "Hindustan," all 4 12-in., 9 4·2-in., 10 6-in.) and it sailed for Sheerness on April 29.

The day that saw the bombardment of Lowestoft saw a barrage being laid by the Dover Patrol off the Belgian coast to cope with the German submarines there, which was completed by May 7 (*see* SUBMARINE WARFARE). On May 5 1916 Adml. Jellicoe launched another attack against Tondern sheds. The 1st L.C.S. and 16 destroyers escorted the seaplane carriers "Vindex" and "Engadine" to Horn's Reef. Three submarines were posted there, and the "Abdiel" laid a line of mines (one of which was to catch the "Ostfriesland" on the night of Jutland), while the battle-cruiser fleet waited ready in support with the battle-fleet behind it. Only one seaplane would rise off the water, but the "Galatea" and "Phaeton" damaged a Zeppelin, L7, forcing her to descend near E31, one of the submarines on watch, which completed her destruction and rescued seven survivors.

The attack on the "Sussex" on March 24 1916, with the 80 casualties caused by it, had led to a strong American protest, and as Scheer was on his way across to the Lowestoft raid on April 24 he received a message that submarine warfare was to be carried on in accordance with Prize law (that is, by warning and examination). He at once recalled all the submarines of the High Sea Fleet, and announced that the submarine campaign against commerce had ceased so far as his submarines were concerned. This set free a number of submarines for work in conjunction with the fleet, and Scheer set to work to devise a plan to entice the British fleet out. This was ready by the middle of May. Twenty-two submarines were to be stationed off the British ports, two off Scapa, one off Cromarty, seven off the Forth, one off the Tyne, two off the Humber and one south of the Dogger Bank. The High Sea Fleet was then to appear off the coast of England or Norway in the hope that the Grand Fleet would rush out and be torpedoed by the submarines. Such was the plan of the Jutland operations. The submarines were off their ports by May 23; and U75, after laying mines off the Orkneys on May 29 which were to sink the "Hampshire," proceeded home, the only submarine to achieve any measure of success.

The weather was too bad for air reconnaissance, which was essential for approaching the English coast, so it was decided to try the less risky advance to the Norwegian coast. But the British Admiralty was on the alert, and the Grand Fleet had put to sea on May 30 before the German ships had cleared the Jade. There followed the battle of Jutland (*see* JUTLAND, BATTLE OF). The British lost three battle-cruisers, three cruisers and eight destroyers. The Germans one older battleship, one battle-cruiser, four cruisers and five destroyers. Scheer, threatened with envelopment and destruction, succeeded in making good his escape, and the High Sea Fleet, driven back to harbour, became the buttress of the submarine campaign. It remained intact, a fleet "in being" barring the road to the Baltic and access to Russia with all the consequences which that involved, guarding the Bight and insuring safe entry and exit to its submarines, circumventing British attempts to mine them in and forcing the British Government to keep a mass of craft still locked up in the Grand Fleet when they were wanted for convoy and the tremendous struggle against the submarine.

A single success was achieved by the submarines engaged in the Jutland operation. On June 5, H.M.S. "Hampshire" on her way to Archangel struck one of the mines laid by U75 and went down off the Orkneys, bringing Lord Kitchener's great career to an untimely end. He had arrived at Scapa that day with the weather growing steadily worse, and by the afternoon a gale was blowing from the north-east. Lord Kitchener insisted on sailing, and to give the "Hampshire" a lee it was decided to send her up the west side of the Orkneys instead of the east and she sailed at 5:30 P.M. But the wind had backed to N.N.W., and the destroyers, unable to make head against the gale, had to put back. The "Hampshire" was alone when about 7:50 P.M. she struck one of the mines laid by U75, one and a half miles from shore, between the Brough of Birsay and Marwick Head, and sank in 15 min., losing all but 12 men.

The disposition of submarines adopted for the Jutland operations had met with no success, but in August Scheer devised another and more successful plan, which led to the loss of the "Nottingham" and "Falmouth." This time, the submarines, instead of being stationed off the ports where patrols were constantly on watch, were disposed in lines in the North Sea on the expected track of the British fleet. One line of six submarines was posted off Blyth, another off the Yorkshire coast, and two lines of Flanders submarines off Terschelling. The High Sea Fleet put to sea in the evening of Aug. 18 1916, leaving the 2nd Squadron this time to guard the Bight, and shaped course from Heligoland in the direction of Hartlepool, intending to bombard Sunderland, at sunset the next day, if the British fleet were not encountered.

The battle-cruisers of the 1st Scouting Group were reinforced by the new battleship "Bayern," and by the "Grosser Kurfürst" and "Markgraf," in place of the "Derfflinger" and "Seydlitz," which were still under repair; and to permit of rapid concentration they were stationed only 20 m. ahead of the battle-fleet, with eight Zeppelins, to assist in air reconnaissance. They did not get across unscathed. E23 was waiting for them halfway, and sent two torpedoes into the "Westfalen," forcing her to put back, but Scheer held steadily on. Admiral Jellicoe had ample intelligence of the German movements, and had put to sea at 5 P.M. on Aug. 18. After meeting Beatty's force he was on his way down the East Coast with the battle-cruisers, 30 m. ahead, when the 2nd L.C.S. ran into the first line of German submarines in the latitude of the Farne Is. at 5:55 A.M. on Aug. 19, and though going 20 knots the "Nottingham" was struck by two torpedoes from U52. Admiral Jellicoe immediately turned round and made to the

northward for a time. The "Nottingham" struggling home was hit by a third torpedo at 7 A.M. and sunk. Meanwhile the Harwich forces had sighted the enemy at 6:30 A.M. and proceeded northeast to get in touch with him. But the German forces were too strong for Tyrwhitt's flotillas to attack, and Scheer held steadily across, receiving a succession of reports from his Zeppelins, submarines and the German intercept station at Neuminster, which enabled him to locate exactly the position of the British forces. By 10:30 A.M. Adml. Jellicoe had ample information of Scheer's movements and decided to make for a position off Newcastle to cover the coast. At noon he was some 95 m. east of the Farne Is. steering S.S.E. down the coast, with Beatty's battle-cruisers ahead of him, and the German fleet about 90 m. east of Whitby steering to the westward on a converging course. By 12:30 P.M. Beatty's squadrons were level with Newcastle and only 42 m. from the German fleet, when Scheer turned to the southward, made a push against the Harwich forces and turned home at 2:35 P.M. Adml. Jellicoe, thinking it unwise to follow on account of the danger of submarines, ordered Beatty to turn back at 4 P.M. and directed Comm. Tyrwhitt to proceed to a position off Terschelling to deliver a night attack. At 3:20 P.M. the commander-in-chief received the report of a submarine and ordered Beatty to turn back at once. At 4:52 P.M. while returning, the "Falmouth" of the 3rd L.C.S. was hit by two torpedoes from U66, though going 23 knots at the time. She managed to reach Flamborough Head, where she sank, and U66, though heavily depth-charged by the destroyer "Pelican," got safely away. The Harwich flotillas kept in touch with the enemy fleet till 7:30 P.M., but unsupported by the Grand Fleet dared not press home an attack, and as conditions were unfavourable for a night attack abandoned the pursuit. This was one of the most successful of Scheer's operations, and he intended to repeat it, but in Oct. orders were received to resume the submarine warfare against commerce (under conditions of visit and search), and U boats were no longer available for fleet purposes.

The resumption of the submarine campaign called for a clear passage down Channel, and the 3rd and 9th Torpedo-boat Flotillas were dispatched to Zeebrugge under Comm. Michelsen, the Commodore of Torpedo Flotillas, to raid the Dover Straits barrage. A line of mines and nets had been laid off Zeebrugge in April 1916, and a similar line had been begun across the Straits from South Goodwin towards Snouw Bank and Dunkirk. This was the first serious attempt to attack patrols off Dover, and merits special attention. The barrage in course of construction at Dover consisted of a line of nets fitted with mines, divided into sections marked by light buoys and patrolled by a force of 23 drifters, supported by an armed yacht, an armed trawler, and an old destroyer, the "Flirt." Information of the arrival of the flotillas in Flanders had been received, and the vice-admiral at Dover, expecting an attack either on the Downs or Belgian coast, distributed his destroyer forces to meet it, four in the Downs, eight at Dunkirk and six tribals at Dover. The night of October 26–27 was dark and favourable to the enemy. The Germans attacked in two divisions of five and six boats each. One attacked the centre of the patrol about 10 P.M. and sank three drifters. The "Flirt" had seen them about 9:30 P.M. but took them for the British destroyers from Dunkirk. Hearing the gunfire she thought a submarine was being chased, hurried to the spot, found a blazing drifter, and sent a whaler to save the crew when a heavy fire was opened on her and she sank at once, about 11 P.M. The yacht "Ombra" heard the firing, guessed the cause and gave the alarm, but before the patrols could be withdrawn another division of drifters ran into the enemy and two more were sunk. The destroyers at Dover and Dunkirk were now ordered out, and those in the Downs got under way.

The second section of attackers had proceeded westward, stopped the empty transport "Queen" off Gris Nez and set her on fire. The news of this incident came in at 12:30 A.M. The six destroyers at Dover ("Viking," "Amazon," "Nubian," "Cossack," "Tartar," and "Mohawk") had put to sea at 11:15 P.M., but leaving by different entrances got separated. The "Nubian" sighted destroyers at 12:40 A.M., took them for the Downs division, challenged them and received in reply a heavy fire and a torpedo which blew off her bows and left her blazing. A few minutes later the enemy met the "Amazon" and sent a shell into her boilers. At 12:50 A.M. he met the "Viking" and two destroyers, was challenged, and after giving the usual reply of a broadside disappeared in the night. The Downs division had got to sea at 12:30 A.M. and the Dunkirk division by 11:30 P.M., but neither saw the enemy though the latter heard the gunfire of the "Viking's" action. The Germans got back to Zeebrugge safely, after sinking seven drifters and two destroyers. This was the first of a series of attacks on Dover intended to assist the passage of submarines.

In the north the "Moewe" had got safely to sea again in the winter nights Nov. 23–25, and was followed by another raider, the "Wolfe" (Capt. Karl Nerger), on Nov. 30.

Submarines were again at work, and on Nov. 5 U30 and U20 (which had sunk the "Lusitania") ran ashore off Bovsbjerg (Denmark) in a fog, and Scheer sent a half flotilla of destroyers supported by the "Moltke" and the 3rd Squadron to get them off. J1 (Comm. Lawrence) got there too, and torpedoed the battleships "Grosser Kurfürst" and "Kronprinz," driving them both back into harbour. The Kaiser remonstrated with Scheer for risking two valuable battleships in this work, but Scheer maintained that sooner or later German naval strategy must resolve itself into a *guerre de course*, leaving only one task for the fleet to perform—to get submarines safely out and safely home again.

Unrestricted warfare (that is, sinking at sight without warning) was now being urged by the general staffs of both navy and army in Germany, but at a council of war held on Oct. 16 it was decided to postpone it till a last effort had been made to negotiate for peace. On Dec. 12, after the capture of Bucharest, a note went out to the Allied Powers inviting them to enter into negotiations to avoid further bloodshed. It was the first symptom of Germany's defeat, but it was based on the conception of her indestructible strength and was rejected by the Allies. The peril of the submarine was growing more and more acute, and on Nov. 29 1916 Adml. Sir John Jellicoe was summoned to the Admiralty to take the post of First Sea Lord, and his command passed to Adml. Sir David Beatty.

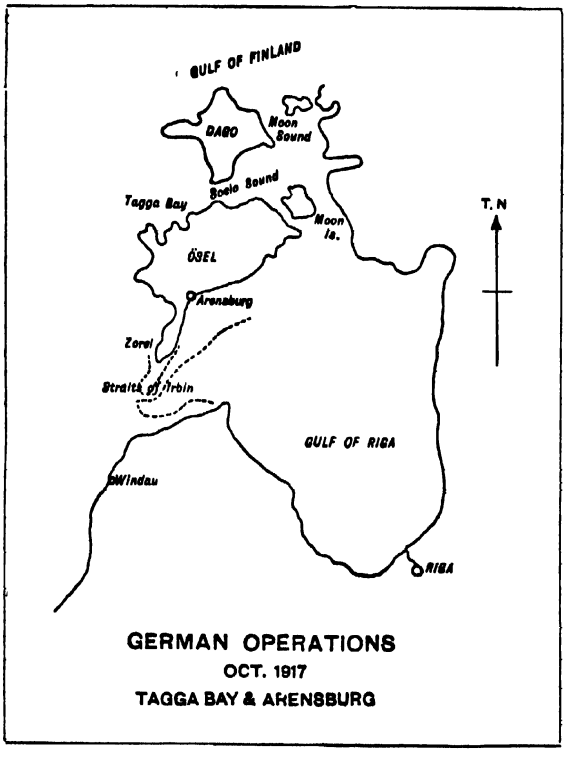
*Operations in 1917.*—The new year of 1917 saw the controversy which had so long raged in Germany decided in favour of the submarine. In her growing need she was forced to have recourse to unrestricted warfare, and on Jan. 9 an Imperial Order went out to commence it on Feb. 1. The war at sea had now to adjust itself to the new conditions; but though the High Sea Fleet had only to ensure a safe entry and exit to its submarines, it continued indirectly to exercise a potent influence on the campaign, for as a "fleet in being" it compelled the Grand Fleet to remain concentrated and ready for action, and prevented its units and flotillas being dispersed to escort convoys and hunt the submarine.

The activity of the destroyer flotillas did not diminish. In the Hoofden, a short sharp destroyer action took place in the early morning of Jan. 23, when a Harwich force of three light cruisers and some 14 destroyers met the German 6th Flotilla of eight destroyers on its way from Zeebrugge to the Bight. It was a cold dark night and a general mêlée at short range ensued, which developed into two encounters. In the first, V69, the flotilla leader's boat, was badly hit and driven into Ymuiden, and S50 had to put back. In the second, which took place off Schouwen Bank, a British destroyer, the "Simoon," was hit in the bow by a torpedo and sunk. Feb. 1 saw the beginning of the momentous campaign followed by the rupture of diplomatic relations between Germany and the United States. The operations of the German fleet were now directed towards supporting their submarines, and with this in view a succession of raids was made on Dover Straits.

The first took place on the night of Feb. 25 and accomplished nothing. The barrage patrol at the time consisted of five L-class boats, patrolling on courses S.W. and N.E. about 4 m.

apart. The German destroyers appeared, and after opening fire on the "Laverock" retired. March 17 1917 saw a more successful attempt. This time the barrage patrol consisted of four destroyers, the "Laertes," "Laforey," "Llewellyn" and "Paragon," patrolling on separate beats running S.W. and N.E. about 2 m. apart. Off Deal were lying the "Canterbury," "Faulknor" and four destroyers; the "Broke" and five destroyers were in Dover. At 11:50 P.M. the "Paragon," on patrol at about the centre of the barrage on a N.E. course, sighted three or four destroyers, challenged them, received a heavy broadside and a torpedo, broke in two and sank. The "Laforey," 2 m. off, under the impression that the "Paragon" had struck a mine, was on her way with the "Llewellyn" to pick up survivors when the latter was hit by a torpedo, which was attributed at the time to a submarine. The destroyers at Dover went out but saw nothing, though the Germans were seen at 2:35 A.M. off Broadstairs, where they sunk a merchant ship and disappeared. The "Moewe" had slipped out to the north again, and while these events were happening in the Straits got back to Kiel after capturing 27 ships, one of which she had succeeded in sending in to Swinemunde. But another raider on the way out had not been so fortunate. At 4 P.M. on March 17 the a.c. "Achilles" (Capt. F. M. Leake) and the a.m.s. "Dundee" (Comm. S. M. Day, R.N.R.) had intercepted the "Leopard" disguised as the Norwegian s.s. "Reina Norge," 200 m. N.E. of the Faroes, and after a short action had sent her to the bottom.

April 20 saw another raid at Dover, but this time the raiders did not escape so easily. The system of patrols had been changed since the last attack. Instead of patrols of single destroyers, two patrols were maintained, one called the Western Barrage Patrol of two flotilla leaders patrolling on the N. and W. side of the Straits as far as the S. Goodwin Light vessel. The other, called the E. Barrage Patrol, consisted of a division of destroyers, patrolling on a line S.W. from a buoy approximately halfway between Dover and Calais. Reserves were available at Dover and Deal as before, and on the night in question the W. Barrage Patrol consisted of the "Broke" (Comm. E. R. G. Evans) and the "Swift" (Comm. A. Peck). The German force, consisting of the 2nd Flotilla, which comprised their best and fastest boats, was in two sections. One went off to the S. and appeared off the French coast. The other of about six boats hugged the northern shore and fired at the English coast off Dover in an aimless sort of way. The night was dark, and at 12:45 A.M. they were on their way home about 3 m. E. of the S. Goodwin on an easterly course when they were sighted on the port bow about 600 yd. off by the "Swift" and "Broke," steering an opposite course. This time there was no challenging. The "Swift" fired a torpedo, put her helm hard-a-starboard and attempted to ram, but passed through the enemy's line and went off in pursuit of the leader. The "Broke" fired a torpedo, turned hard to port and crashed into G42, the third boat in line. A hand-to-hand fight ensued in the darkness with German boarders, who were driven back by the fo'c'sle gun's crew led by Midshipman Donald Gyles. The "Broke's" engines were disabled by a shell, but she shook herself clear and completed the destruction of another destroyer, G85, already disabled by one or both of the torpedoes previously fired. The reserve division which had put to sea from Dover, only arrived in time to help to pick up the German survivors. This ended the raid of April 20, which made the "Broke" and Comm. Evans famous, and with the exception of two ineffectual sorties on April 25 and May 2, when the Germans shelled Dunkirk and Ramsgate, stopped such ventures for nearly a year.



On April 6 the United States entered the war, and Vice-Adml. W. S. Sims was dispatched to determine the best methods of coöperating with the Allies. This was a black month for merchant shipping. At sea the war developed into a protracted struggle with the submarine, which became by degrees the dominant aspect of the war (*see* SUBMARINE WARFARE), while the battle-fleets were active as breakwaters behind which the submarine and its antagonists fought out the issues of the war at sea. The reply to the submarine took three forms, the reorganization of the naval staff, the institution of a convoy system (*see* CONVOY), and the development of antidotes in the form of mine barrages and technical devices such as hydrophones and depth charges. In these spheres the United States navy was able to render valuable assistance: convoys required for destroyers, which the Grand Fleet could not supply. The U.S. destroyers, the first six of which under Comm. J. K. Taussig arrived at Queenstown on May 4, eased the situation and proved a welcome and necessary reinforcement.

In the Mediterranean the war had become more and more a war of flotillas. There the Straits of Otranto took the place of the Straits of Dover and a force of some 50 vessels, chiefly drifters, patrolled it to prevent the passage of German and Austrian submarines from their base at Cattaro. These little ships were attacked by a force of Austrian cruisers and destroyers on May 15, and as they stoutly refused to surrender, 14 were sunk, the skipper of the "Gowan Lea" receiving a V.C. for his gallant efforts to engage an overwhelmingly superior force. In the "Floandi" the wireless operator, Harris, was hit, but continued to send out messages till he fell dead at his post. The light cruisers "Dartmouth" and "Bristol" heard the call, and on their approach the enemy fled back to Cattaro; though the "Dartmouth" (Capt. A. P. Addison) was hit by a torpedo but got safely back.

At Dover Adml. Sir Reginald Bacon had endeavoured to extend the war against the submarine to the land and to attack it in its base by bombarding the locks at Zeebrugge and Ostend. These bombardments were carried out in summer by the monitors "Lord Clive," "General Wolfe," "Prince Rupert," "Prince Eugene" (all 2 12-in.), "Marshal Soult," "Erebus" and "Terror" (all 2 15-in.). The two latter joined the force in 1917 and took part with the "Marshal Soult" in an important bombardment off Zeebrugge on May 12 1917, carried out at a range of 28,000 yards. Though these bombardments did not actually prevent the Germans using the ports, they damaged the dockyards and made it more difficult for them to do so, besides adding largely to British experience of bombardment work. During a shelling of Ostend on June 5 six German destroyers sallied out but were engaged by the Harwich Flotilla and driven back to port with the loss of S20. It was only now that the British authorities woke up to the extent to which the enemy continued to ply his trade along the coast between Rotterdam and German ports. The Harwich Flotilla began to harass it and succeeded in sinking some 24 ships during the year, capturing four on July 16 and driving two others ashore. The traffic between Sweden and Germany could no longer be checked, for with the collapse of Russia the Baltic had passed completely under German control. On July 9 the British battle-fleet received a severe blow in the loss of one of its dreadnoughts, the "Vanguard" (Capt. Jas. D. Dick), by an internal explosion, in the same terribly sudden way as the "Bulwark" and "Natal." She was lying at anchor in Scapa when at 11:20 P.M. a great sheet of flame leapt up from her forward, and when the smoke cleared away she was gone. Seven Allied ships-of-war suffered this fate during the war—the "Bulwark" at Sheerness Nov. 26 1914, "Benedetto Brin" Sept. 27 1915, "Natal" at Invergordon Dec. 30 1915, "Leonardo da Vinci" Aug. 2 1916, "Tsukuba" Jan. 14 1917, and "Kawachi" July 12 1918.

Meanwhile a big project for mining Heligoland Bight had been given to the Plans Division as its first task, and preparations for it were steadily progressing, though its execution was delayed till Oct. by lack of mines. The enemy's outpost forces and minesweepers were not left immune from attack, and on Sept. 1, the 4th L.C.S. and 15th Flotilla made a raid on the Channel by Horn's Reef, driving four German minesweepers ashore off Ringkiobing. These minesweepers, working sometimes 150 and later 180 m. from Heligoland, formed an excellent target for attack, but as they always had heavy ships waiting in support and British heavy craft could not risk mined waters, British light-cruiser raids could not be carried out.

No big operation had taken place in the Baltic since 1915, and a German incursion into the Gulf of Finland, in Nov. 1916,

**GERMAN OPERATIONS**
**OCT. 1917**
**TAGGA BAY & ARENSBURG**

had resulted only in the loss of seven destroyers by mines and the abandonment of the enterprise. But in Sept. 1917 the capture of Riga by the German army (Sept. 3) opened the way for a combined operation, which was to prove the death-blow of Russia, then in the throes of revolution. The German navy's task was to transport an infantry division to the island of Osel and effect a landing there, with the object of capturing the island and its batteries, and opening the Straits of Irbin so as to give direct access by sea to the Gulf of Riga. Transport was prepared for 23,000 men and 5,000 horses, and it was decided to land at Tagga Bay on the northward side of the island. The naval force detached for the purpose under Vice-Adml. Ehrhardt Schmidt consisted of the battle-cruiser "Moltke" (flag.), the 3rd and 4th Squadrons comprising ten of the latest battleships, and the 2nd Scouting Group, which with the Baltic light cruisers mustered eight light cruisers in all. A strong force of destroyers went with them, including the 2nd, 8th, and 9th Flotillas and the 7th, 13th and 12th Half Flotillas, numbering altogether 47 boats under Comm. Heinecke.

Nineteen transports were requisitioned for the purpose, with a tonnage of 153,664 tons. Preparations for the enterprise were begun on Sept. 12; on Oct. 9 the troops embarked and on Oct. 11 the fleet put to sea from Libau. Osel is an island of moderate size about 30 m. across at the entrance to the Gulf of Riga, with the Straits of Irbin running between it and the mainland. On the night of Oct. 11 the fleet was approaching Tagga Bay, with the minesweepers steaming slowly in front. But time was precious and rather than risk losing the chance of surprise at daylight Adml. Schmidt ordered the minesweepers out of the way and went straight in with his fleet. He reached Tagga Bay safely, and though the battleships "Bayern" and "Grosser Kurfürst" struck mines in taking up their positions for bombarding the batteries in the Sound of Soelo between Dago and Osel, they were able to perform their task. The advanced troops got safely ashore in motor-launches and three small steamers at 5:30 A.M., and the transports entered the Bay at 6:30 A.M.

The German fleet's next task was to penetrate into Moon Sound. The 2nd Flotilla and 12th and 13th Half Flotillas had pushed through Soelo Sound, and covered by the fire of the "Kaiser" and "Emden" had driven their enemy back with a loss of only one boat sunk by a mine, and three damaged. But the tables were turned by the appearance of the Russian battleship "Slava" which put up an obstinate fight and drove them back in turn, a good instance of the power of heavy guns working behind a minefield. The Russian small craft were still sheltered by their battleships in Moon Sound, which now had to be approached by the S. of Osel through Irbin Straits. This channel was commanded by the batteries at Zorel on the S. point of Osel, but these were bombarded and silenced on Oct. 14 by four battleships and blown up by the Russians. A chart of the minefields had been captured ashore, and with its help the Straits of Irbin were swept. By the morning of Oct. 16 the fleet was inside the Straits before Arensburg, and facing the southern entrance to Moon Sound that evening. The Russian battleships "Slava" and "Grozdani" engaged the Germans and an action ensued, in which the "Slava" was sunk and the Russians driven off to the northward. By Oct. 17 the German force was in complete occupation of Osel, and Arensburg was being organized as a base for the fleet. Dago I. was now captured, and Vice-Adml. Schmidt proposed to push on through a big minefield in the N. of Moon Sound into the Gulf of Finland.

The operation was analogous in some degree to that of the Dardanelles and British raids on the Bight, namely the attack of a large intact minefield protected by heavy guns or supported by a fleet in being. British submarines were beginning to show themselves, and the "König Albert," the "König" and "Kronprinz," had all been attacked. The detachment of so large a force had naturally given rise to some anxiety on the part of the German commander-in-chief in the North Sea, which had not been diminished by the mining of the "Bayern" and "Grosser Kurfürst." It was decided to recall the 3rd and 4th Squadrons and the 1st Squadron was sent to relieve them, but on Oct. 29, when the "Markgraf" struck a mine in Irbin Straits, an order was dispatched to bring the operations to an end, and the naval part of the campaign came to an abrupt conclusion.

This campaign offered a welcome opportunity of giving the fleet some active employment, for symptoms of the spirit which was to end in Germany's collapse were already beginning to appear. Sporadic outbreaks of mutiny had occurred in the 3rd Squadron as early as May 1917, and in Aug. the men in the "Prinz Regent Luitpold" refused to put to sea and were isolated with their ship in Schillig Roads. A mutiny broke out in the "Kaiserin" on the ostensible grounds of insufficient food and the "Kaiserin," "Kaiser," and "König Albert" were sent to Brunsbüttel for recreation and leave. The crew of the "Westfalen" were reported to have killed their captain, and a light cruiser was said to have made for Norway and been turned back by a torpedo-boat flotilla. Certain it is that the spirit and courage of the German fleet were beginning to flag, though it was still far from collapse, as British convoys had good cause to know before the year was out. The convoy system, as one of the most effectual replies to the German policy of submarine warfare, was a natural target of attack, and on Oct. 17 the Scandinavian convoy received a severe blow. This convoy sailed regularly from Lerwick to the Norwegian coast and back, and on this occasion was on its way to Lerwick, consisting of 12 ships (two British, one Danish, five Norwegian, three Swedish), under the escort of only two destroyers, the "Strongbow" (Lt.-Comm. Ed. Brooke) and "Mary Rose" (Lt.-Comm. Chas. L. Fox). It was about halfway across, going about eight knots, at dawn about 6 A.M. on Oct. 17, when two cruisers were seen two points before the port beam coming up at about 25 knots. These were the "Brummer" and "Bremse," two fast German light cruisers completed in 1916 and armed with four 5.9-in. The "Strongbow" challenged thrice, and the enemy opened fire at 6:15 A.M., overwhelming her with the first salvo. A shell entered the engine-room, cutting the main steam-pipe and brought the ship to a stop; the bridge was wrecked, the captain badly wounded. The "Mary Rose" was also sunk after a short fight. Neither of them had time to make a wireless

signal, and the light-cruiser squadrons cruising to southward of the route knew nothing of the action, a clear instance of the necessity of an escort being within range of a convoy and not out of sight. The enemy went off at 8:20 A.M. after sinking nine of the merchant ships. The armed trawler "Elise" stood gallantly by the "Strongbow," and saved most of the survivors. The losses of the "Mary Rose" and "Strongbow" were 86 and 46, and as the armed trawlers "Elise" and "P. Fannon" had no wireless, it was not till 7 P.M., when they arrived at Lerwick, that any report of the action was received. This led to a general revision of the arrangements for convoy in the North Sea, but was also closely related to the general strategy of the war. There was a distinct disinclination both at the Admiralty and at sea to use the Grand Fleet to cover the convoys. But this was clearly their business. War is an endeavour to bring such pressure to bear on an enemy as to force him to submit to your will. In 1917 a grinding pressure was being brought to bear on Germany by the blockade. The enemy replied with a vigorous and effective attack on British maritime trade, not with surface craft, for these were held in check by the Grand Fleet, but with submarines. The British replied with convoy, and the German riposte was sudden and swift cruiser raids. The British answer to this was not to abolish convoys but to escort them in such strength as to force the Germans to bring their whole fleet out to attack, as actually happened in April 1918. This was the normal way of bringing about a battle at sea, but the use of wireless directionals had induced what may be called a policy of immediacy, in which the main fleet had to be held ready for immediate excursion and attack, and was jealous of any other use of its craft. But the opportunity of a great and decisive battle had been lost. The German operations in the Baltic in the autumn of 1917 clearly showed that they were not prepared to risk another fleet action in the North Sea, and in these circumstances the escort of convoys became one of the most important functions of the British fleet.

November was marked by light-cruiser raids both in the Cattegat and Bight. The Cattegat, a sort of "No Man's Sea" at the beginning of the war, had become more and more a sphere of German activity. The German-Swedish convention assuring free passage through the Sound had been denounced; minefields and guardships guarded the southern end of the Sound; ships proceeding to hostile ports were refused passage, and decoy ships cruised in the Cattegat to take the offensive against British submarines. One of these was the "Kronprinz Wilhelm" under command of Capt. Lauterbach, which was cruising off Kullen Light on Nov. 2 at 7 A.M. when several British destroyers swept down on her and opened a devastating fire. Her stern was blown off by the explosion of the after magazine, and in a few minutes she was burning fiercely fore and aft. This incident, small enough in itself, had a considerable effect in checking German activity in the Cattegat, and seems to have led them once again to confine their cruises to the Baltic and the Bight. In the Bight the British minelaying, which started in earnest in the last quarter of 1917, called for an immense expansion in the organization of German outpost and minesweeping forces, and necessitated constant trips by groups of minesweepers and barrier breakers (ships specially constructed with bows filled with concrete) along the swept channels. As the area of the minefields grew, the channels grew longer and longer, and the minesweepers became more and more exposed to attack, and had to be supported by light cruisers and battleships. These were the circumstances leading to an engagement on Nov. 17 1917 which affords an interesting illustration of the important part played by German battleships and battle-cruisers in keeping the Bight open for submarines.

Three German minesweeping half flotillas were making a test trip that morning, escorted by the 14th Half T.B. Flotilla and covered by the light cruisers of the 2nd and 4th Scouting Groups, supported by the "Kaiser" and "Kaiserin" lying off Heligoland. The group was on the point of starting when they were attacked at 7 A.M. by a force consisting of the "Courageous" (R.A. T. D. W. Napier) and "Glorious" (now forming the 1st C.S.), two battle-cruisers, the "Renown" and "Repulse," several light cruisers including the 1st and 6th L.C.S. with the "Caledon" and "Calypso," and a number of destroyers. The two former ships had been built by Lord Fisher for use in the Baltic, and were of special design, 786 ft. long over all, 22½ ft. draught, 30 knots seagoing speed, with four 15-in. guns and a 3-in. belt. The horizon was misty and an action developed with the German light cruisers at about 12,000 yd. running to the south-east. The fight began to approach the minesweepers, which had made off at full speed to the S.E., while the "Nürnberg," "Pillau" and the German destroyers tried to screen them with a smoke cloud. At 8:50 A.M. a destroyer attack was made by the British on the 2nd Scouting Group without success and a counter-attack was made by the enemy in which the "Königsberg" and "Frankfurt" fired torpedoes without hitting. The former was hit by a heavy shell, which went through all three funnels, and landing in a coal-bunker started a fire. At 9:30 the "Kaiserin" and "Kaiser" came in sight, and Rear-Adml. von Reuter tried to draw the British down to them. The "Kaiserin" got within range and scored a hit, but on the arrival of the battleships the British withdrew before the "Moltke" and "Hindenburg," which were coming up, could reach the scene. Several hits were scored on both sides, and on the German side 21 were killed and 10 severely wounded, but only one outpost vessel was lost. On the British side the "Calypso" was hit and her captain (Capt. H. L. Edwards) killed. The coöperation of the German battleships in supporting their minesweepers, and the difficulty of joining battle on the edge of a minefield, were the principal features.

British attack on the German minesweepers was answered by another German thrust at the Scandinavian convoys made by the German 2nd Flotilla on Dec. 12. The 3rd Half Flotilla proceeded to the Tyne, and after going up the coast and attacking two or three steamers returned about 6 A.M. The 4th Half Flotilla under Lt.-Comm. Hans Holbe proceeded to the northward, and at 7 A.M. on Dec. 12 was in sight of Udsire on the Norwegian coast. Proceeding to the northward he sighted at 11:30 P.M. a British convoy of six steamers escorted by two destroyers and four trawlers, approaching Norway on an easterly course and about 35 m. from the coast. The destroyers were the "Pellew" and "Partridge," who left the convoy and engaged the German destroyers at about 5,000 yards. The four armed trawlers with the convoy were sunk. The "Partridge" received a shot in her main steam-pipe, which brought her to a stop. She fired her torpedoes, but one stuck in the tube and another which hit V100 did not explode. The "Pellew," pursued by three destroyers, managed to escape in a squall of rain. All was over in three-quarters of an hour, and the flotilla returned to Kiel with four officers, 48 men and 23 of the merchant crews as prisoners. Two armoured cruisers, the "Shannon" and "Minotaur," were at sea as a covering force, and receiving a signal from the "Partridge" for assistance steamed at full speed to the spot. But again it was too late. The 3rd L.C.S. was also at sea and actually 85 m. to the S.E., but it also failed to intercept the enemy—another illustration of the weakness of covering forces being out of sight of the forces they are intended to cover. The fact is that Grand Fleet cruiser forces were disinclined to be merely escorts. They preferred to be "covering" forces some way off, and the enemy eluded them. The raid led to the provision of stronger covering forces and to considerable changes in the Scandinavian convoy system, which had almost broken down under these successive blows.

The Dutch convoy in the S. suffered a little later an equally severe blow of a different kind. It was one of the principal duties of the Harwich Flotilla to escort the Dutch convoys, and on Dec. 23 at 3 A.M. four of its destroyers were steaming to the southward at 15 knots a few miles N. of the Maas Light buoy when they stumbled into a German minefield in that vicinity. The "Torrent," "Surprise," and "Valkyrie" all struck mines in rapid succession and sank before they could reach the shore.

The year was now drawing to a close, but before it closed Adml. Sir John Jellicoe had left the Admiralty, and his place

as First Sea Lord was taken by Adml. Sir Rosslyn Wemyss. Adml. Jellicoe's departure was associated with that of Vice-Adml. Sir Reginald Bacon's from Dover about the same time. The Belgian coast had acted as a fatal magnet to the Dover Command. All through the summer of 1917 Dover had been absorbed in preparations for what was known there as the Great Landing, a project for landing a division on the flank of the German army in conjunction with a general advance. Enormous pontoons of a special design, each to be pushed by two monitors, had been devised by Adml. Bacon, who had devoted an immensity of labour and attention to the scheme. But events had taken a different turn. The army did not want divisions landed in Belgium. The Admiralty wanted Dover Straits closed to submarines, and when difficulties arose as to the execution of their plans, it was considered necessary to send the Director of Plans, Rear-Adml. Sir Roger Keyes, to Dover to close the Straits. This he did, and very effectually. The war at sea was gradually expressing itself more and more in terms of submarine warfare. Nothing else mattered. The Dover pontoons were ingenious, but they did not close the Straits. History was merely repeating itself. Sir Sidney Smith in earlier days had made the same mistake. He spent much of his time preparing plans and devising pontoons for a landing on the Flemish coast, till Lord Keith complained to the Admiralty that one-third of his force was employed in this way to the detriment of trade in the Channel, which was suffering from privateers.

*Operations in 1918.*—All this time the Black Sea had been the scene of a sporadic warfare between the Russian and Turco-German forces. Russia had a considerable force in these waters. She possessed at the outbreak of war two good pre-dreadnoughts, the "Ievstafi" and "Ivan Zlatoust" (1906, 4 12-in., 4 8-in., 12 6-in.), to pit against the "Goeben," and three dreadnoughts, the "Ekaterina II.," "Imperatriza Maria" and "Alexander II." (all 10 12-in., 20 5-in.), which were on the stocks at Nikolaieff. Her inability to face the "Goeben" with pre-dreadnoughts, and her military commitments, prevented her coöperating on a large scale against Turkey during the Gallipoli campaign, but by the end of 1915, after the completion of the three dreadnoughts, the control of the Black Sea passed into her hands and ensured her communication with the Caucasus. The collapse of Russia in 1917 and the mutiny of the Black Sea fleet led the "Goeben" to look to the westward, and on Jan. 20 she and the "Breslau" made a sortie from the Dardanelles directed against any Allied craft that might be cruising in its vicinity. The British force in the area consisted of the British Aegean Squadron under Rear-Adml. Hayes Sadler, a somewhat heterogeneous collection comprising the "Lord Nelson" (flag.) and "Agamemnon," 6 old light cruisers, 12 monitors, 7 sloops and 27 old destroyers. The only ships which could have opposed the "Goeben" (8 11-in.) were the "Lord Nelson" and "Agamemnon" (each 4 12-in., 4 9·2-in.); the former was at Salonika, where the rear-admiral had gone to confer with the British general and French admiral, and the latter (Capt. P. W. Dumas) was lying at Mudros in the island of Lemnos. The ships in the immediate vicinity were the destroyers "Tigress" (Lt. J. B. Newill) and "Lizard" (Lt. N. A. Ohlenschlager) of the 5th Flotilla, patrolling off the Straits, and the monitors "Raglan" (Comm. Visct. Broome) and M28 (Lt.-Comm. Donald Macgregor) anchored in Kusu Bay at the N.E. corner of Imbros some 15 m. from the Straits. The "Goeben" (Vice-Adml. von Rebeur Paschwik) and "Breslau," or to give them their Turkish names, the "Sultan Selim" and "Medilli," sallied out about 5 A.M. unobserved by the lookout station on Navro I. and steered for Imbros, shadowed by the "Tigress" and "Lizard." The "Raglan" sighted them at 5:35 and gave the alarm by wireless. She was engaged by the "Breslau" and set on fire, and after a few shots from the "Goeben" sank. The "Breslau" then opened fire on M28, which burst into flames and blew up with her captain at 6:27 A.M. The "Goeben" and "Breslau" went off to the southward, but about 3 m. off the S.E. point of Imbros the "Breslau" entered a minefield, and was sunk by mines at 7:07 A.M., 40 survivors being picked up by the "Tigress." The "Goeben" seems to have struck a mine about the same time, and after continuing south for some miles headed for the Dardanelles, followed by aircraft, and beached herself on the shoal off Magara. The "Raglan's" signal set the whole squadron in motion, and even the old cruiser "Europa" started to raise steam. The "Agamemnon" put to sea, and was on her way towards the Straits cleared for action when news arrived that the "Goeben" was returning to the Dardanelles. Almost simultaneously came a signal from the "Lord Nelson" ordering her to rendezvous off Cape Paliuri on the coast of Macedonia.

A series of air attacks were made on the stranded "Goeben," and in the course of the ensuing week more than 15 tons of bombs were dropped round her with several hits, but the 112-lb. bombs failed to inflict any vital damage. An heroic attempt was made to torpedo her by E14 (Lt.-Comm. Geoffrey White), but the defences of the Straits were too strong, and the E14 was sunk and her captain killed. The separation of the "Lord Nelson" and "Agamemnon" had been criticised, but even if we suppose that one had been on patrol outside the Straits and the other at Lemnos, the "Goeben" was more than a match for one and the sortie was made too quickly for the other to arrive in time. The "Goeben" was still too formidable an antagonist for a single ship of the "Lord Nelson" class, and in these circumstances the minefield provided the best solution of the problem, though in view of the overwhelming superiority of the Allied forces in the Mediterranean the episode does not reflect very great credit on the strategy of the Allied arms.

In the North Sea the increased activity in the Dover barrage led inevitably to another German raid. The barrage of deep mines which had been laid across the Straits was now patrolled at night by a strong force of drifters, and illuminated by brilliant flares and searchlights in trawlers and destroyers, in order to discover enemy submarines and force them to dive. The Germans sallied out against it on Feb. 15. The disposition that night was as follows: In the Downs—"Attentive" and three destroyers; West Barrage Patrol off S. Goodwins—"Swift" and "Marksman"; East Barrage Patrol (south and east side of Straits)—"Termagant," "Zubian," "Melpomene" and "Amazon." On the line Folkestone to Gris Nez there were stationed 58 drifters, supported by Monitor 26 off the N.E. Varne buoy and the old destroyer "Syren." All the conditions were favourable for a German raid; a moon three days old set at 11 P.M., and the east-going stream to assist the raiders home began to run at midnight. The light of the barrage could be seen a long way off. The flares and searchlights had a dazzling effect and the whole area was full of glare, varying in intensity as flares burnt up and died down and searchlights flickered and hovered. In such surroundings the flash of gunfire might be overlooked or might easily be mistaken for an attack on a submarine. If enemy destroyers were seen the general alarm for a surface craft raid was to be given; this was a green firework of any description, and on this signal all drifters had to evacuate the minefield and close the nearest land. The German 2nd Flotilla (B98, V100, G101, G102, G103, G104, B97, B109, 110, 111, 112) had again been chosen for attack and came straight from the Bight. At 11:30 P.M. on Feb. 15 it was off Sandettié Bank close to the Straits, where it split into two halves, one going towards Folkestone, the other towards Gris Nez. The northern force was sighted by the trawler "Sabreur" about 12:40 A.M. off Folkestone. She took them for British destroyers hunting a submarine, and made no sign. The minesweeper "Newbury" was burning a searchlight close by, and as the destroyers passed they opened a heavy fire and left her a blazing wreck. They then made off to the S.E. down the drifter line, sank two drifters, damaged a minesweeper and motor-launch, and disappeared to the N.E. about 1:15 P.M. It would appear impossible for all this to happen without an alarm, but no alarm went up. The motor-launch thought she had got mixed up in an attack by British destroyers on a submarine. No news was received at Dover, and the Western Barrage Patrol saw only a few faint flashes about 1 A.M. Meanwhile the German southern detachment had reached the southern end of the

barrage about 12:55 A.M. There they opened fire on the trawler "James Pond," a searchlight vessel, and set her on fire; then proceeding slowly to the N.W. along the drifter line they sank the drifters "Cloverbank," "Cosmos" and "Jennie Murray." One of these seems to have sent up a green light, which led to a general retirement towards Dover, but two more drifters, the "Christina Craig" and "Silver Queen," were met and sunk by the enemy as he retired to the east. Meanwhile the monitor M26 and the destroyer "Syren" remained serenely at their posts under the impression that the firing was associated with an air raid. M26 saw a green light to the southward about 1 A.M., and without repeating the signal ran down there at full speed (9½ knots), and must have passed fairly close to the enemy, but finding everything quiet returned to the N.E. Varne about 2:10 A.M. By this time the firing had been heard at Dover and the rear-admiral asked for its reason at 1:28, but it was not till 2:52 that he heard that M26 saw a green light.

One more glimpse was caught of the enemy. About 2:20 the "Termagant," with the Eastern Barrage Patrol, was in about the middle of the Straits on a S.W. course, when the "Amazon" (2 4-in.), the last ship in the line, caught sight of three destroyers stealing past about 400 yd. off. She thought they were on their way to Dunkirk, and though they failed to reply to her challenge reported them as British. The senior officer (Comm. M. R. Bernard) was not satisfied, and asked if they had replied to the challenge, but by the time the question and answer got along the line the enemy were out of sight. By 2:30 evidence of a raid was taking shape. Reports of burning drifters and survivors were coming in, but it was not till 3:18 that the "Termagant's" report of passing three destroyers came in and banished all doubts. The losses inflicted by the enemy were seven drifters and one trawler sunk and three drifters and one minesweeper damaged. Had the alarm gone and been repeated immediately the enemy was seen the losses would have been less and the enemy might have suffered more.

They were not so fortunate, however, a month or so later. On March 21 the destroyers "Botha" (Comm. Roger Rede, 2 4.7-in., 2 4-in.) and "Morris" (Lt.-Comm. P. R. Percival, 3 4-in.) were lying in Dunkirk, with three French destroyers close by, when a burst of firing was heard off shore at 3:30 A.M. The British slipped, and passing through the Zuidcoote Pass, a narrow channel between the Dunkirk and Ostend roads, came upon the German destroyers retiring. The exploit of the "Broke" was repeated. The "Botha" rammed a German at full speed and cut it in half. Another was disabled by the fire of the two boats. A torpedo then hit the "Botha" in a coal-bunker and brought her to a full stop, while the enemy disappeared towards Ostend with the "Morris" in chase. She returned after seeing them enter Ostend Mole, sank the disabled boat burning close by, and took the "Botha" in tow. This was the last of the long series of Dover raids.

The war had become more and more a war of straits and passages, but it was not till 1918 that minelaying was carried into the Cattegat. It had been in the early part of the war a sort of "No Man's Sea," but Germany began gradually to reach out into it, and in 1917 her ships were regularly cruising there. The sweep on Nov. 2 1917 had revived all her old fears, but no minefields had yet been laid there. In Feb. 1918 a deep minefield was laid off the Skaw, and another on April 15 some 10 m. N.E. of Laeso. This was laid by the "Princess Margaret" and "Angora," supported by vessels of the 6th L.C.S. and 13th Flotilla, and escorted by the "Valentine" and "Vimiera," which sank 10 German trawlers off Anholt. The discovery of the mines seems to have caused serious apprehension in German naval circles, but the operation was not repeated.

At Dover a plan was maturing to supplement the closure of the Straits by the blocking of Zeebrugge and Ostend. This would seal up not only the Flanders submarines but the destroyers there as well, which formed a constant threat to the barrage and its patrols. The enterprise was a daring one, but the plans were carefully made and skilfully performed on the night of April 22-23. The "Vindictive" (Capt. Alfred F. Carpenter) went alongside the Mole to draw the fire from the three blocking ships, and though only two of the latter achieved their object, the whole attack remains a great and inspiring example of careful planning and heroic execution. At Ostend the attempt miscarried, and a second attempt made by the "Vindictive" on May 9 also failed (*see* ZEEBRUGGE).

As the "Vindictive" was returning from her Zeebrugge venture the German fleet was putting out to sea. This was its last excursion and was directed against the Scandinavian convoys. The fleet left at 6 A.M. on April 23; von Hipper led the way with his battle-cruisers, the 1st Scouting Group, the 2nd Scouting Group and 2nd Flotilla. Behind him came the battle-fleet, consisting of the 3rd, 1st and 4th Squadrons, mustering 17 battleships, with the 4th Scouting Group and 1st, 6th, 7th and 9th Flotillas. In the morning of the 24th von Hipper was off the Norwegian coast when one of the "Moltke's" propellers was flung off its shaft, causing the turbine to race; the auxiliary condenser discharge was penetrated by a large fragment of metal and the engine-room flooded. Von Hipper went on to the north with his squadron, sending the "Moltke," which could still go 13 knots, back to the battle-fleet. By 7 A.M., when she had reached a position 40 m. S.W. of Stavanger, her speed was reduced to 4 knots, and she sent out a signal for help. The battle-fleet sighted her at 9:40, and the "Oldenburg" took her in tow. Von Hipper had turned back on getting the "Moltke's" signal, but hearing of the arrival of the battle-fleet he turned north again and ran up as far as lat. 60° N. Nothing had been seen of the British convoy, and the battle-fleet turned back with the "Moltke." Covered by the fleet she reached List (some 55 m. from Heligoland) at 6:50 P.M., where she was torpedoed by E42 (Lt. C. H. Allen), but got safely home.

A worse day for the excursion could not have been chosen. The homeward-bound convoy of 34 ships had left Norway on April 22, and at 8 A.M. on the 24th, when von Hipper was off the Norwegian coast, was within 50 m. of the Forth, while the outward-bound convoy of 47 ships was getting ready to leave the river. Not a single ship was anywhere near the Norwegian coast, and the sortie was futile. It had, however, many ramifications, and an important conference on the subject of convoys was held in the Forth on April 29, attended by the C.N.S. (Adml. Sir Rosslyn Wemyss), the D.N.I. (Rear-Adml. Sir W. R. Hall), and the Director of Plans (Capt. C. T. M. Fuller). There it was decided to alter the Scandinavian route to the northward of 61° N. so as to increase the chance of intercepting an attack on it. The incident had another interesting aspect. Up to the moment when the "Moltke" began to ask for help, no indication had been received by wireless directionals of the German fleet being at sea. Submarine J4 had seen it at 7 P.M. on April 23, but the report had not reached the c.-in-c., who was disturbed at finding the whole of the German fleet off the Norwegian coast without his knowledge. The disadvantages of relying too exclusively on wireless directionals was clearly demonstrated, and the utility of the submarines in reconnaissance work confirmed.

This was the last excursion of the German fleet, and ranks in importance with that of Jutland and Aug. 19 1916. In the north a stupendous effort was being made with the help of the U.S. navy to close the northern exit to submarines, and during the remainder of 1918 the Grand Fleet was largely occupied in escorting and covering the minelaying squadrons.

One of the last important operations in the North Sea was the bombing of the Zeppelin sheds at Tondern, near Sylt (Schleswig-Holstein), on July 19 1918. This was made by the aircraft carrier "Furious," supported by five battleships of the First Battle Squadron ("Repulse" class), and escorted by the 6th L.C.S. and a number of destroyers. The "Furious" was an immense cruiser (20,000 tons, 30 knots) of the same type as the "Courageous" and "Glorious," originally designed for Lord Fisher's Baltic campaign, and she had been converted into an aircraft carrier. The attack was made by seven aeroplanes—130 H.P. single-seater "Camels"—flown off her deck, each

carrying two 50-lb. or 65-lb. bombs. One machine went wrong soon after starting and was picked up. The others reached their objective and set fire to a double Zeppelin shed which was burnt out. Two got safely back; one fell into the sea and the pilot was drowned; three came down in Denmark where the pilots were interned. The attack is interesting as representing the stage of development reached by naval aircraft during the war. On Aug. 11 a coastal motor-boat and aircraft operation was carried out in the Bight on the Frisian coast supported by a strong force. A Zeppelin was brought down by the aircraft, but enemy aircraft overpowered the coastal motor-boats, three of which were sunk and three more lost.

In the Mediterranean the summer of 1918 saw one of the most brilliant exploits of the war by Comm. Luigi Rizzo, which seriously depleted Austria's already scanty tale of battleships.

*Mediterranean.*—The course of the war in that sea may be briefly summarized. In its main features the situation was analogous to that in the North Sea. The Straits of Otranto (40 m. wide) corresponded to the Straits of Dover, and had been closed by the arrival of the French fleet on Aug. 16 1914.

The Austrians then had three dreadnoughts ("Viribus Unitis," "Tegetthof," "Prinz Eugen") to oppose to France's two ("Courbet" and "Jean Bart"). The torpedoing of the "Jean Bart" by the Austrian U12 on Dec. 21 1914 led to the withdrawal of the battleships; and the sinking of the a.c. "Leon Gambetta" on April 26 by Austrian U5 with the loss of 614 men had much the same effect as the loss of the "Hogue," "Aboukir" and "Cressy" in the North Sea. France withdrew her forces from the Adriatic and posted them outside the Straits.

The intervention of Italy on May 24 1915 gave the Allies eight dreadnoughts ("Jean Bart," "Courbet," "Paris," "France," "Cavour," "Giulio Cesare," "Leonardo da Vinci," "Dante Alighieri") against the Austrian three. The situation was, however, complicated by the contiguity of three Allied forces in the same area. The French c.-in-c., Adml. Boué de Lapeyrère, exercised the supreme command, but the Duc d'Abruzzi, c.-in-c. of the Italian fleet, directed operations in the Adriatic, where he was reinforced by four British light cruisers, twelve French destroyers and seven French submarines. When Italy declared war on Austria in May 1915 she withdrew her dreadnoughts from the Adriatic and stationed them at Taranto. The advent of the Dardanelles campaign led to the appointment of the British Adml. de Robeck as Vice-Admiral Eastern Mediterranean, and in this area and that of Egypt the French c.-in-c.'s virtual authority was actually exercised by the British admiral. In Syrian waters the responsibility was not so clearly defined. There one of the principal objectives early in the war had been the 10-m. stretch of coast road running through Alexandretta on the main road from Adana to Aleppo. It was shelled by the British cruiser "Doris" (Capt. Frank Larken) in Dec. 1914, but after the commencement of the Dardanelles operations the observation of the Syrian coast was taken over by the French. The dominant feature of Mediterranean strategy lay in the closure of the Straits of Otranto by the overwhelming force of the Allies. The Austrian fleet never dared to try and pass it, while in the Adriatic the control was enforced by the submarine, and in its narrow waters both sides were deprived by its menace of the use of their principal instrument of war.

When Serbia collapsed in 1915 under Mackensen's hammer-like blows, the remnants of the army fell back on Albania, and its transport to Corfu formed the principal naval operation of that year. An army of 110,000 men was carried 90 m. by sea without the loss of a single transport. The attempt to close the Straits of Otranto led to a repetition there of the Dover raids (June 1, July 1, Dec. 22–3 1916, May 15 1917, April 12–3 1918). On Dec. 9 1917 a bold attack was made by two little Italian torpedo craft (Comm. Rizzo) on Trieste, and the old battleship "Wien" (5,600 tons, 4 9·6-in.) was sunk. This was followed on May 14 1918 by a similar exploit, when Comm. Mario Pellegrini penetrated the roads at Pola with a little vessel, the "Grillo," designed to climb the net defence like a tank, and apparently torpedoed an Austrian warship. Under Vice-Adml. Count Thaon de Revel, the Italian c.-in-c., the Otranto barrage was greatly strengthened, and its pressure was being severely felt by the German submarines in 1918. The conditions there were very different from those at Dover. At Dover tides were strong and depths comparatively small, varying from 16 to 30 fathoms; in the Straits of Otranto the tide was inappreciable but the depths were great, varying from 200 to 500 fathoms and making mining, except in the form of a net barrage, impracticable. The Austrian battle-fleet, spurred on by Germany, sallied out on June 10 1918 to make a raid on it in force, but were met by Comm. Luigi Rizzo with two small motor-craft off Premuda I., some 50 m. from Pola. Evading a strong escort of destroyers he sent two torpedoes into the dreadnought "Szent Istvan" ("St. Stephen"), reducing the scanty number of Austrian dreadnoughts from four to three, and sending them disconsolately home. In spite of the preponderance of the French and Italian fleets there was a tendency in the Mediterranean, as in the North Sea, to think too exclusively in terms of battle squadrons. The French fleet, now mustering seven dreadnoughts, lay at Corfu, and carried out manœuvres and target practice which would have been immensely useful if there had been an enemy to fight. Meanwhile the direction of the war against the submarine drifted largely towards Malta, where it was exercised by the British c.-in-c. (Vice-Adml. Hon. Sir Somerset Gough-Calthorpe). Early in the war the Mediterranean had been mapped out in geographical sectors for anti-submarine work, in much the same way as the coastal areas allotted to auxiliary patrol flotillas at home. Useful for purposes of administration and supply, the system was a vicious one strategically, for it impeded unity of command and made it difficult to establish uniformity in work affecting the whole area, such as convoy. To ensure better coördination it had been decided at Paris on Nov. 29 1917 to create an Allied Naval Council. This consisted of the naval representatives of the Allies—Sir Eric Geddes, Adml. Wemyss (British), Vice-Adml. de Bon (France), Vice-Adml. di Revel (Italy), Rear-Adml. Funakoshi (Japan), Vice-Adml. W. S. Sims (United States)—and its influence was particularly beneficial in the Mediterranean. When a possibility arose of the Russian dreadnoughts in the Black Sea being used by Germans, the situation was met by the dispatch of the "Superb" and "Temeraire" from England and of four French pre-dreadnoughts to Lemnos (Aegean).

An attack was made on Durazzo, the Austrian naval base, 50 m. from the Straits, on Oct. 2 by a considerable Allied naval force, including a number of American submarine chasers, and an enemy destroyer was sunk in the harbour. On the night of Oct. 31–Nov. 1 1918, when the Austrian navy was already in the hands of the Yugoslavs, an Italian boat entered Pola and sank the dreadnought "Viribus Unitis."

On the Syrian coast, a naval force of French and British ships had coöperated in the bombardment of Gaza on Oct. 30 1917, and had maintained the army's communications by sea from Egypt to Haifa, Beirut and Tripoli, with the loss by submarine attack of the monitor M15 and the destroyer "Staunch" on Nov. 11 1917.

*Mesopotamia, Archangel, Cameroon, British East Africa.*—In three great river expeditions, too, the navy played an important part; one up the Dvina in the icy waters of the White Sea, another up the Tigris in the torrid marshes of Mesopotamia, and the third in the swampy creeks of the Duala in Cameroon. In the first Mesopotamia campaign, which ended with the investment of Gen. Townshend in Kut on Dec. 2 1915, the naval force consisted at first of the sloops "Espiegle" (Comm. Wilfred Nunn, 6 4-in., 2 3-pdr.) and "Odin" (4 4-in., 2 3-pdr.), the Indian Marine paddle-ship "Lawrence" (4 4-in., 4 6-pdr.), and three small armed vessels, the "Miner," "Lewis Pelly" (a small yacht, 2 3-pdr.), and "Shaitan" (1 12-pdr. 8 cwt.) under Capt. C. Hayes Sadler of the "Ocean."

The principal base was at Basra (or Bussorah), the old emporium of the Indian overland route, 70 m. up the Shatt el 'Arab

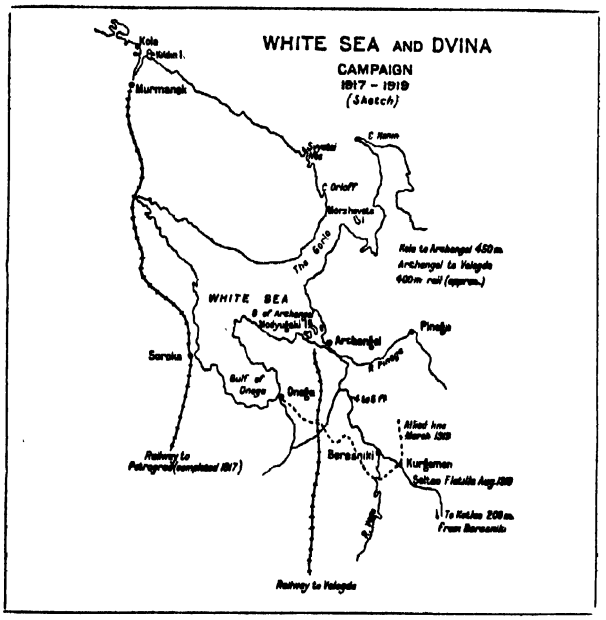
barrage about 12:55 A.M. There they opened fire on the trawler "James Pond," a searchlight vessel, and set her on fire; then proceeding slowly to the N.W. along the drifter line they sank the drifters "Cloverbank," "Cosmos" and "Jennie Murray." One of these seems to have sent up a green light, which led to a general retirement towards Dover, but two more drifters, the "Christina Craig" and "Silver Queen," were met and sunk by the enemy as he retired to the east. Meanwhile the monitor M26 and the destroyer "Syren" remained serenely at their posts under the impression that the firing was associated with an air raid. M26 saw a green light to the southward about 1 A.M., and without repeating the signal ran down there at full speed (9½ knots), and must have passed fairly close to the enemy, but finding everything quiet returned to the N.E. Varne about 2:10 A.M. By this time the firing had been heard at Dover and the rear-admiral asked for its reason at 1:28, but it was not till 2:52 that he heard that M26 saw a green light.

One more glimpse was caught of the enemy. About 2:20 the "Termagant," with the Eastern Barrage Patrol, was in about the middle of the Straits on a S.W. course, when the "Amazon" (2 4-in.), the last ship in the line, caught sight of three destroyers stealing past about 400 yd. off. She thought they were on their way to Dunkirk, and though they failed to reply to her challenge reported them as British. The senior officer (Comm. M. R. Bernard) was not satisfied, and asked if they had replied to the challenge, but by the time the question and answer got along the line the enemy were out of sight. By 2:30 evidence of a raid was taking shape. Reports of burning drifters and survivors were coming in, but it was not till 3:18 that the "Termagant's" report of passing three destroyers came in and banished all doubts. The losses inflicted by the enemy were seven drifters and one trawler sunk and three drifters and one minesweeper damaged. Had the alarm gone and been repeated immediately the enemy was seen the losses would have been less and the enemy might have suffered more.

They were not so fortunate, however, a month or so later. On March 21 the destroyers "Botha" (Comm. Roger Rede, 2 4.7-in., 2 4-in.) and "Morris" (Lt.-Comm. P. R. Percival, 3 4-in.) were lying in Dunkirk, with three French destroyers close by, when a burst of firing was heard off shore at 3:30 A.M. The British slipped, and passing through the Zuidcoote Pass, a narrow channel between the Dunkirk and Ostend roads, came upon the German destroyers retiring. The exploit of the "Broke" was repeated. The "Botha" rammed a German at full speed and cut it in half. Another was disabled by the fire of the two boats. A torpedo then hit the "Botha" in a coal-bunker and brought her to a full stop, while the enemy disappeared towards Ostend with the "Morris" in chase. She returned after seeing them enter Ostend Mole, sank the disabled boat burning close by, and took the "Botha" in tow. This was the last of the long series of Dover raids.

The war had become more and more a war of straits and passages, but it was not till 1918 that minelaying was carried into the Cattegat. It had been in the early part of the war a sort of "No Man's Sea," but Germany began gradually to reach out into it, and in 1917 her ships were regularly cruising there. The sweep on Nov. 2 1917 had revived all her old fears, but no minefields had yet been laid there. In Feb. 1918 a deep minefield was laid off the Skaw, and another on April 15 some 10 m. N.E. of Laeso. This was laid by the "Princess Margaret" and "Angora," supported by vessels of the 6th L.C.S. and 13th Flotilla, and escorted by the "Valentine" and "Vimiera," which sank 10 German trawlers off Anholt. The discovery of the mines seems to have caused serious apprehension in German naval circles, but the operation was not repeated.

At Dover a plan was maturing to supplement the closure of the Straits by the blocking of Zeebrugge and Ostend. This would seal up not only the Flanders submarines but the destroyers there as well, which formed a constant threat to the barrage and its patrols. The enterprise was a daring one, but the plans were carefully made and skilfully performed on the night of April 22-23. The "Vindictive" (Capt. Alfred F. Carpenter) went alongside the Mole to draw the fire from the three blocking ships, and though only two of the latter achieved their object, the whole attack remains a great and inspiring example of careful planning and heroic execution. At Ostend the attempt miscarried, and a second attempt made by the "Vindictive" on May 9 also failed (*see* ZEEBRUGGE).



As the "Vindictive" was returning from her Zeebrugge venture the German fleet was putting out to sea. This was its last excursion and was directed against the Scandinavian convoys. The fleet left at 6 A.M. on April 23; von Hipper led the way with his battle-cruisers, the 1st Scouting Group, the 2nd Scouting Group and 2nd Flotilla. Behind him came the battle-fleet, consisting of the 3rd, 1st and 4th Squadrons, mustering 17 battleships, with the 4th Scouting Group and 1st, 6th, 7th and 9th Flotillas. In the morning of the 24th von Hipper was off the Norwegian coast when one of the "Moltke's" propellers was flung off its shaft, causing the turbine to race; the auxiliary condenser discharge was penetrated by a large fragment of metal and the engine-room flooded. Von Hipper went on to the north with his squadron, sending the "Moltke," which could still go 13 knots, back to the battle-fleet. By 7 A.M., when she had reached a position 40 m. S.W. of Stavanger, her speed was reduced to 4 knots, and she sent out a signal for help. The battle-fleet sighted her at 9:40, and the "Oldenburg" took her in tow. Von Hipper had turned back on getting the "Moltke's" signal, but hearing of the arrival of the battle-fleet he turned north again and ran up as far as lat. 60° N. Nothing had been seen of the British convoy, and the battle-fleet turned back with the "Moltke." Covered by the fleet she reached List (some 55 m. from Heligoland) at 6:50 P.M., where she was torpedoed by E42 (Lt. C. H. Allen), but got safely home.

A worse day for the excursion could not have been chosen. The homeward-bound convoy of 34 ships had left Norway on April 22, and at 8 A.M. on the 24th, when von Hipper was off the Norwegian coast, was within 50 m. of the Forth, while the outward-bound convoy of 47 ships was getting ready to leave the river. Not a single ship was anywhere near the Norwegian coast, and the sortie was futile. It had, however, many ramifications, and an important conference on the subject of convoys was held in the Forth on April 29, attended by the C.N.S. (Adml. Sir Rosslyn Wemyss), the D.N.I. (Rear-Adml. Sir W. R. Hall), and the Director of Plans (Capt. C. T. M. Fuller). There it was decided to alter the Scandinavian route to the northward of 61° N. so as to increase the chance of intercepting an attack on it. The incident had another interesting aspect. Up to the moment when the "Moltke" began to ask for help, no indication had been received by wireless directionals of the German fleet being at sea. Submarine J4 had seen it at 7 P.M. on April 23, but the report had not reached the c.-in-c., who was disturbed at finding the whole of the German fleet off the Norwegian coast without his knowledge. The disadvantages of relying too exclusively on wireless directionals was clearly demonstrated, and the utility of the submarines in reconnaissance work confirmed.

This was the last excursion of the German fleet, and ranks in importance with that of Jutland and Aug. 19 1916. In the north a stupendous effort was being made with the help of the U.S. navy to close the northern exit to submarines, and during the remainder of 1918 the Grand Fleet was largely occupied in escorting and covering the minelaying squadrons.

One of the last important operations in the North Sea was the bombing of the Zeppelin sheds at Tondern, near Sylt (Schleswig-Holstein), on July 19 1918. This was made by the aircraft carrier "Furious," supported by five battleships of the First Battle Squadron ("Repulse" class), and escorted by the 6th L.C.S. and a number of destroyers. The "Furious" was an immense cruiser (20,000 tons, 30 knots) of the same type as the "Courageous" and "Glorious," originally designed for Lord Fisher's Baltic campaign, and she had been converted into an aircraft carrier. The attack was made by seven aeroplanes—130 H.P. single-seater "Camels"—flown off her deck, each

(Lt.-Comm. Chas. Cartwright) was badly hit. But the flotilla forced its way through, and opening a heavy fire with its 6-in. guns at close range on the Turks converted the retreat into a rout, recapturing the "Sumana" and forcing the "Basra," "Pioneer" and "Firefly" aground. 'Asiziya was reached on March 1 and the Union Jack hoisted at Bagdad on March 11 1917. Shortage of river transport was at the root of the British troubles in Mesopotamia, and the failure there and in the Dardanelles was largely due to the glamour of a possible victory concealing the technical difficulties in its path. In Mesopotamia, when these were realized, victory was achieved.

The expedition to Archangel and up the Dvina was of a different nature. It began only in 1918 and survived the war. The closure of the Baltic and the Black Sea had enormously enhanced the importance of the Arctic coast, and a stream of munitions for Russia passed daily along that track. There were two ports there, Murmansk in Kola Bay and Archangel, the former ice free, the latter accessible to ships of 24 ft. from July to October. From Lerwick to Kola Bay was 1,152 m., and from Murmansk a railway was being built to Petrograd, but it was not completed till 1917. Archangel remained the only port of entry on the Russian railway system, and to establish direct telegraphic connexion a cable 1,427 m. long was laid from Peterhead to Murmansk in Jan. 1915. At both ports British patrol flotillas were stationed, but up to 1917 they were engaged only in minesweeping and escort work. In 1917 when Russia collapsed the whole position became precarious. Vast quantities of supplies were lying at Archangel. In 1917 some 600,000 tons of warlike stores had entered the port in addition to 600,000 tons of coal. As it was thought possible that the Germans might send a force against Murmansk, the British cruiser "Cochrane" and the French cruiser "Admiral Aube" were sent in Feb. 1918 to reinforce the old battleship "Glory" there. It was then merely a question of retaining the hold on the coast. By May 1918 the Germans were in Finland, and it was decided to send a force of 600 British and 2,000 other troops to Archangel and 1,500 British and 5,000 others to Murmansk. In June 1918 Sir Eric Geddes arrived, to gain an idea of the situation on the spot. It was then decided by the Supreme War Council to send 5,000 troops to occupy Archangel and push on down to Vologda, join hands with Kolchak's force and endeavour to reëstablish Russia's resistance to Germany. The Archangel force arrived at the end of June 1918. The cruisers "Admiral Aube," "Attentive" and "Nairana" (aircraft carrier) pushed on to Archangel, and the town was occupied with little resistance on Aug. 2 1918.

The campaign resolved itself into the Allied troops (French and British) under Gen. Poole advancing up the railway, which ran 400 m. to the southward to Vologda, in conjunction with a flotilla working on the river Dvina. The latter consisted of two monitors, M23 and M25, four Russian river gun-boats, and two Russian motor-launches, under Capt. Ed. Altham. Beresniki, some 200 m. from Archangel, was reached on Sept. 3 1918, and the enemy were driven up the river, but by Oct. 19 the flotilla had to retire when the river began to freeze.

The campaign survived the war. In March 1919 it was decided to withdraw all forces from the N., and the North Russian Relief Force, consisting of a couple of brigades, was sent in May 1919 to facilitate the retirement. The flotilla now consisted of 6 monitors (M23, 25, 26, 27, 31, 33), four Chinese gunboats ("Glowworm," "Cockchafer," "Cicala," "Cricket" 2 6-in., 2 3-in., 6 maxims), four minesweepers and six coastal motor-boats, and a last push was made up the river in June. Then suddenly the plans at home were altered. It was proposed that Gen. Ironsides should push up the Dvina to Kotlas, 200 m. above Beresniki, through stretches of river little known and with little more than 3½ ft. of water. But at the end of June the river commenced to fall. By July 7 there was only 4 ft. of water between Archangel and Beresniki. The general's hope of reaching Kotlas fell with the river. His Russian troops mutinied, and it was only the arrival of the relief force which saved the situation. The flotilla gradually fell down the river, blowing up M25 and M27, which could not be got down in time. By Sept. 27 1919 the evacuation was complete,—leaving N. Russia to the Bolsheviks and winter.

In conjunction with Capt. Cyril Fuller's expedition in Cameroon, these two river expeditions supply an almost inexhaustible store of experience in river warfare. The work of the navy in the latter expedition consisted in the sweeping of the Duala estuary and the establishment of a base, the clearance of the enemy from its tortuous and narrow creeks, the transport of the military up the various branches of the river, and the seizure of the port of Victoria, Nov. 14 1914, on the coast. The vessels which took part in it were the "Cumberland" (Capt. C. M. Fuller), "Challenger" (Capt. C. P. Beatty Pownall), the gunboat "Dwarf" (Comm. F. E. Strong, 2 4-in., 4 12-pdr.), the "Ivy," a Nigerian vessel, and a number of smaller craft. Duala was occupied by Sept. 27, when eight of the Woermann line were captured, and though the final surrender did not take place till Feb. 28 1916, the colony was virtually captured by the end of 1914.
